Abstracts of the 20th International Myeloma Society Annual Meeting

Athens, Greece
September 27–30, 2023

About the 20th IMS Annual Meeting

The 20th International Myeloma Society Annual Meeting, under the auspices of the International Myeloma Society (IMS), is devoted to fostering scientific and clinical exchange on the latest breakthroughs in multiple myeloma and related plasma cell disorders. Scientific programming at the 20th IMS Annual Meeting will cover the latest genomic advances, new drug targets and agents, immunotherapeutic approaches including Car T-cell therapies, COVID-19 in multiple myeloma, and more.

This book compiles the abstracts from oral and poster session presentations at the 20th IMS Annual Meeting held at the Megaron Athens International Conference Centre in Athens, Greece from September 27–30, 2023. The abstracts are reproduced as submitted by the author and accepted by the Scientific Program Committee. They appear in order of abstract code and track.

About the International Myeloma Society

The International Myeloma Society (IMS) is a professional, scientific, and medical society established to bring together clinical and experimental scientists involved in the study of myeloma.

The purpose of this society is to promote research, education, clinical studies (including diagnosis and treatment), workshops, conferences, and symposia on all aspects of multiple myeloma worldwide.

The IMS is a membership organization comprised of basic research scientists, and clinical investigators in the field along with physicians and other healthcare practitioners.

IMS is governed by a Board of Directors representing practices from around the world and encourages and promotes the study of this expanding field through its annual meeting.

Clinical Lymphoma, Myeloma and Leukemia is the official journal of the International Myeloma Society (IMS).

Introduction: Although asymptomatic smoldering multiple myeloma (SMM) often precedes symptomatic MM, most patients affected by SMM are only offered active observation, which increases their frustration and anxiety. A link between gut microbiota and MM aggressiveness has been proposed. We previously showed that the human commensal Prevotella heparinolytica (P.h.) expands Th17 cells that migrate from the gut to the bone marrow (BM) where they favor the expansion of neoplastic plasma cells. At odds, P. melaninogenica (P.m.) limits Th17 cell expansion, thus restraining MM aggressiveness. Similarly, in SMM patients, higher levels of BM IL-17 predicted accelerated disease. Because the gut microbiota also contributes to the clinical efficacy of immune checkpoint blockade (ICB) and neoplastic plasma cells selectively express PD-L1, we hypothesized that modulation of the gut microbiota by P.m. limits the expansion of Th17 cells in mice affected by asymptomatic MM, thus fully exploiting the therapeutic potential of anti-PD-L1 against MM. **Methods:** C57BL/6J mice challenged with MM cells and Vk*MYC mice affected by asymptomatic MM were treated with P.m. and/or anti-PD-L1 and disease progression was monitored by paraprotein quantification in blood. Anemia provided clinical evidence of symptomatic disease. Modification of the gut microbiota composition after the treatment were assessed by16S rRNASeq and shotgun metagenomics. At sacrifice, gut, spleen and BM were analyzed by flow cytometry. To clarify the mechanism of Th17 induction by the gut microbiota, we conducted in vitro assays. **Results:** Administration of P.m. to mice challenged with Vk*MYC-derived MM cells increased the therapeutic efficacy of anti-PD-L1 antibodies limiting the expansion of Th17 cells. Translating the approach in the context of SMM-to-MM evolution, treatment with P.m. in transgenic Vk*MYC mice at the phase of asymptomatic (Early)-MM significantly delayed the progression towards symptomatic (Late)-MM. When P.m. was combined with anti-PD-L1 we further delayed the evolution from Early-MM to Late-MM. Mechanistically, P.m. restrained the expansion of gut-born Th17 cells in the BM without dampening the antitumor cytotoxic response elicited by the ICB. Thus, combination of P.m. and anti-PD-L1 resulted in more favorable Th17/T regulatory cell ratio and CD8/Th17 ratio in the BM. P.m. polarized intestinal DCs to produce less Th17-polarizing cytokines compared to P.h., which conversely promoted Th17 expansion. In vitro stimulation of both human and mouse DCs with P.m. or its conditioned medium reduced polarization of naïve T cells to Th17 cells compared to P.h. **Conclusions:** Taken together, our data support the development of microbiota-based strategies in combination with ICB to treat full-blown MM and to prevent progression of patients affected by asymptomatic SMM to full-blown disease.

immune checkpoints (IC) can constrain their anti-tumor efficacy, as occurs in CAR-T. HLA-E is overexpressed in several tumors, including metastatic cells, and correlates with a poor prognosis. Here, we have studied the impact of HLA-E and NKG2A expression in a high cohort of MM patients at different stages and we propose the combination of α-NKG2A blocking antibodies with BCMA and NKG2D-CAR NK cell immunotherapies to enhance their anti-MM efficacy. **Methods:** HLA-E and NKG2A expression was analysed in bone marrow (BM) samples from healthy donors (HD) (n=18) and MM patients (n=71) and IFNγ from these sera was quantified. HLA-E modulation by IFNγ and bortezomib (BTZ) as well as the efficacy of α-NKG2A blocking monotherapy against plasma cells (PC), within BM mononuclear cells (BMMCs) cultures, were also studied by multiparametric flow cytometry (MFC). Activated and expanded NK (NKAE) cells were obtained from HD' peripheral blood MCs (PBMCs) after stimulation with irradiated K562-mb21-41BBL cells and IL-2. NKAE cells were then purified and lentivirally transduced with either BCMA or NKG2D CAR. The combination activity of these CAR therapies with mouse and human α-NKG2A antibodies was tested in vitro against primary MM cells, PBMCs and CD34+ cells, by MFC and calcein-release assays, and in vivo using NSG-Tg hIL-15 mice bearing U-266 ffLucGFP MM cells. **Results:** MM patients at relapse/progression exhibit higher HLA-E expression in malignant PC compared to healthy populations and elevated NKG2A expression in NK cells. IFNγ, highly increased in MM patients' BM sera, augments HLA E expression. BTZ can diminish this effect in sensitive MM cells but not in BTZ resistant, suggesting HLA-E/NKG2A as an important IC in this relapse/refractory setting. However, mouse or human α-NKG2A monotherapy treatment does not restore MM patients' NK cells anti tumor efficacy. BCMA-CAR and NKG2D-CAR NKAE cells also have an elevated NKG2A expression and release high levels of IFNγ that augment HLA-E levels in MM cells. In this instance, the combination of CAR NKAE therapies with mouse or human α NKG2A antibodies significantly increases their cytotoxicity, degranulation and IFNγ release against MM cells along with a lack of toxicity against HD' PBMCs and CD34+ from MM patients. Differential immunophenotype after α NKG2A blockade in CAR NKAE cells is being studied by Cytof. Notably, human α-NKG2A pretreatment in NKG2D-CAR NKAE cells have significantly increased mice survival, controlling the tumor in treated mice. α-NKG2A combination with BCMA-CAR therapy is being tested. **Conclusions:** HLA-E and NKG2A are overexpressed in malignant PC and NK cells, respectively, from relapse/progression MM patients. Despite the lack of efficacy of α-NKG2A monotherapy, the combination of α NKG2A antibodies with BCMA and NKG2D-CAR therapies is able to overcome MM CAR target independent resistance in vitro and in vivo.

OA-03

Bispecific T-cell engager response is driven by pre-treatment CD8+ effector memory cells and inhibited by TIGIT+ Tregs in relapsed/refractory multiple myeloma

Ross Firestone[1], Devin McAvoy[1], Tala Shekarkhand[1], Edith Serrano[1], Issam Hamadeh[1], Alice Wang[1], Menglei Zhu[1], Dhwani Patel[1], Carlyn Rose Tan[1], Malin Hultcrantz[1], Sham Mailankody[1], Hani Hassoun[1], Urvi Shah[1], Neha Korde[1], Kylee Maclachlan[1], Heather Landau[1], Michael Scordo[1], Gunjan Shah[1], Oscar Lahoud[1], Sergio Giralt[1], Kinga Hosszu[1], David Chung[1], Alexander Lesokhin[1], Saad Usmani[1]

[1]Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: Teclistamab (Tec) is a CD3 x BCMA bispecific antibody approved for treating relapsed/refractory (RR) multiple myeloma (MM) based on the results of the MajesTEC-1 trial (Usmani S, et al. Lancet 2021, Moreau P, et al. N Engl J Med 2022), where patients with exposure to prior anti-BCMA therapy were excluded. While the therapy demonstrated impressive efficacy, little is known about clinical and patient-specific immunophenotypic predictors of response to therapy. Additionally, the efficacy of Tec in patients with prior anti-BCMA therapy exposure has yet to be assessed. **Methods:** We performed an IRB-approved study profiling the peripheral blood T-cell repertoire from pre-treatment PBMC samples from a 14-patient sub cohort (9 responders, 5 non-responders) of commercial Tec patients via high-dimensional spectral cytometry using a 33-color panel including lineage (CD4, CD8, CD25, CD127, CD45RA, CD45RO, CCR7, CD62L, CD28, CD95), exhaustion (PD-1, LAG3, TIM3, CTLA-4, TIGIT, OX-40, 4-1BB, ICOS, BTLA, CD57), and activation markers (CD69, HLA-DR, CD25, CD27) among others. We also performed a retrospective analysis of clinical outcomes for 41 commercial Tec patients (7 median prior lines of therapy, 23/41 (56%) with prior anti-BCMA therapy exposure) treated as of 05/01/2023. Results were correlated to MM cell BCMA expression. **Results:** Tec responders had enrichment for both CD8+ effector memory T-cells (>6-fold increase, p = 0.03) and CD8+ effector memory cells re-expressing CD45RA (>5-fold increase, p = 0.02). Tec non-responders were enriched for TIGIT+ Tregs (3-fold increase, p = 0.03). No differences between PD-1, CTLA-4, LAG-3 or TIM-3 expression were observed in responders vs non-responders. Clinical outcome analysis identified a high CD8+:CD4+ ratio as predictive of response, and CRS during step-up dosing was strongly associated with Tec efficacy. Among the 31/41 response evaluable patients, the overall response rate for commercial Tec patients with prior anti-BCMA therapy exposure was 58% (11/19 patients) and was similar for anti-BCMA therapy naïve patients. No differences in BCMA expression were noted between responding and non-responding patients or between anti-BCMA exposed and anti-BCMA therapy naïve patients. **Conclusions:** Tec is an effective therapy in RRMM even in patients with prior anti-BCMA therapy exposure. A pre-Tec T-cell population enriched with highly cytotoxic effector T-cells associates with response to therapy, while suppressive TIGIT+ Tregs associate with nonresponse, suggesting a potential therapeutic role for TIGIT blockade or CD25+ cell depletion to enhance the therapeutic efficacy of Tec and other bispecific antibodies. Clinical and translational data from additional enrolled patients will be presented at the meeting.

immune checkpoints (IC) can constrain their anti-tumor efficacy, as occurs in CAR-T. HLA-E is overexpressed in several tumors, including metastatic cells, and correlates with a poor prognosis. Here, we have studied the impact of HLA-E and NKG2A expression in a high cohort of MM patients at different stages and we propose the combination of α-NKG2A blocking antibodies with BCMA and NKG2D-CAR NK cell immunotherapies to enhance their anti-MM efficacy. **Methods:** HLA-E and NKG2A expression was analysed in bone marrow (BM) samples from healthy donors (HD) (n=18) and MM patients (n=71) and IFNγ from these sera was quantified. Introduction: Robust biomarkers of response and resistance to chimeric antigen receptor (CAR) T cell therapy in patients with relapsed/refractory multiple myeloma (RRMM) are lacking. We conducted a longitudinal single-cell multi-omics study to identify factors predicting response to BCMA-directed CAR T cells. **Methods:** Peripheral blood samples from 10 patients (8 Ide-cel; 2 Cilta-cel) were collected on the day of leukapheresis and 30 days after CAR T cell treatment. Bone marrow biopsies were performed on day 30 after CAR T cell therapy. We used 57 oligonucleotide-coupled antibodies for surface proteome analysis. Libraries for single cell BCR, TCR and RNA were generated using the 10x genomics 5' chemistry. Cell types were annotated with Seurat and WNN. scCODA identified cell type composition changes. InferCNV detected CNVs in malignant plasma cells. Ligand-receptor signaling was inferred with iTalk and CellPhoneDB. CAR T cell in vitro functionality was tested through cytotoxicity assays. For analyses patients were divided by their response to CAR T cell therapy on day 30 after infusion (CR: n=5, no CR: n=5). **Results:** We sequenced 178,142 cells (median 7,990 cells/sample, range 1,569-10,972 cells) and already observed differences between patients in CR and no CR at leukapheresis. CR patients harbored more CD8+ TEM and NK cells but fewer monocytes. Non-responders showed recurrently higher PIM kinase expression in monocytes, dendritic and NK cells as well as higher protein expression of immune checkpoints on monocytes (CD39) and NK cells (CD94). Cell-cell interaction analysis identified inhibitory communication of monocytes with NK and CD8+ T cells in non-responders. Since we detected an immunosuppressive environment in non-responders at leukapheresis, we aimed at characterizing the functionality of manufactured CAR T cells. CAR T cells isolated from patients in CR and no CR at day 7 post-infusion, effectively eliminated MM cells (U-266), indicating that also CAR T cells from non-responders remained functional in vitro. Comparing single-cell transcriptomes of CAR T cells isolated from patients in CR who received Cilta-cel or Ide-cel, we noticed an upregulation of genes associated with cell cycle regulation, exhaustion/senescence, and chemotaxis in Cilta-cel CAR T cells. Surface proteomics revealed that hyperexpanded CAR T cells displayed a more exhausted and senescent phenotype, characterized by higher expression levels of immune checkpoints and NK cell receptors (PD1, CD57, CD94), as well as lower expression levels of markers associated with activation. In contrast, non-hyperexpanded CAR T cell clonotypes exhibited a protein expression profile marked by downregulation of exhaustion/senescence markers (e.g., TIM-3, KLRB1, KLRG1, and CD337). **Conclusions:** Our study indicates an association between an immunosuppressive microenvironment that is already present at time of leukapheresis and resistance to CAR T cell therapy in RRMM.

Introduction: Forimtamig, a GPRC5DxCD3 T-cell-engaging bispecific antibody (BsAb), is currently being evaluated in patients (pts) with RRMM. In a first-in-human Phase 1a dose-escalation study (BP42233; NCT04557150), forimtamig induced deep and durable responses in heavily pre-treated pts and had a safety profile consistent with its MOA and target expression (Carlo-Stella et al. ASH 2022). We evaluated clinical responses in high-risk subgroups. **Methods:** Eligible pts had RRMM and ≥1 prior line(s) of therapy (LOT), and were refractory to a PI and an IMiD. Pts received

forimtamig target doses of 0.018–10mg either IV or SC with prior administration of 2 step doses. Efficacy was evaluated in the following subgroups: age ≥65 years, >4 prior LOT, triple-class and penta-drug refractory disease, prior BCMA-targeted therapy, high-risk cytogenetics (del(17p), t(4;14), t(14;16)), 1q21 gain (irrespective of other high-risk aberrations), ISS disease Stage III at baseline, high tumor burden (>median sBCMA at baseline), and presence of soft tissue plasmacytoma (bone-based and extramedullary). The primary endpoint was objective response rate (ORR) assessed per IMWG criteria. **Results:** As of January 25, 2023, 120 pts in the efficacy-evaluable population had received forimtamig during the dose escalation. Median age was 63 years, and median time from diagnosis to enrollment was 6.2 years (range: 0.4–30.7). ORR across all dose levels was 66.7% (very good partial response or better: 54.2%), with a median duration of response of 12.2 months (range: 0.03–20.8) and 61.3% of responders with ongoing responses at cut-off. High ORRs were observed across all risk groups. ORRs in pts aged ≥65 years (n=52) and in pts with >4 LOT (n=49) were 71.2% and 63.3%, respectively. Pts with high-risk cytogenetics (n=33) had an ORR of 63.4%, while those with 1q21 gain (n=15) had an ORR of 86.7%. ORRs in pts with triple-class (n=81) and penta-drug (n=45) refractory disease were 60.5% and 57.8%, respectively. Twenty-nine pts had received prior BCMA-targeted therapy (n=19 with antibody-drug conjugates [ADCs], n=5 with BsAbs, and n=5 with CAR T-cells, including n=3 with ADCs and BsAbs or CAR T-cells). ORRs were 51.2% in all pts, 47.4% in ADC, 42.9% in BsAb, and 66.7% in CAR T-cell. ORRs in pts with ISS disease Stage III (n=24) and extramedullary disease (n=28), factors known to be of prognostic relevance for T-cell-directed therapy, were 70.8% and 50.0%, respectively. Levels of sBCMA, a potential novel biomarker for tumor load and disease monitoring, above (n=54) and below (n=55) the median at baseline (327 ng/ml) were associated with ORRs of 55.6% and 80.0%, respectively. **Conclusions:** Forimtamig induced objective responses in all subgroups and showed high clinical activity in pts with high-risk features that are known to be clinically relevant in T-cell-directed therapy. Optimization of the forimtamig dose and schedule is ongoing, as well as evaluation of long-term treatment benefit, including in pts with high-risk disease.

Introduction: BCMA targeted CAR-T cell therapy has clinical benefits for patients with r/r MM, but long manufacturing times and poor in vivo persistence remain unresolved problems. The T-charge platform is a novel rapid manufacturing process that reduces manufacturing time to < 2 days and preserves less-differentiated T cells in the CAR-T product. Here, we present correlative data from the ongoing Phase I trial in r/r MM (NCT04318327) of PHE885, a fully human product manufactured using the T-Charge platform. **Methods:** We studied serial samples from 32 patients who received PHE885 at the Dana-Farber Cancer Institute. PHE885 manufacturing and CAR T cell persistence were assessed in apheresis samples (APH), final product (FP), and peripheral blood (PB) following infusion using flow cytometry and CyTOF. Bulk T cell receptor (TCR) sequencing was used to monitor PHE885 repertoire diversity over time. Serum cytokines and soluble BCMA were also measured. **Results:** We have previously reported a 98% overall response rate (ORR) across all dose levels (2.5-20x10^6 CAR-T cells) and 100% ORR at >5x10^6 cell dose. Here we report immune assessment of the product and after in vivo expansion. The proportion of stem-like memory T cells (TSCM) in FP was preserved following manufacturing. CyTOF and TCR sequencing revealed that TSCM in FP had a highly activated and proliferative phenotype and significantly higher TCR repertoire diversity than memory T cells. PHE885 CAR T cells expanded rapidly after infusion reaching median peak levels of 3,118 cells/ul (range 373 to 17,865) in PB at a median of 14 days (range 10 to 27) after infusion. Cytokine release syndrome (CRS) occurred with expansion of CAR-T cells and was associated with increased serum levels of IFNg, TNFa, and IL-6. While the peak CAR-T expansion was not associated with the dose of PHE885, the frequency of TSCM in FP positively correlated with the expansion of CAR-T on day 14 after infusion. CAR-T cells at day 14 after infusion were predominately effector memory (TEM) and exhibited a highly activated and proliferative phenotype. Following peak expansion there was emergence of effector memory cells expressing CD45RA (TEMRA) over time. CAR-T cells during peak expansion in vivo had higher levels of TCR repertoire diversity than non-CAR-T cells, and post-infusion CAR-T cells shared significantly more TCR clonotypes with TSCM than with memory T cells in FP, suggesting that the highly heterogeneous CAR-T clones at peak expansion were derived from TSCM clones in FP. High levels of PHE885 persistence were observed with transgene detectable by qPCR in 67% of patients, and >10% of CD3+ T cells by flow cytometry in 39% of patients at 6 months. In patients with long-term persistence, CAR-T cells maintained a highly diverse TCR repertoire. **Conclusions:** The T-charge rapid manufacturing platform successfully preserved TSCM clones in the FP leading to a highly heterogeneous and proliferative CAR-T expansion with durable persistence.

forimtamig target doses of 0.018–10mg either IV or SC with prior administration of 2 step doses. Efficacy was evaluated in the following subgroups: age ≥65 years, >4 prior LOT, triple-class and penta-drug refractory disease, prior BCMA-targeted therapy, high-risk cytogenetics (del(17p), t(4;14), t(14;16)), 1q21 gain (irrespective of other high-risk aberrations), ISS disease Stage III at baseline, high tumor burden (>median sBCMA at baseline), and presence of soft tissue plasmacytoma (bone-based and extramedullary). Phase I Study of BCMA CAR-T using instant manufacturing platform or traditional production process for relapsed/refractory multiple myeloma therapy

Hui Liu[1], Ting Wang[1], Yazi Yang[1], Ru Feng[1], Jiangtao Li[1], Chunli Zhang[1], Jiefei Bai[1], Yanping Ding[2], Guanghua Liu[2], Fei Wu[2], Xinan Lu[2], Ting He[2]

[1]Beijing Hospital; [2]Beijing Imunopharm Technology Co., Ltd.

Introduction: Although chimeric antigen receptor (CAR)-T cell has revolutionized relapsed/refractory (r/r) multiple myeloma (MM) therapy, critical problems including tumor relapse, long vein-to-vein time, insufficient production capacity, and high cost need to be tackled. Traditional production process of autologous CAR-T (named TraditionCART) occupied 9-14 days, resulting in over 3 weeks of vein-to-vein time, high cost, and more seriously, disease progression during the production period. Here a fourth-generation BCMA CAR-T was designed, and manufactured using Instant Manufacturing Platform (named InstanCART) to shorten the production period and optimize the T cell function. Pre-clinical studies confirmed that InstanCART was rich in low differentiated T cells and showed more durable antitumor efficacy compared with TraditionCART. **Methods:** A phase 1 clinical trial (NCT04537442) was launched to evaluate the safety and efficacy of the TraditionCART and InstanCART for treating r/r MM. Patients (pts) received a single infusion of TraditionCART at the dose of 1×10^6/kg CAR-T cells, or InstanCART at the dose of 2×10^7 T cells. The primary objectives were safety and toxicity, and the secondary objectives were efficacy and pharmacokinetic profile. Expansion of CAR-T cells in pts was evaluated using flow cytometry analysis of peripheral blood. **Results:** As of May 2023, 22 pts received CAR-T infusion and finished at least 1-month follow-up, with 15 pts in TraditionCART group and 7 pts in InstanCART group. No ≥grade 3 neurotoxicity and cytokine release syndromes (CRS) were observed in both groups. TraditionCART therapy caused grade 1-2 CRS in 12/15 pts (80%), neurotoxicity in 1/15 pt (7%) and led to ≥grade 3 adverse events including thrombocytopenia (9/15, 60%), neutropenia (14/15, 93%), anemia (10/15, 67%), creatinine increased (1/15, 7%), hepatic enzymes increased (2/15, 13%), and sepsis (1/15, 7%). Meanwhile, InstanCART therapy induced grade 1-2 CRS in 7/7 pts (100%), neurotoxicity in 1/7 pt (14%), and also caused ≥grade 3 adverse events including thrombocytopenia (6/7, 86%), neutropenia (6/7, 86%), anemia (2/7, 29%), and hepatic enzymes increased (3/15, 43%). The best overall response rate (ORR) for TraditionCART was 93% (14/15), including 8sCR, 2CR, 2VGPR, 2PR and 1SD. In contrast, the best ORR for InstanCART was 100%, including 3sCR, 1VGPR and 3PR. The expansion and duration of InstanCART ($Cmax=297\times10^7$/L, $AUC0\text{-}28d=2854\times10^7$/L) were dramatically higher than that of TraditionCART ($Cmax=59.1\times10^7$/L, $AUC0\text{-}28d=708.6\times10^7$/L). There was no statistically significant difference in progression-free survival and overall survival between InstanCART and TraditionCART. **Conclusions:** InstanCART was well tolerated, and showed non-inferior efficacy and more encouraging pharmacokinetic profile compared with TraditionCART for r/r MM therapy. The clinical study is ongoing, and durable efficacies will be evaluated during long-term follow-up.

OA-08

GPRC5D-targeted CAR-T cell therapy in patients with relapsed or refractory multiple myeloma progressing after or refractory to BCMA CAR-T cell therapy: updated eesults from a phase 2 clinical trial

Jieyun Xia[1], Zhenyu Li[2], Hujun Li[1], Zhiling Yan[2], Mengdi Xu[1], Kailin Xu[2]

[1]The Affiliated Hospital of Xuzhou Medical University; [2]Blood Diseases Institute, Xuzhou Medical University, Xuzhou, Jiangsu, China

Introduction: BCMA-targeted immunotherapy has shown unprecedented results in the treatment of R/RMM, but most patients (pts) eventually develop progressive disease (PD). Therefore, additional treatment options with novel therapeutic targets are warranted. Early results from the Phase 2 trial of autologous GPRC5D chimeric antigen receptor (CAR) -T cells in pts with R/R MM(ChiCTR2100048888) demonstrated an encouraging clinical efficacy and manageable safety profile, including pts with previous anti-BCMA CAR-T cell therapy. Here, we report updated clinical data on GPRC5D CAR-T cell therapy in R/R MM pts who have progressed or developed refractory disease after anti-BCMA CAR-T therapy. **Methods:** This phase 2, single-arm study enrolled pts (18-70 years) with R/R MM. Eleven R/R MM pts with previous anti-BCMA CAR-T cell therapy were treated as part of the phase 2 study as previously reported. The primary endpoint was the proportion of pts who achieved an overall response. Safety was also assessed in eligible pts. **Results:** Eleven R/R MM pts with previous anti-BCMA CAR-T cell therapy were enrolled and underwent apheresis between November 25, 2021 and November 8, 2022. Median age was 63 (range 46-70) years and pts received a median of 5 (range 2-12) lines of therapy. Of 11 pts, 6 (55%) had extramedullary diseases, 6 (55%) had a high tumor burden, 4 (36%) had R-ISS stage III disease, and 4 (36%) had high-risk cytogenetic abnormalities. Median follow-up was 14.8 months (range 5.8-16.9). Eleven (100%) pts had an overall response, of whom 5 (45%) had a complete response (CR) or better. Two pts had received repeated anti-BCMA CAR-T cell infusions with no responses at the last time, of whom 1 patient achieved CR, and the other partial response after anti-GPRC5D CAR-T cell infusion. 8 (73%) of the 11 pts were minimal residual disease (MRD) negative in the bone marrow by multicolor flow cytometry (sensitivity: 10 -5). The median progression-free survival was 6.4 months (95% CI: 1.2 to 11.6 months). At the time of analysis, 5 (45%) pts are progression free and followed without additional therapy. We also noted robust GPRC5D-CAR expansion in the peripheral blood using qPCR with available data (peak expansion CAR DNA copies/μL, median: 22711; range: 2563- 75561). Grade 3 or higher hematological toxicities were neutropenia (10[91%]), anemia (7[64%]), and thrombocytopenia (6[55%]). Cytokine release syndrome occurred in 10 (91%) of 11 pts (all were grade 1 or 2); 5 (45%) pts received tocilizumab and 3 (27%) received dexamethasone for the management of CRS. No neurological

Phase I Study of BCMA CAR-T using instant manufacturing platform or traditional production process for relapsed/refractory multiple myeloma therapy

Hui Liu[1], Ting Wang[1], Yazi Yang[1], Ru Feng[1], Jiangtao Li[1], Chunli Zhang[1], Jiefei Bai[1], Yanping Ding[2], Guanghua Liu[2], Fei Wu[2], Xinan Lu[2], Ting He[2]

[1]Beijing Hospital; [2]Beijing Imunopharm Technology Co., Ltd.

Introduction: Although chimeric antigen receptor (CAR)-T cell has revolutionized relapsed/refractory (r/r) multiple myeloma (MM) therapy, critical problems including tumor relapse, long vein-to-vein time, insufficient production capacity, and high cost need to be tackled. Traditional production process of autologous CAR-T (named TraditionCART) occupied 9-14 days, resulting in over 3 weeks of vein-to-vein time, high cost, and more seriously, disease progression during the production period. Here a fourth-generation BCMA CAR-T was designed, and manufactured using Instant Manufacturing Platform (named InstanCART) to shorten the production period and optimize the T cell function. Pre-clinical studies confirmed that InstanCART was rich in low differentiated T cells and showed more durable antitumor efficacy compared with TraditionCART. **Methods:** A phase 1 clinical trial (NCT04537442) was launched to evaluate the safety and efficacy of the TraditionCART and InstanCART for treating r/r MM. Patients (pts) received a single infusion of TraditionCART at the dose of 1×10^6/kg CAR-T cells, or InstanCART at the dose of 2×10^7 T cells. The primary objectives were safety and toxicity, and the secondary objectives were efficacy and pharmacokinetic profile. Expansion of CAR-T cells in pts was evaluated using flow cytometry analysis of peripheral blood. **Results:** As of May 2023, 22 pts received CAR-T infusion and finished at least 1-month follow-up, with 15 pts in TraditionCART group and 7 pts in InstanCART group. No ≥grade 3 neurotoxicity and cytokine release syndromes (CRS) were observed in both groups. TraditionCART therapy caused grade 1-2 CRS in 12/15 pts (80%), neurotoxicity in 1/15 pt (7%) and led to ≥grade 3 adverse events including thrombocytopenia (9/15, 60%), neutropenia (14/15, 93%), anemia (10/15, 67%), creatinine increased (1/15, 7%), hepatic enzymes increased (2/15, 13%), and sepsis (1/15, 7%). Meanwhile, InstanCART therapy induced grade 1-2 CRS in 7/7 pts (100%), neurotoxicity in 1/7 pt (14%), and also caused ≥grade 3 adverse events including thrombocytopenia (6/7, 86%), neutropenia (6/7, 86%), anemia (2/7, 29%), and hepatic enzymes increased (3/15, 43%). The best overall response rate (ORR) for TraditionCART was 93% (14/15), including 8sCR, 2CR, 2VGPR, 2PR and 1SD. In contrast, the best ORR for InstanCART was 100%, including 3sCR, 1VGPR and 3PR. The expansion and duration of InstanCART ($Cmax=297\times10^7$/L, $AUC0\text{-}28d=2854\times10^7$/L) were dramatically higher than that of TraditionCART ($Cmax=59.1\times10^7$/L, $AUC0\text{-}28d=708.6\times10^7$/L). There was no statistically significant difference in progression-free survival and overall survival between InstanCART and TraditionCART. **Conclusions:** InstanCART was well tolerated, and showed non-inferior efficacy and more encouraging pharmacokinetic profile compared with TraditionCART for r/r MM therapy. The clinical study is ongoing, and durable efficacies will be evaluated during long-term follow-up.

GPRC5D-targeted CAR-T cell therapy in patients with relapsed or refractory multiple myeloma progressing after or refractory to BCMA CAR-T cell therapy: updated eesults from a phase 2 clinical trial

Jieyun Xia[1], Zhenyu Li[2], Hujun Li[1], Zhiling Yan[2], Mengdi Xu[1], Kailin Xu[2]

[1]The Affiliated Hospital of Xuzhou Medical University; [2]Blood Diseases Institute, Xuzhou Medical University, Xuzhou, Jiangsu, China

Introduction: BCMA-targeted immunotherapy has shown unprecedented results in the treatment of R/RMM, but most patients (pts) eventually develop progressive disease (PD). Therefore, additional treatment options with novel therapeutic targets are warranted. Early results from the Phase 2 trial of autologous GPRC5D chimeric antigen receptor (CAR) -T cells in pts with R/R MM(ChiCTR2100048888) demonstrated an encouraging clinical efficacy and manageable safety profile, including pts with previous anti-BCMA CAR-T cell therapy. Here, we report updated clinical data on GPRC5D CAR-T cell therapy in R/R MM pts who have progressed or developed refractory disease after anti-BCMA CAR-T therapy. **Methods:** This phase 2, single-arm study enrolled pts (18-70 years) with R/R MM. Eleven R/R MM pts with previous anti-BCMA CAR-T cell therapy were treated as part of the phase 2 study as previously reported. The primary endpoint was the proportion of pts who achieved an overall response. Safety was also assessed in eligible pts. **Results:** Eleven R/R MM pts with previous anti-BCMA CAR-T cell therapy were enrolled and underwent apheresis between November 25, 2021 and November 8, 2022. Median age was 63 (range 46-70) years and pts received a median of 5 (range 2-12) lines of therapy. Of 11 pts, 6 (55%) had extramedullary diseases, 6 (55%) had a high tumor burden, 4 (36%) had R-ISS stage III disease, and 4 (36%) had high-risk cytogenetic abnormalities. Median follow-up was 14.8 months (range 5.8-16.9). Eleven (100%) pts had an overall response, of whom 5 (45%) had a complete response (CR) or better. Two pts had received repeated anti-BCMA CAR-T cell infusions with no responses at the last time, of whom 1 patient achieved CR, and the other partial response after anti-GPRC5D CAR-T cell infusion. 8 (73%) of the 11 pts were minimal residual disease (MRD) negative in the bone marrow by multicolor flow cytometry (sensitivity: 10 -5). The median progression-free survival was 6.4 months (95% CI: 1.2 to 11.6 months). At the time of analysis, 5 (45%) pts are progression free and followed without additional therapy. We also noted robust GPRC5D-CAR expansion in the peripheral blood using qPCR with available data (peak expansion CAR DNA copies/μL, median: 22711; range: 2563- 75561). Grade 3 or higher hematological toxicities were neutropenia (10[91%]), anemia (7[64%]), and thrombocytopenia (6[55%]). Cytokine release syndrome occurred in 10 (91%) of 11 pts (all were grade 1 or 2); 5 (45%) pts received tocilizumab and 3 (27%) received dexamethasone for the management of CRS. No neurological

toxic effects were reported. One (9%) patient had a grade 1 nail change. One patient died of intracranial hemorrhage 29 days after CAR-T cell infusion, and no abnormal coagulation was observed. **Conclusions:** Our study demonstrates anti-GPRC5D CAR T-cell therapy are clinical active with a favorable safety profile in pts who do not respond to or relapse after anti-BCMA CAR T-cell therapy.

Combination of forimtamig with standard of care improves depth and duration of response in preclinical models of multiple myeloma

Jan Eckmann[1], Pablo Umana[2], Christian Klein[2], Tanja Fauti[2], Carina Hage[2], Stefanie Lechner[2], Bruno Paiva[3,4], Aintzane Zabaleta[3], Laura Blanco[3]

[1]Roche Innovation Center Munich, Penzberg, Germany; [2]Roche/Genentech; [3]Clínica Universidad de Navarra (CUN), Centro de Investigación Médica Aplicada (CIMA LAB Diagnostics), IDISNA; [4]CIBERONC

Introduction: Forimtamig (forimtamig) is a 2:1 GPRC5D T cell bispecific antibody with high clinical response rates of > 60% in relapsed or refractory multiple myeloma (MM) patients. **Methods:** Here, we highlight the therapeutic potential of combining forimtamig with standard of care (SoC) agents in MM using clinically relevant ex vivo and in vivo models of myeloma **Results:** We combined forimtamig with carfilzomib, daratumumab and/or pomalidomide in bone marrow aspirate samples from MM patients. Tumor lysis increased 2-fold from 40% to 80% when forimtamig was combined with daratumumab or with daratumumab and pomalidomide while combination with pomalidomide or carfilzomib showed no further increase in response. Antitumor effects were associated with increase of CD69 and PD-1 on CD8+ T cells and secretion of IFNg, MIP1a and granzyme A. Activation of CD8+ TILs was increased in combination with pomalidomide as shown by a 4-fold increased cytokine release and elevated surface expression of CD137 and CD25 compared to forimtamig alone. Forimtamig induced activation of NK cells, as measured by CD25 and CD107a expression which was increased 3-fold in combination with daratumumab and increased further for the triple combination with pomalidomide. A combination with carfilzomib did not change the activation status of autologous TILs or NK cells. Next, we explored any effect of SoC combinations on depth and durability of response in tumor-bearing humanized mice using a fixed duration schedule. Combination with pomalidomide resulted in faster onset of regressions in 20% of mice and increased tumor cell lysis (65% vs 45%) at the end of cycle 1 (C1). However, the progression free survival (PFS) rate of 53% achieved by forimtamig monotherapy at 3 weeks after last dosing was not improved overall. Although daratumumab combination had no impact on the depth of early responses, the PFS rate increased by 10%. carfilzomib induced rapid onset of regressions in 70% of mice in C1 and showed the highest PFS rate of 70%. To test potential effects of SoC combinations on cytokine release syndrome (CRS), we measured cytokine levels in serum of mice 48h after treatment initiation. In line with our ex vivo results, pomalidomide combination further increased serum levels of IFNg, IL2 and TNFa compared to forimtamig alone while daratumumab induced only a moderate increase of TNFa. In contrast, we observed a slight decrease in cytokine release in combination with carfilzomib. **Conclusions:** Synergistic anti-tumoral and NK stimulatory effects suggest a benefit of daratumumab combination in patients with high tumor burden and high risk of developing CRS. Broad immunomodulatory effects of pomalidomide could help sustain T cell responses in patients but may increase the risk of CRS. Considering the importance of balancing CRS and efficacy, carfilzomib was identified as another promising combination partner for forimtamig.

Introduction: Bone destruction is a common complication in multiple myeloma. Radiological bone disease at diagnosis is present in 79% of multiple myeloma (MM) patients and 59% experience bone pain. Even more patients will experience bone complications at some time point in their course of disease. Progression of bone disease can be inhibited by treating MM patients with Zoledronic acid (ZOL). ZOL has been shown to increase quality of life and overall survival in myeloma patients, however ZOL is also associated to osteonecrosis of the jaw (BON). BON is a debilitating condition where maxillary and/or mandibular bone necrotize, often with infection. The risk of BON increases with potency and length of treatment with bisphosphonates. BON can be triggered by tooth extraction and a number of precautions have been suggested including treating tooth problems before initiating ZOL, to pause ZOL treatment before procedures, and to give prophylactic perioperative antibiotics at procedures. The optimal length of treatment with ZOL is yet uncertain, as evidence is limited. The original bisphosphonate studies followed myeloma patients for 21 and 24 months, respectively, and considering possible increased risk of BON most guidelines currently recommends two years treatment. As the average lifetime of myeloma patients increase, the question arises whether longer treatment is better for optimal protection

toxic effects were reported. One (9%) patient had a grade 1 nail change. One patient died of intracranial hemorrhage 29 days after CAR-T cell infusion, and no abnormal coagulation was observed. **Conclusions:** Our study demonstrates anti-GPRC5D CAR T-cell therapy are clinical active with a favorable safety profile in pts who do not respond to or relapse after anti-BCMA CAR T-cell therapy.

Introduction: Bone destruction is a common complication in multiple myeloma. Radiological bone disease at diagnosis is present in 79% of multiple myeloma (MM) patients and 59% experience bone pain. Even more patients will experience bone complications at some time point in their course of disease. Progression of bone disease can be inhibited by treating MM patients with Zoledronic acid (ZOL). ZOL has been shown to increase quality of life and overall survival in myeloma patients, however ZOL is also associated to osteonecrosis of the jaw (BON). BON is a debilitating condition where maxillary and/or mandibular bone necrotize, often with infection. The risk of BON increases with potency and length of treatment with bisphosphonates. BON can be triggered by tooth extraction and a number of precautions have been suggested including treating tooth problems before initiating ZOL, to pause ZOL treatment before procedures, and to give prophylactic perioperative antibiotics at procedures. The optimal length of treatment with ZOL is yet uncertain, as evidence is limited. The original bisphosphonate studies followed myeloma patients for 21 and 24 months, respectively, and considering possible increased risk of BON most guidelines currently recommends two years treatment. As the average lifetime of myeloma patients increase, the question arises whether longer treatment is better for optimal protection

of progressive bone disease, and if this can be achieved without unacceptable high risk of BON. **Methods:** Patients with newly diagnosed symptomatic MM were included and randomized after 2 years ZOL treatment to either two additional years of monthly IV ZOL treatment or observation. Patients with progressive bone disease (PBD) just prior to randomization did not proceed to randomization but remained on ZOL treatment. Patients were followed with monthly visits and blood samples. Bone imaging by low-dose whole body CT was performed every 6 months and quality of life questionnaire data were sampled every 3 months. Moreover, bone imaging was performed when clinically indicated. Criteria for PBD were ≥25% increase in size of existing osteolytic lesions or new osteolytic lesions (both at least 10 mm increase/diameter), new fractures, or lesions needing irradiation therapy or surgery. **Results:** A total of 192 patients with myeloma were randomized, median follow up after randomization was 21.6 months. In total, 8 cases of PBD were found in the ZOL arm and 18 cases were found in the observational arm. Risk of PBD was significantly lower in the ZOL arm (hazard ratio: 0.38, 95% CI (0.17-0.88), p = 0.024). The incidence of BON after 2 years was 3.6% and not different between the two groups. We found no difference in overall survival between the ZOL arm and the observational arm **Conclusions:** Four years of monthly zoledronic acid are superior to two years treatment in protection against progressive bone disease in multiple myeloma.

Utility of 18FDG-PET/CT for risk prediction in relapsed/refractory multiple myeloma patients undergoing CAR-T cell therapy: analysis of baseline and early assessment scans after one and three months

Luis-Esteban Tamariz-Amador[1], Ana Alfonso-Pierola[1], Sofia Huerga-Dominguez[1], Maria Panizo-Inoges[1], Maria-Luisa Palacios-Berraquero[2], Sara Villar[1], Maria Marcos-Jubilar[1], Victoria Betech-Antar[1], Evelyn Valencia-Espinoza[1], Jose Rifon[1], Felipe Prosper[1], Jesús San-Miguel[3], Maria-Jose Garcia-Velloso[1], Paula Rodríguez-Otero[1]

[1]Clinica Universidad de Navarra, Centro de Investigacion Medica Aplicada (CIMA), IdiSNA; [2]Hospital Universitario Ramon y Cajal; [3]Cancer Center Clinica Universidad de Navarra, Centro Investigacion Medica Aplicada, Instituto de Investigacion de Navarra, Centro Investigacion Biomedica en Red Cancer, Pamplona, Spain

Introduction: Chimeric antigen receptor (CAR) T-cells are an effective treatment for relapsed/refractory multiple myeloma (RRMM) patients. Unfortunately, a significant number relapse during the first two years. The predictive value of positron emission tomography/computed tomography (18FDG-PET/CT) in this group of patients has not been established. Our aim is to assess the utility of 18FDG-PET/CT for risk prediction in RRMM patients undergoing CAR-T cell therapy. **Methods:** Sixty-two patients received CAR-T cell therapy between April 2018 and February 2023. 18FDG-PET/CT was performed at baseline for all patients, and 1 and 3 months after infusion for 57 (92%) and 51 (82%) patients, respectively. We analyzed the presence of focal lesions (FL), paramedullary (PMD), and extramedullary disease (EMD); bone marrow (BM) and FL uptake measured by Deauville score. 18FDG-PET/CT was positive if Deauville scores ≥4 was found for any of the previous variables. **Results:** Out of 62 baseline exams, 49 (79%) were positive. At baseline the presence of hypermetabolic EMD was the only variable associated with worse progression-free (PFS) (hazard ratio [HR] 4.8 [95%CI 2.0 – 11.3; P < .001]) and overall survival (OS) (HR 2.9 [95%CI 1.2 – 6.8; P = .018]). In terms of response evaluation, 33 out of 57 (58%) and 18 out of 51 (35%) scans were positive 1 and 3 months after infusion, respectively. A negative scan at 3 months was associated with improved PFS (median 16 months [95%CI 12 – 19] vs. 6.8 [95%CI 3.4 – 10.3]; P = .04) and OS (median 34 months [95%CI 16 – 52]; vs. 11 [95%CI 7.6 – 15]; P = .012). Interestingly, the assessment at month 1 did not detect any differences in PFS (P = .28), although it did reveal statistically significant differences in OS (median 34 vs. 13 months; P = .021). The presence of hypermetabolic FL with Deauville = 4 did not significantly impact PFS when compared to FL with a Deauville ≤ 3 at both month 1 (median NR vs. 14.5 months; P = 0.23) and 3 (median 18 vs. 8.1 months; P = 0.33). Furthermore, the persistence of hypermetabolic EMD at 3 months was associated with shorter PFS (HR 18.2 [95%CI 5.0 – 65.9]; P < .001) and OS (HR 5.7 [95%CI 1.8 – 18.4; P = .003]). Conversely to basal scans, persistent hypermetabolic PMD at month 3 was associated with shorter PFS (median 3.7 months [95%CI 3.6 – 3.9] vs. 14.5 [95%CI 9.0 – 19.9]; P < .001) (HR 6.2 [95%CI 1.9 – 21.1]; P = .002) and OS (median 7.8 months [95%CI 3.4 – 12.2] vs. 34.2 [95%CI 19.9 – 45.6]; P < .001) (HR 8.3 [95%CI 2.5 – 27.6]; P = .001). **Conclusions:** In conclusion, our study suggests that 18FDG-PET/CT is a valuable tool for staging and prognostication in patients with RRMM treated with CAR-T cells. Based on our results, the optimal timing for response assessment is 3 months after infusion and the persistence of FL uptake with Deauville score = 4 should be evaluated with caution along with other exams.

of progressive bone disease, and if this can be achieved without unacceptable high risk of BON. **Methods:** Patients with newly diagnosed symptomatic MM were included and randomized after 2 years ZOL treatment to either two additional years of monthly IV ZOL treatment or observation. Patients with progressive bone disease (PBD) just prior to randomization did not proceed to randomization but remained on ZOL treatment. Patients were followed with monthly visits and blood samples. Bone imaging by low-dose whole body CT was performed every 6 months and quality of life questionnaire data were sampled every 3 months. Moreover, bone imaging was performed when clinically indicated. Criteria for PBD were ≥25% increase in size of existing osteolytic lesions or new osteolytic lesions (both at least 10 mm increase/diameter), new fractures, or lesions needing irradiation therapy or surgery. **Results:** A total of 192 patients with myeloma were randomized, median follow up after randomization was 21.6 months. In total, 8 cases of PBD were found in the ZOL arm and 18 cases were found in the observational arm. Risk of PBD was significantly lower in the ZOL arm (hazard ratio: 0.38, 95% CI (0.17-0.88), p = 0.024). The incidence of BON after 2 years was 3.6% and not different between the two groups. We found no difference in overall survival between the ZOL arm and the observational arm **Conclusions:** Four years of monthly zoledronic acid are superior to two years treatment in protection against progressive bone disease in multiple myeloma.

Introduction: Chimeric antigen receptor (CAR) T-cells are an effective treatment for relapsed/refractory multiple myeloma (RRMM) patients. Unfortunately, a significant number relapse during the first two years. The predictive value of positron emission tomography/computed tomography (18FDG-PET/CT) in this group of patients has not been established. Our aim is to assess the utility of 18FDG-PET/CT for risk prediction in RRMM patients undergoing CAR-T cell therapy. **Methods:** Sixty-two patients received CAR-T cell therapy between April 2018 and February 2023. 18FDG-PET/CT was performed at baseline for all patients, and 1 and 3 months after infusion for 57 (92%) and 51 (82%) patients, respectively. We analyzed the presence of focal lesions (FL), paramedullary (PMD), and extramedullary disease (EMD); bone marrow (BM) and FL uptake measured by Deauville score. 18FDG-PET/CT was positive if Deauville scores ≥4 was found for any of the previous variables. **Results:** Out of 62 baseline exams, 49 (79%) were positive. At baseline the presence of hypermetabolic EMD was the only variable associated with worse progression-free (PFS) (hazard ratio [HR] 4.8 [95%CI 2.0 – 11.3; P < .001]) and overall survival (OS) (HR 2.9 [95%CI 1.2 – 6.8; P = .018]). In terms of response evaluation, 33 out of 57 (58%) and 18 out of 51 (35%) scans were positive 1 and 3 months after infusion, respectively. A negative scan at 3 months was associated with improved PFS (median 16 months [95%CI 12 – 19] vs. 6.8 [95%CI 3.4 – 10.3]; P = .04) and OS (median 34 months [95%CI 16 – 52]; vs. 11 [95%CI 7.6 – 15]; P = .012). Interestingly, the assessment at month 1 did not detect any differences in PFS (P = .28), although it did reveal statistically significant differences in OS (median 34 vs. 13 months; P = .021). The presence of hypermetabolic FL with Deauville = 4 did not significantly impact PFS when compared to FL with a Deauville ≤ 3 at both month 1 (median NR vs. 14.5 months; P = 0.23) and 3 (median 18 vs. 8.1 months; P = 0.33). Furthermore, the persistence of hypermetabolic EMD at 3 months was associated with shorter PFS (HR 18.2 [95%CI 5.0 – 65.9]; P < .001) and OS (HR 5.7 [95%CI 1.8 – 18.4; P = .003]). Conversely to basal scans, persistent hypermetabolic PMD at month 3 was associated with shorter PFS (median 3.7 months [95%CI 3.6 – 3.9] vs. 14.5 [95%CI 9.0 – 19.9]; P < .001) (HR 6.2 [95%CI 1.9 – 21.1]; P = .002) and OS (median 7.8 months [95%CI 3.4 – 12.2] vs. 34.2 [95%CI 19.9 – 45.6]; P < .001) (HR 8.3 [95%CI 2.5 – 27.6]; P = .001). **Conclusions:** In conclusion, our study suggests that 18FDG-PET/CT is a valuable tool for staging and prognostication in patients with RRMM treated with CAR-T cells. Based on our results, the optimal timing for response assessment is 3 months after infusion and the persistence of FL uptake with Deauville score = 4 should be evaluated with caution along with other exams.

Introduction: The role of sustained MRD negativity as a biomarker to stop treatment is being investigated in transplant-eligible MM. Thus, it is important to identify risk-factors of MRD resurgence and/or progressive disease (PD) among patients achieving undetectable MRD to avoid undertreating them. **Methods:** Transplant-eligible MM patients enrolled in the GEM2012MENOS65/GEM2014MAIN clinical trials who achieved MRD negativity by NGF (limit of detection, 2x10-6) were analyzed. A multivariate Fine-Gray statistical model was applied to the dataset, subsequently fitting a weighted Cox model to assess the cumulative incidence of MRD resurgence and/or PD. Death without PD was considered a competing event. **Results:** A total of 267/458 (58%) patients achieved MRD negativity by NGF after induction (n=125), HDT/ASCT (n=77), consolidation (n=32) or after the first year of maintenance therapy (n=33) and were eligible for the analysis. After a median follow-up of 73 months since the first MRD negative assessment, 145/267 (54%) patients remained progression-free and had sustained MRD negativity until last time to follow up, while 111/267 (42%) patients had MRD resurgence (n=71) and/or PD (n=40), and 11/267 (4%) patients died without PD. The overall cumulative incidence of an MRD resurgence and/or PD event at 73 months was 44%. Time from achievement of first MRD negativity until MRD resurgence was similar in patients with or without subsequent disease progression (21 [8-34] and 25 [13-47] months, respectively, P=.188). The median PFS since MRD resurgence until PD or death was 39 months. The only prognostic factors at diagnosis that predicted MRD resurgence and/or PD were an International staging system (ISS) 3 and ≥0.01% CTCs. LDH levels and the R-ISS were not significantly associated, while a high-risk cytogenetic status tended towards significance. Treatment randomization with Bu-Mel or Mel-200 HDT in the GEM2012MENOS65 trial, and with IRD vs RD in the GEM2014MAIN trial also had no impact. Patients who achieved MRD negativity after induction (< 6 months) had significantly lower risk of MRD resurgence and/or PD than those who achieved MRD negativity at a later time point. Because of the potential complementarity provided by patients' ISS, CTC levels (≥0.01%) and the time to achievement of first MRD negative assessment, the three risk factors were modeled for a more accurate prediction of MRD resurgence and/or PD. Accordingly, patients having none versus one versus two or more risk factors showed 5-year rates of MRD resurgence and/or PD of 16%, 33% and 57%, respectively (P<.001). **Conclusions:** We present a dynamic model to predict the risk of MRD resurgence and/or PD after MRD negativity. This dynamic model relies on three easily measurable risk factors. The insights it offers can prove valuable in the careful selection of transplant-eligible MM patients for whom treatment cessation due to MRD negativity is being investigated in clinical trials or its implementation is being considered in routine practice.

Introduction: Circulating tumor cells (CTCs) have shown an independent prognostic value in transplant-eligible (TE) patients (pts) with newly diagnosed multiple myeloma (NDMM). In this study, we aimed to evaluate the optimal clinical CTC cut-off for both TE and transplant ineligible (TI) NDMM pts, using the high-sensitive next generation flow-cytometry (NGF). Moreover, we performed matched analysis of both bone marrow (BM) and peripheral blood (PB) to highlight any possible inconsistencies between the two sites. **Methods:** We studied 550 NDMM pts; 210 (38%) were TE and 340 (62%) were TI. NGF was used for the detection of clonal cells in both BM and PB. To define the optimal clinical cut-off of CTCs, we performed various multivariable regression models including CTCs, ISS (or R-ISS), cytogenetic status and LDH, and selected the one with the best performance. The median follow-up period was 41 months (range: 5-66 months). The BM niche profiling was examined with mass cytometry (CyTOF, n=15 pts) and various multicolor flow cytometry panels (n=199

The median follow-up period was 41 months (range: 5-66 months). The BM niche profiling was examined with mass cytometry (CyTOF, n=15 pts) and various multicolor flow cytometry panels (n=199

pts) that allowed the detection of 32 distinct immune populations. **Results:** CTCs were detected in 493/550 (89.6%) pts with a median value of 0.01% of all nucleated cells. Increased levels of CTCs correlated with advanced ISS stage (0.002%, 0.007% and 0.037% for pts with ISS-I, ISS-II and ISS-III respectively, p< 0.0001), high risk cytogenetics (median: 0.038% vs. 0.006% in standard risk, p< 0.0001), and higher levels of b2-microglobulin and BM infiltration. Pts with phenotypic inconsistencies between BM and PB had higher levels of CTCs and more often a diffuse MRI pattern than those with a phenotypic agreement (40% vs.10%, p< 0.01). The optimal clinical cut-off of CTCs was defined at 0.02%, stratifying pts in two different prognostic groups with high and low CTCs [median PFS: 40 months vs. not reached (NR), HR: 2.59, 95% CI:1.71-3.91, p< 0.0001]. In the multivariable analysis the 0.02% cut-off was independent from ISS and/or cytogenetics and was clinically relevant for both TI (median PFS: 47 vs. 23 months, p< 0.0001) and TE pts (median PFS: NR in both categories, p< 0.01). The 2-year probability of MRD negativity was 45% and 67% for pts with high and low CTCs; median time to MRD negativity was 34 vs. 17 months, respectively (HR:1.7, 95% CI:1.2-2.4, p=0.002). Of note, pts with high CTCs who achieved MRD negativity, modulated their unfavorable risk status and showed a similar PFS with those who had low CTCs. Beyond prognostication, pts with high CTC levels showed unique BM immune profiles characterized by increased levels of T cells, NK cells, TAMs and an increased memory/naive B cell ratio. **Conclusions:** The presence of CTC at a level of >0.02% confers an adverse prognostic factor for NDMM pts, irrespective of their transplant status. Since the liquid biopsy is a better representative of the entire tumor load than a tissue biopsy sample, the analysis of CTCs may serve as the new hallmark for the real-time evaluation of a patient's disease and immune status.

Persistent bone marrow and imaging MRD negativity may guide the duration of lenalidomide maintenance following ASCT in patients with multiple myeloma

Panagiotis Malandrakis[1], Ioannis Ntanasis-Stathopoulos[1], Ioannis Kostopoulos[1], Maria Gavriatopoulou[1], Foteini Theodorakakou[1], Despina Fotiou[1], Magdalini Migkou[1], Maria Roussou[1], Vassiliki Spiliopoulou[1], Evangelos Eleutherakis-Papaiakovou[1], Efstathios Kastritis[1], Ourania Tsitsilonis[1], Meletios Dimopoulos[1], Evangelos Terpos[1]

Introduction: Autologous stem cell transplantation (ASCT) and lenalidomide maintenance is the standard of care for eligible patients with newly diagnosed multiple myeloma (MM). Sustained marrow and imaging minimal residual disease (MRD) correlate with prolonged progression-free (PFS) and overall survival (OS). It is essential to define the optimal duration of maintenance and reveal criteria to discontinue maintenance. **Methods:** We prospectively included patients with newly diagnosed MM from 1/1/2016 to 31/12/2019. MRD (Euroflow) was assessed in patients with stringent complete remission (sCR) and then at 6, 12, 24, and 36 months after the initiation of lenalidomide maintenance. Patients with at least 3 consecutive MRD negative results and after 36 months of maintenance underwent PET/CT. If patients had achieved imaging MRD negativity, they discontinued lenalidomide maintenance and MRD was performed every 6 months thereafter. If a patient converted from MRD negative to positive or if the patient relapsed from sCR, lenalidomide maintenance was restarted. **Results:** Overall, 151 patients received induction with proteasome inhibitor-based regimens (VCD, VRD) and underwent ASCT. During a median follow-up of 70 months (range 6-84 months) from the time of ASCT, 44 (29.1%) patients had disease progression and 20 (13.2%) patients died. Out of 107 patients who did not progress or die, 42 (39.2%) patients achieved sustained bone marrow MRD negativity and imaging MRD negativity at 3 years after maintenance initiation. Thus, they discontinued lenalidomide maintenance. Their median age at MM diagnosis was 56 years (range 43-66). Twenty-one (50%) patients were males, whereas 52.4% had IgG, 26.2% had IgA and 21.4% had light chain MM. The patient distribution per ISS was ISS 1 63.4%, ISS 2 19.5% and ISS 3 17.1%, whereas per R-ISS was RISS-1 57.5%, RISS-2 35% and RISS-3 7.5%. The median follow up time from maintenance discontinuation for all patients was 16 months (range 1-31). Six months after discontinuation of lenalidomide maintenance, 39 out of 41 patients were found to be MRD negative. At 12 months post-lenalidomide discontinuation, 36 out of 38 patients continued to be MRD negative. At 18 months, all evaluable patients (n=18) remained MRD negative. At 24 months, 13 out of 14 patients were MRD negative and at 30 months all 4 evaluable patients were MRD negative. Overall, five patients restarted treatment with lenalidomide monotherapy after converting from MRD negative to MRD positive following the initial completion of maintenance. One patient progressed and received second line of treatment. Only one patient who discontinued maintenance died for reasons not related to multiple myeloma, and with no symptoms of disease progression. **Conclusions:** Sustained MRD negativity after 3 years lenalidomide maintenance may guide the safe discontinuation of maintenance, although this has to be proven in prospective randomized clinical trials.

Serial MRD assessments as a surrogate for long term progression free survival

Nishanth Thalambedu[1], Phillip Farmer[1], Robert Smith[1], Daisy Alapat[1], Carolina Schinke[1], Sharmilan Thanendrarajan[1], John Shaughnessy[1], Fenghuang Zhan[1], Maurizio Zangari[1], Samer Al Hadidi[1], Frits van Rhee[1]

[1]University of Arkansas for Medical Sciences

Introduction: The introduction of novel agents in myeloma together with high dose chemotherapy has made it possible to strive for an operational cure at least in a proportion of patients. However, this requires long-term follow-up, which is outside the scope of many clinical trials. MRD negativity has been associated

with a deeper response and better progression free survival (PFS). Herein, we examine whether serial MRD measurements in the first 5 years after diagnosis can serve as a surrogate for long-term outcome. **Methods:** 1744 patients received a single or tandem autologous stem cell transplant for newly diagnosed myeloma. Standard demographic variables were collected. Bone marrow examinations were performed every 6-12 months and subjected to 8-color flow cytometry with a sensitivity of 10-5. All patients had at least 3 serial MRD tests performed in the first 5 years. Patients were allocated to three groups: Group 1 patients (n=487) had 3 serial MRD negative tests in the first 5 years and remained MRD negative. Group 2 patients (n=872) had both negative and positive MRD tests. Group 3 patients (n=385) were always MRD positive at every test. PFS was calculated using the Kaplan-Meier method from the date of first autologous stem cell transplant (ASCT) and compared with the log-rank test. The study was approved by the institutional IRB. **Results:** The median age was 62.7 (range 29.4-85.9); 716 were >65 years. There were 303 (25.7%), 721 (61.0%) and 157 (13.3%) patients with R-ISS stage, R-ISS stage 2 and R-ISS stage 3 respectively. An elevated LDH (>190) was present in 410/1739 (23.6%). Abnormal cytogenetics were present in 410/1739 (50.6%). 1744 patients received one ASCT and 945 two ASCT (54.2%). High risk GEP was present in 209/1190 (17.6%). Overall, the median follow-up was 4.4 years (range: 0.1-17.3) Group 1 and Group 2 patients had a similar median MRD tests performed in the first 5 years post ASCT: 10 (range 3-24) and 9 (range 3-23) respectively. Group 3 had a lower median MRD test due to more early relapses (7:range 3-29) A similar observation applied to the total number of MRD test performed in each group; Group 1 median 11 tests (range 3-31), Group 2 median 12 tests (range 3-35), and Group 3 median 7 tests (range 3-29). The PFS at 5 years landmarked from first ASCT for group 1,2 and 3 were respectively 90, 48 and 8%.The PFS at 10 years were respectively 74, 30 and 1%. These differences were highly statistically different (P< 0.001). Group 3 were more likely to be older (p-value< 0.001), have baseline ISS and RISS stage III disease (p-value< 0.001 and 0.045), have abnormal cytogenetics profile (p-value< 0.001), abnormal FLC (p-value< 0.001) and have a high-risk GEP profile (p-value=0.0319) compared to Group 2 patients. **Conclusions:** Achievement of 3 serial MRD negative tests in the first 5 years of therapy is predictive of an excellent long-term outcome with few treatment failures.

The rs9344 G risk allele upregulates CCND1 expression through t(11;14) and PAX5 in multiple myeloma

Introduction: Multiple myeloma (MM) is an incurable plasma cell malignancy characterized by recurrent primary cytogenetic abnormalities such as t(11;14)(q13;q32), resulting in upregulation of CCND1. While the G allele of rs9344 (c.723G>A, p.Pro241) in exon 4 of the CCND1 gene is the most significant susceptibility allele for t(11;14) by GWAS, the mechanism of how rs9344 contributes to MM remains unknown. **Methods:** We studied 1,359 patients with MM including two independent and ancestrally diverse cohorts (CoMMpass and Tempus). We analyzed whole exome and RNA-seq data and performed a multivariate generalized linear model (GLM). We also analyzed ATAC-seq and ChIP-seq data of the GM12878 normal lymphoblastoid cell line (heterozygous for rs9344 G/A) and MM patient samples. The t(11;14)+ U266 and KMS12 PE cell lines were used for biological confirmation. QRT-PCR was used to assess the expression of CCND1 in U266 cells before and after PAX5 knockdown (KD) with siRNAs and KMS12 PE engineered cell lines with G>A substitution at rs9344. P-values < 0.05 (two-side) were considered statistically significant. **Results:** The rs9344 G risk allele was associated with t(11;14) MM (OR=1.88, P-value =3.2x10-5 in CoMMpass and OR=1.54, P-value =0.002 in Tempus cohorts). In cells heterozygous for rs9344 (A/G), the G allele occurred in cis with the t(11;14) in 80.34% (95%CI: 64.92–98.32%) of cases demonstrating a biological preference for the G allele in t(11;14). Among t(11;14) cases, the G allele was associated with a significant increase of H3K27ac, H3K4me3, H3K4me1 and chromatin accessibility (P-value=9.2 x10-3-7.3 x10-16) demonstrating an allele-specific regulatory role for rs9344 within the CCND1 locus. Further, using ENCODE ChIP-seq data from the GM12878 cell line, we identified a PAX5 binding site within CCND1, with the binding motif being one base-pair centromeric to rs9344. The G allele was associated with increased PAX5 signal relative to the A allele (P-value =1.09E-01). We reason that the increased binding of PAX5 to the G allele contributed to increased expression of CCND1. This was supported by the observations of the increased PAX5 expression in t(11;14) relative to non-t(11;14) MM patient samples, and the increased CCND1 expression within the t(11;14) subgroup with the G allele: 21.98% (95%CI:18.06-25.8%, P-value =1.3 x 10-26) in CoMMpass and 14.48% (95%CI:9.32-19.64%, P-value =5.2 x 10-8) in Tempus. PAX5 KD in U266 cells resulted in a reduction in CCND1 expression and conversion of AA to GG using CRISPR/Cas9 in KMS12 PE cells was associated with an increase in CCND1 expression, confirming the associations of t(11;14) with rs9344 (P-value ≤ 0.002) and with CCND1 (P-value ≤ 1.2x10-143). **Conclusions:** We demonstrate a novel enhancer involving rs9344 and its interaction with PAX5 together with t(11;14) accounting for 98% (95%CI:86.51–100%) of CCND1 expression. Future studies will explore how this association contributes to increased risk of t(11;14) MM.

The PFS at 5 years landmarked from first ASCT for group 1,2 and 3 were respectively 90, 48 and 8%.The PFS at 10 years were respectively 74, 30 and 1%. These differences were highly statistically different (P< 0.001). Group 3 were more likely to be older (p-value< 0.001), have baseline ISS and RISS stage III disease (p-value< 0.001 and 0.045), have abnormal cytogenetics profile (p-value< 0.001), abnormal FLC (p-value< 0.001) and have a high-risk GEP profile (p-value=0.0319) compared to Group 2 patients. **Conclusions:** Achievement of 3 serial MRD negative tests in the first 5 years of therapy is predictive of an excellent long-term outcome with few treatment failures.

Introduction: Multiple myeloma (MM) is an incurable plasma cell malignancy characterized by recurrent primary cytogenetic abnormalities such as t(11;14)(q13;q32), resulting in upregulation of CCND1. While the G allele of rs9344 (c.723G>A, p.Pro241) in exon 4 of the CCND1 gene is the most significant susceptibility allele for t(11;14) by GWAS, the mechanism of how rs9344 contributes to MM remains unknown. **Methods:** We studied 1,359 patients with MM including two independent and ancestrally diverse cohorts (CoMMpass and Tempus). We analyzed whole exome and RNA-seq data and performed a multivariate generalized linear model (GLM). We also analyzed ATAC-seq and ChIP-seq data of the GM12878 normal lymphoblastoid cell line (heterozygous for rs9344 G/A) and MM patient samples. The t(11;14)+ U266 and KMS12 PE cell lines were used for biological confirmation. QRT-PCR was used to assess the expression of CCND1 in U266 cells before and after PAX5 knockdown (KD) with siRNAs and KMS12 PE engineered cell lines with G>A substitution at rs9344. P-values < 0.05 (two-side) were considered statistically significant. **Results:** The rs9344 G risk allele was associated with t(11;14) MM (OR=1.88, P-value =3.2x10-5 in CoMMpass and OR=1.54, P-value =0.002 in Tempus cohorts). In cells heterozygous for rs9344 (A/G), the G allele occurred in cis with the t(11;14) in 80.34% (95%CI: 64.92–98.32%) of cases demonstrating a biological preference for the G allele in t(11;14). Among t(11;14) cases, the G allele was associated with a significant increase of H3K27ac, H3K4me3, H3K4me1 and chromatin accessibility (P-value=9.2 x10-3-7.3 x10-16) demonstrating an allele-specific regulatory role for rs9344 within the CCND1 locus. Further, using ENCODE ChIP-seq data from the GM12878 cell line, we identified a PAX5 binding site within CCND1, with the binding motif being one base-pair centromeric to rs9344. The G allele was associated with increased PAX5 signal relative to the A allele (P-value =1.09E-01). We reason that the increased binding of PAX5 to the G allele contributed to increased expression of CCND1. This was supported by the observations of the increased PAX5 expression in t(11;14) relative to non-t(11;14) MM patient samples, and the increased CCND1 expression within the t(11;14) subgroup with the G allele: 21.98% (95%CI:18.06-25.8%, P-value =1.3 x 10-26) in CoMMpass and 14.48% (95%CI:9.32-19.64%, P-value =5.2 x 10-8) in Tempus. PAX5 KD in U266 cells resulted in a reduction in CCND1 expression and conversion of AA to GG using CRISPR/Cas9 in KMS12 PE cells was associated with an increase in CCND1 expression, confirming the associations of t(11;14) with rs9344 (P-value ≤ 0.002) and with CCND1 (P-value ≤ 1.2x10-143). **Conclusions:** We demonstrate a novel enhancer involving rs9344 and its interaction with PAX5 together with t(11;14) accounting for 98% (95%CI:86.51–100%) of CCND1 expression. Future studies will explore how this association contributes to increased risk of t(11;14) MM.

with a deeper response and better progression free survival (PFS). Herein, we examine whether serial MRD measurements in the first 5 years after diagnosis can serve as a surrogate for long-term outcome. **Methods:** 1744 patients received a single or tandem autologous stem cell transplant for newly diagnosed myeloma. Standard demographic variables were collected. Bone marrow examinations were performed every 6-12 months and subjected to 8-color flow cytometry with a sensitivity of 10-5. All patients had at least 3 serial MRD tests performed in the first 5 years. Patients were allocated to three groups: Group 1 patients (n=487) had 3 serial MRD negative tests in the first 5 years and remained MRD negative. Group 2 patients (n=872) had both negative and positive MRD tests. Group 3 patients (n=385) were always MRD positive at every test. PFS was calculated using the Kaplan-Meier method from the date of first autologous stem cell transplant (ASCT) and compared with the log-rank test. The study was approved by the institutional IRB. **Results:** The median age was 62.7 (range 29.4-85.9); 716 were >65 years. There were 303 (25.7%), 721 (61.0%) and 157 (13.3%) patients with R-ISS stage, R-ISS stage 2 and R-ISS stage 3 respectively. An elevated LDH (>190) was present in 410/1739 (23.6%). Abnormal cytogenetics were present in 410/1739 (50.6%). 1744 patients received one ASCT and 945 two ASCT (54.2%). High risk GEP was present in 209/1190 (17.6%). Overall, the median follow-up was 4.4 years (range: 0.1-17.3) Group 1 and Group 2 patients had a similar median MRD tests performed in the first 5 years post ASCT: 10 (range 3-24) and 9 (range 3-23) respectively. Group 3 had a lower median MRD test due to more early relapses (7:range 3-29) A similar observation applied to the total number of MRD test performed in each group; Group 1 median 11 tests (range 3-31), Group 2 median 12 tests (range 3-35), and Group 3 median 7 tests (range 3-29). The PFS at 5 years landmarked from first ASCT for group 1,2 and 3 were respectively 90, 48 and 8%.The PFS at 10 years were respectively 74, 30 and 1%. These differences were highly statistically different (P< 0.001). Group 3 were more likely to be older (p-value< 0.001), have baseline ISS and RISS stage III disease (p-value< 0.001 and 0.045), have abnormal cytogenetics profile (p-value< 0.001), abnormal FLC (p-value< 0.001) and have a high-risk GEP profile (p-value=0.0319) compared to Group 2 patients. **Conclusions:** Achievement of 3 serial MRD negative tests in the first 5 years of therapy is predictive of an excellent long-term outcome with few treatment failures.

Introduction: Hyperdiploidy (HRD) and immunoglobulin translocations (IGH) are historically considered initiating genomic events in MM pathogenesis, often acquired decades prior the diagnosis. **Methods:** To investigate the existence of genomic events acquired before known MM initiating events we interrogated WGS data from 323 patients with newly diagnosed MM (NDMM). CoMMpass WGS were included as validation (n=752 NDMM). Our analytical and chronological workflow was developed by integrating single nucleotide variants (SNV), structural variants (SV) and copy number variants (CNV) comprising two main steps. First, we estimated molecular time (i.e. corrected ratio between duplicated and non-duplicated clonal SNV) of large and clonal chromosomal duplications and identified the earliest set of chromosomal gains in each patient. Second, within each early large chromosomal gain we identified clonal SV mediating CNV loss. A deletion on a gain can generate three possible scenarios: 1) one of the duplicated alleles is lost after the gain (i.e. post-gain) causing a CNV jump from 3:1 to 2:1 (total alleles:minor alleles); 2) there is a deletion before the duplication (i.e., pre-gain) causing a CNV jump from 3:1 to 1:0. 3) the deletion occurs on the minor, non-duplicated allele, causing a CNV jump from 3:1 to 2:0. Timing the deletion in relation with the chromosomal duplication is impossible in this scenario. **Results:** Molecular time data were generated for 257 patients, 65.8% of which were HRD without IGH translocations. Pre-gain deletions acquired before the earliest multi-chromosomal gain events were detected in 22 patients (8.7%). Post-gain deletions were observed in 88 patients (34.2%). Pre-gain events tended to involve more tumor suppressor genes (TSG) such as TCF3, ATM and TRAF3. While post gain events often occurred near oncogenes such as PIK3CA, KLHL6, and BCL10. Surprisingly, one patient exhibited a pre-gain ATM/BIRC3 deletion on a 11q gain caused by a t(11;14)(CCND1;IGH). Because the gain and translocation occurred simultaneously, the deletion occurred before both events. This is the first evidence of a driver event prior to an early IGH translocation. As validation, we investigated the MMRF CoMMpass study (n=752). Because of the low coverage not allowing for molecular time estimation, we limited our analysis to HRD without IGH translocation. Pre-gain and post-gain deletions were observed in 10.1% (44/434) and 64.1% (278/434) of patients, respectively. Combined WGS/RNAseq analysis showed pre-gain deletions inducing loss of function in TSG such as TRAF3, RAD51B, and DNMT3A. In contrast post-gain deletions induced a more heterogenous impact with loss of function in TSG and gain of function of oncodrivers such as BCL6 and USP6. **Conclusions:** Thanks to the development of a new WGS-based chronological model, we revealed, for the first time, the existence of SV acquired before canonical initiating events in newly diagnosed MM patients.

Identification of therapy-induced clonal evolution and resistance pathways in MRD clones in multiple myeloma through single-cell sequencing

Jian Cui[1], Xiaoyun Li[1,2], Shuhui Deng[1,2], Xin Gao[1,2], Lugui Qiu[1,2], Gang An[1,2]

[1]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College; [2]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem,

Introduction: In multiple myeloma (MM), the leading cause of disease progression, exhibits intratumoral heterogeneity that enables adaptability, limits therapeutic success, and remains incompletely understood. Previous studies have confirmed that clonal evolution frequently occurs at disease follow-up, and the patterns of clonal evolution between diagnosis and relapse correlates with patient outcomes. However, it remains unclear whether clonal evolution occurs as early as after induction therapy. Additionally, the mechanisms of malignant plasma cells (PCs) resistance after induction therapy have only been partly resolved. Here, we use single-cell RNA sequencing (scRNA-seq) to identify the clonal architecture at diagnosis and after induction therapy, and elucidate the resistance pathways occurs early after upfront therapy. **Methods:** In this study, we analyzed single-cell RNA sequencing from 19 patients with newly diagnosed MM (NDMM), paired bone marrow (BM) samples after 2-4 cycles of proteasome inhibitor (PI) plus immunomodulatory drugs (IMiDS)-based induction therapy were collected and underwent scRNA-seq. By tracing transcriptional and cytogenetic PCs clones over time and performing differential expression analysis, we defined different patterns of clonal evolution and identified potential resistant pathways. **Results:** In our cohort, 12 patients were identified with more than 30 PCs in the BM samples sequenced after induction therapy. Among them, our analysis of the transcriptional and cytogenetic clonal dynamics in MM patients identified three main trajectories: patients with sensitive PC clones or clone that responds to treatment with >90% of the malignant PCs replaced with seemingly health PCs (3/12 patients, 25%); in

patients with a resistant clone that did not respond or only very partly responded to treatment, > 50% of the malignant PCs were found in the BM post-treatment (5/12 patients, 42%); and patients with clonal selection, indicating that the significant clone has been replaced by a small or undetectable clone at baseline (4/12 patients, 33%). For these four patients identified with clonal selection, one was observed with branching evolution, and the other three were observed with differential evolution. Transcriptional differences among sensitive clones, resistant clones, and selective clones were detected based on a pairwise comparison of the gene expressions. A large number of differentially expressed genes with reported MM resistant-related functions were observed in the resistant clones, including previously reported 1q-related genes such as CKS1B, HNRNPU, and H3F3A; cell cycle- and cell proliferation-related genes such as TUBA1B, STMN1, and HMGB2. For selective clones, an evident activation of the NF-kB signaling pathway was observed. **Conclusions:** Together, our study confirms that clonal dynamics of the evolving PC clones may occur early after upfront therapy, and reveals that the acquisition of therapeutic resistant pathways is associated with early adaptation to treatment.

Introduction: Quadruplet induction regimens containing daratumumab (dara-quads) are highly efficacious in newly diagnosed multiple myeloma (NDMM), producing high rates of minimal residual disease negativity and long progression-free and overall survival. Though deep clinical responses are observed in patients with conventionally defined high-risk disease, a subset of patients still progress early. We hypothesize that dara-quads may overcome traditional prognostication, with more comprehensive genomic stratification being required for individualized treatment decisions and definition of novel treatment approaches. **Methods:** We examined NDMM patients prescribed dara-quad induction at Memorial Sloan Kettering Cancer Center prior to Feb 2023, focusing on genomic characterization. **Results:** Among 205 patients analyzed, 84 patients received carfilzomib (DKRd) and 121 bortezomib (DVRd). Overall median follow-up was 1.4 years (y); 4.2y with DKRd (IQR 2.1-4.7, max 5.6) and 1.0y with DVRd (IQR 0.7-1.4, max 3.2). 25 patients progressed following DKRd and 20 following DVRd. 194 had FISH performed, 123 SNP-array, 74 targeted sequencing (MSK-IMPACT-Heme) and 45 whole genome sequencing (WGS). ISS stage did not predict for PFS or OS, either in the whole cohort, or in individual regimens. The inclusion of genomic assessment improved prognostication; while R-ISS, high-risk cytogenetics as per R-ISS, and R2-ISS each improved PFS prediction ($p< 0.01$), consideration of every feature assessable by FISH (including del1p, amp1q, t(14;20), MYC-translocations) further increased discrimination ($p=0.009$), as did considering 2 or more co-occurring high-risk features ($p=0.002$). There were trends towards potential differences between the regimens based on risk profile. Using comprehensive genomic assessment (SNP-array, MSK-IMPACT-Heme and WGS) allowed for the assessment of additional genomic features in those with adequate follow-up (predominantly DKRd). Del1p22.1 was strongly predictive of shorter PFS (RPL5, $p< 0.0001$), as were del22q12.1 (XBP1, $p=0.02$) and APOBEC-mutational activity ($p=0.01$). Additional features demonstrated a trend to significance, including del1p12 (TENT5C, $p=0.06$) and the complex structural variant chromothripsis, which may become significant upon examining a larger cohort. **Conclusions:** In the context of highly effective dara-quad induction, ISS stage did not predict for either PFS or OS. Limited cytogenetic assessment improved prognostication, while advanced genomic assessment was highly discriminatory. The current study provides the rationale for more comprehensive genomic assessment in patients receiving dara-quads in order to refine prognostication and consider novel treatment approaches for high-risk patients. With the assistance of an IMS Translational Research Award, we are significantly expanding our cohort of WGS in dara-quad-treated patients, including the integration of single-cell WGS.

patients with a resistant clone that did not respond or only very partly responded to treatment, > 50% of the malignant PCs were found in the BM post-treatment (5/12 patients, 42%); and patients with clonal selection, indicating that the significant clone has been replaced by a small or undetectable clone at baseline (4/12 patients, 33%). For these four patients identified with clonal selection, one was observed with branching evolution, and the other three were observed with differential evolution. Transcriptional differences among sensitive clones, resistant clones, and selective clones were detected based on a pairwise comparison of the gene expressions. A large number of differentially expressed genes with reported MM resistant-related functions were observed in the resistant clones, including previously reported 1q-related genes such as CKS1B, HNRNPU, and H3F3A; cell cycle- and cell proliferation-related genes such as TUBA1B, STMN1, and HMGB2. For selective clones, an evident activation of the NF-kB signaling pathway was observed. **Conclusions:** Together, our study confirms that clonal dynamics of the evolving PC clones may occur early after upfront therapy, and reveals that the acquisition of therapeutic resistant pathways is associated with early adaptation to treatment.

Introduction: Quadruplet induction regimens containing daratumumab (dara-quads) are highly efficacious in newly diagnosed multiple myeloma (NDMM), producing high rates of minimal residual disease negativity and long progression-free and overall survival. Though deep clinical responses are observed in patients with conventionally defined high-risk disease, a subset of patients still progress early. We hypothesize that dara-quads may overcome traditional prognostication, with more comprehensive genomic stratification being required for individualized treatment decisions and definition of novel treatment approaches. **Methods:** We examined NDMM patients prescribed dara-quad induction at Memorial Sloan Kettering Cancer Center prior to Feb 2023, focusing on genomic characterization. **Results:** Among 205 patients analyzed, 84 patients received carfilzomib (DKRd) and 121 bortezomib (DVRd). Overall median follow-up was 1.4 years (y); 4.2y with DKRd (IQR 2.1-4.7, max 5.6) and 1.0y with DVRd (IQR 0.7-1.4, max 3.2). 25 patients progressed following DKRd and 20 following DVRd. 194 had FISH performed, 123 SNP-array, 74 targeted sequencing (MSK-IMPACT-Heme) and 45 whole genome sequencing (WGS). ISS stage did not predict for PFS or OS, either in the whole cohort, or in individual regimens. The inclusion of genomic assessment improved prognostication; while R-ISS, high-risk cytogenetics as per R-ISS, and R2-ISS each improved PFS prediction ($p< 0.01$), consideration of every feature assessable by FISH (including del1p, amp1q, t(14;20), MYC-translocations) further increased discrimination ($p=0.009$), as did considering 2 or more co-occurring high-risk features ($p=0.002$). There were trends towards potential differences between the regimens based on risk profile. Using comprehensive genomic assessment (SNP-array, MSK-IMPACT-Heme and WGS) allowed for the assessment of additional genomic features in those with adequate follow-up (predominantly DKRd). Del1p22.1 was strongly predictive of shorter PFS (RPL5, $p< 0.0001$), as were del22q12.1 (XBP1, $p=0.02$) and APOBEC-mutational activity ($p=0.01$). Additional features demonstrated a trend to significance, including del1p12 (TENT5C, $p=0.06$) and the complex structural variant chromothripsis, which may become significant upon examining a larger cohort. **Conclusions:** In the context of highly effective dara-quad induction, ISS stage did not predict for either PFS or OS. Limited cytogenetic assessment improved prognostication, while advanced genomic assessment was highly discriminatory. The current study provides the rationale for more comprehensive genomic assessment in patients receiving dara-quads in order to refine prognostication and consider novel treatment approaches for high-risk patients. With the assistance of an IMS Translational Research Award, we are significantly expanding our cohort of WGS in dara-quad-treated patients, including the integration of single-cell WGS.

Introduction: Smoldering multiple myeloma (SMM) precedes multiple myeloma (MM). The risk of progression of SMM patients is not uniform, thus different progression-risk models have been developed, although they are mainly based on clinical parameters. Genomic predictors of progression have been defined for untreated SMM, but their usefulness in the context of trials evaluating upfront treatment in high risk SMM (HR SMM) has not been explored yet, precluding the identification of baseline genomic alterations leading to drug resistance. **Methods:** We carried out NGS and FISH studies on 57 HR SMM patients treated in the GEM-CESAR trial (NCT02415413). CD138+ plasma cells were isolated from the bone marrow; after DNA extraction, a custom NGS panel was used to sequence 145 Kb from 666 target regions, allowing the detection of SNV and indels located in 38 genes previously reported in the literature as relevant in MM. FISH studies included probes to detect the following alterations: t(4;14), t(14;16), del17p, t(11;14), 1q gain or amplification (+1q), del1p and structural aberrations in the MYC locus. **Results:** According to the 2014 IMWG definition, 44 patients met the current criteria to be considered HR SMM at diagnosis, while the remaining 13 cases, originally classified as ultra−high risk (UHR), had active disease at baseline following the actual criteria. The median number of SNV/indels per patient was 1 (range: 0−9), with 11/57 patients (19.3%) harboring no alterations in the studied genes. The mutational profile of these patients was enriched in alterations involving well-known drivers in MM (KRAS, NRAS, DIS3, FAM46C). MAPK pathway gene mutations were the most abundant (52.6%), followed by those belonging to RNA and protein processing (22.8%). In 7 patients we identified more than one SNV and/or indel in the same gene (multihit mutations). Concerning cytogenetics, frequencies were closer to symptomatic MM, although some aberrations were enriched in HR SMM compared to the general SMM population [t(4;14) and +1q]. On the contrary, 1p deletions were infrequent (3.8%) and double-hit TP53 alterations absent. Interestingly, FGFR3 mutations were frequently accompanied by t(4;14): 7/8 cases with FGFR3 mutations also harbored the translocation. Previously described risk factors of progression in SMM (mutations in the MAPK pathway, structural alterations affecting MYC and aberrations in the DNA repair pathway) did not predict early biological or clinical progression. In our cohort, NRAS mutations (HR: 5.45, 95% CI: 1.57−18.93, p=0.008) and the co-occurrence of t(4;14) with FGFR3 mutations (HR: 6.75, 95% CI: 1.87−24.34, p=0.004) were associated with a higher risk of biological progression. **Conclusions:** The mutational profile of HR SMM patients is similar to symptomatic MM. If validated in larger studies, t(4;14) plus FGFR3 mutations, or NRAS mutations, could be used to predict resistance and a shorter time to disease progression.

Introduction: Previous research on APOBEC3B (A3B) in multiple myeloma (MM) has predominantly focused on APOBEC mutation signatures. However, the role of A3B mRNA expression level and its impact on MM cellular characteristics remains poorly understood. This study aims to investigate the prognostic significance of A3B mRNA expression in MM progression and explore its downstream effects through in vitro experiments. **Methods:** The prognostic significance of A3B mRNA expression level in the CoMMpass dataset was investigated using Univariate Cox regression and Kaplan-Meier Curve analysis. Additionally, a pathways analysis (KEGG/REACTOME) was conducted to identify biological functions that were significantly overrepresented in genes correlated with A3B expression. Lentiviral knockdown (KD) and overexpression (OE) of A3B were performed in MM cell lines, followed by RNA-seq and pathway analysis to identify shared pathways through parallel analysis. The obtained results were subsequently tested and validated in vitro. **Results:** A3B expression level showed the highest hazard ratio (HROS:2.60; HRPFS:2.32, p20%) and exhibiting high A3B mRNA expression levels (4th quartile) display a significant (p< 0.05) enrichment of APOBEC-induced genomic mutations, along with a worse prognosis (median PFS: 500 days), in comparison to patients with intermediate (2nd and 3rd quartile) (median PFS: 1000 days) and low (1st quartile) A3B expression levels (median PFS: 1900 days). **Conclusions:** These findings highlight the substantial involvement of A3B in cell proliferation and genomic instability in MM. This identifies A3B as a promising candidate for targeted interventions aimed at mitigating DNA damage and genomic instability in MM cells, particularly among patients with del(17p).

Introduction: Multiple Myeloma (MM) is a hematologic cancer with heterogeneous and complex genomic landscape, where Copy Number Alterations (CNAs) play a key role in the disease's pathogenesis and prognosis. It is of biological and clinical interest to study the temporal occurrence of early alterations, as they play a disease "driver" function by deregulating key tumor pathways. **Methods:** This study presents an innovative bioinformatic suite consisting of five bioinformatics tools (BOBaFit, RemasterCNA, RAPH, ComphyNumber and TestClonality) created for the purpose of harmonizing Copy Number data across different genomic platforms and tracing the origin of CNAs throughout the evolutionary history of MM. To this aim, large cohorts of newly-diagnosed MM (NDMM, N=1582) and Smoldering-MM (SMM, N=282) were aggregated. **Results:** The tools developed in this study enabled the harmonization of CNAs as obtained from different genomic platforms (i.e. WGS, ULP-WGS, WES, SNP array) in order to obtain the highest statistical power. Therefore, the high numerosity of these cohorts was harnessed for both 1) the identification of novel genes characterized as MM focal "driver" alterations through the optimized use of GISTIC tool (including NFKB2, NOTCH2, MAX and EVI5 and MYC-ME2-enhancer genes), and 2) the generation of an innovative timing model based on Bradley-Terry approach and implemented with the introduction of a statistical method aimed at introducing statistical confidence intervals for CNAs analysis. By applying this model on both NDMM and SMM cohorts, it has been possible to identify specific CNAs (1q(CKS1B)amp, 13q(RB1)del, 11q(CCND1)amp and 14q(MAX)del) that were categorized as "early/driver" events. A high level of precision was guaranteed by the narrow confidence intervals in the timing estimates. These CNAs were proposed as critical MM alterations, playing a critical role in the evolutionary history of both SMM and NDMM. Importantly, among the identified events, CKS1B amp and RB1 del were previously poorly characterized from an evolutionary point of view and uncertainly classified between primary and secondary events, while MAX del represents a completely new discovered MM driver alteration. Finally, a stepwise backward-forward Cox Regression survival model was employed to identify all the independent genomic alterations having the greatest effect on patients' outcomes (i.e. Progression Free and Overall Survival), named deletion of RB1, amplification of CKS1B, amplification of MYC, amplification NOTCH2 and deletion-mutation of TRAF3. **Conclusions:** In conclusion, the study highlighted the existence of previously unrecognized "early-drivers" MM CNAs, whose impact on patients' survival has been demonstrated. These CNAs might improve MM patients' stratification and contribute to precisely assess patients' prognosis. **Acknowledgements:** BolognAIL ONLUS, AIRC19-IG22059.

Introduction: Intratumor heterogeneity as a clinical challenge becomes most evident after several treatment lines when multi-drug resistant subclones accumulate. With the hypothesis that the characterization of resistance mechanisms at the subclonal level is key to identify common vulnerabilities, we performed a longitudinal single-cell (sc) sequencing study in relapsed/refractory multiple myeloma (RRMM). **Methods:** scRNA- and ATAC-sequencing together with whole genome sequencing (WGS) was performed for 15 RRMM patients with longitudinal samples (T1/T2). Tumor subclones were identified based on copy number aberrations in both sc readouts. To match transcriptome and epigenome of each subclone, a WGS-guided clustering approach was developed and combined with mitochondrial DNA mutations. Cell-cell interactions between subclones and the bone marrow microenvironment (BME) were identified using CellChat. **Results:** Analyzing the impact of treatment on individual subclones, we found converging adaptation

Introduction: Multiple Myeloma (MM) is a hematologic cancer with heterogeneous and complex genomic landscape, where Copy Number Alterations (CNAs) play a key role in the disease's pathogenesis and prognosis. It is of biological and clinical interest to study the temporal occurrence of early alterations, as they play a disease "driver" function by deregulating key tumor pathways. **Methods:** This study presents an innovative bioinformatic suite consisting of five bioinformatics tools (BOBaFit, RemasterCNA, RAPH, ComphyNumber and TestClonality) created for the purpose of harmonizing Copy Number data across different genomic platforms and tracing the origin of CNAs throughout the evolutionary history of MM. To this aim, large cohorts of newly-diagnosed MM (NDMM, N=1582) and Smoldering-MM (SMM, N=282) were aggregated. **Results:** The tools developed in this study enabled the harmonization of CNAs as obtained from different genomic platforms (i.e. WGS, ULP-WGS, WES, SNP array) in order to obtain the highest statistical power. Therefore, the high numerosity of these cohorts was harnessed for both 1) the identification of novel genes characterized as MM focal "driver" alterations through the optimized use of GISTIC tool (including NFKB2, NOTCH2, MAX and EVI5 and MYC-ME2-enhancer genes), and 2) the generation of an innovative timing model based on Bradley-Terry approach and implemented with the introduction of a statistical method aimed at introducing statistical confidence intervals for CNAs analysis. By applying this model on both NDMM and SMM cohorts, it has been possible to identify specific CNAs (1q(CKS1B)amp, 13q(RB1)del, 11q(CCND1)amp and 14q(MAX)del) that were categorized as "early/driver" events. A high level of precision was guaranteed by the narrow confidence intervals in the timing estimates. These CNAs were proposed as critical MM alterations, playing a critical role in the evolutionary history of both SMM and NDMM. Importantly, among the identified events, CKS1B amp and RB1 del were previously poorly characterized from an evolutionary point of view and uncertainly classified between primary and secondary events, while MAX del represents a completely new discovered MM driver alteration. Finally, a stepwise backward-forward Cox Regression survival model was employed to identify all the independent genomic alterations having the greatest effect on patients' outcomes (i.e. Progression Free and Overall Survival), named deletion of RB1, amplification of CKS1B, amplification of MYC, amplification NOTCH2 and deletion-mutation of TRAF3. **Conclusions:** In conclusion, the study highlighted the existence of previously unrecognized "early-drivers" MM CNAs, whose impact on patients' survival has been demonstrated. These CNAs might improve MM patients' stratification and contribute to precisely assess patients' prognosis. **Acknowledgements:** BolognAIL ONLUS, AIRC19-IG22059.

Introduction: Intratumor heterogeneity as a clinical challenge becomes most evident after several treatment lines when multi-drug resistant subclones accumulate. With the hypothesis that the characterization of resistance mechanisms at the subclonal level is key to identify common vulnerabilities, we performed a longitudinal single-cell (sc) sequencing study in relapsed/refractory multiple myeloma (RRMM). **Methods:** scRNA- and ATAC-sequencing together with whole genome sequencing (WGS) was performed for 15 RRMM patients with longitudinal samples (T1/T2). Tumor subclones were identified based on copy number aberrations in both sc readouts. To match transcriptome and epigenome of each subclone, a WGS-guided clustering approach was developed and combined with mitochondrial DNA mutations. Cell-cell interactions between subclones and the bone marrow microenvironment (BME) were identified using CellChat. **Results:** Analyzing the impact of treatment on individual subclones, we found converging adaptation

mechanisms in patients with stable evolution or only minor changes in the subclonal architecture. Specifically, 86% (range: 64-96%) of therapy-induced changes in gene expression were shared across individual subclones for each patient and the same was seen for transcription factor (TF) motif activities (93 % shared (range: 71-95 %)). This included a significant upregulation of genes and TF motifs of the NFKB pathway upon MEK/BRAF inhibition and of heat-shock proteins upon proteasome inhibition. Next, we focused on patients with major subclonal changes and found evidence for a role of the BME in differential treatment response. Global gene expression and chromatin accessibility analysis in a patient treated with an MCL1 inhibitor revealed subclonal differences in expression of the cell-cell interaction molecule CD44. According to CellChat, CD44 mediated a subclone-specific interaction with monocytes and dendritic cells that was lost upon MCL1 inhibition. Extending the interaction analysis to all patients with multiple subclones, on average 32 ligand-receptor interactions were predicted per patient. Notably, 20% of them were not shared between subclones. These unshared interactions were mainly mediated by the intercellular adhesion molecule (ICAM) signaling network. Despite this heterogeneity in ICAMs, they still represent a potential treatment target. We found ICAM1 to be significantly upregulated upon treatment (p=0.02), including a patient with ICAM1-mediated interactions in all subclones at T2, which were not detectable at T1. In line with this, we found a higher co-accessibility at the ICAM1 promoter and motif activity for TFs regulating ICAM1 such as IRF4 in all subclones. **Conclusions:** Our multi-omics approach of individual subclones integrates multiple layers of resistance. These mechanisms can occur in parallel, which emphasizes the development of strategies that target shared vulnerabilities across individual subclones.

Sequential and persistent loss of BCMA and GPRC5D after bispecific antibodies in multiple myeloma revealed by whole genome sequencing

Leo Rasche[1], Marietta Truger[2], Umair Munawar[1], Moutaz Helal[1], Seungbin Han[1], Xiang Zhou[1], Florian Eisele[1], Christine Riedhammer[1], Johannes Duell[1], Manja Meggendorfer[2], Heiko Müller[2], Johannes Waldschmidt[1], Julia Mersi[1], Franziska Panther[1], Andreas Rosenwald[1], Claudia Haferlach[2], Hermann Einsele[1], Martin Kortüm[1]

[1]University Hospital Würzburg; [2]MLL Munich

Introduction: We and others have recently identified biallelic hits in genes coding for immunotherapy targets in Multiple Myeloma (MM) as a mechanism of resistance, such as in BCMA. Similarly, biallelic events in the GPRC5D locus on chromosome 12p have been linked to antigen loss and relapse from GPRC5D targeted therapies. As we are entering an era in which BCMA and GPRC5D targeting agents are approved and available, the question how to sequentially treat patients with anti-BCMA and anti-GPRC5D agents becomes imminent. A more profound knowledge about the selective pressure of sequential immunotherapy on the clonal architecture in MM is key to inform successful sequencing strategies. **Methods:** We applied serial whole genome sequencing (WGS, 100x coverage, 2x151 bp, NovaSeq instrument) and immunohistochemistry (IHC) studies in a patient with RRMM who was treated with 10 lines of therapy with literally all available drugs including BCMA and GPRC5D targeting agents. **Results:** WGS revealed several illustrating genomic events: First, a homozygous BCMA deletion conferring antigen loss after treatment with a BCMA targeting T-cell redirecting bispecific antibody. This biallelic hit was characterized by monosomy 16 and a small deletion on the remaining allele of 586 kb. IHC confirmed BCMA loss on the protein level. Second, 2.5 years later, the patient was treated with a GPRC5D targeting bispecific antibody and again achieved deep remission lasting for 15-months. At subsequent relapse WGS displayed an acquired 12p deletion of 23.3 Mb including GPRC5D and IHC confirmed GPRC5D loss to underlie relapse. The homozygous BCMA deletion was persistent at this time point, highlighting two sequential evolutionary bottlenecks. Next to the loss of immunotargets, two additional genetic lesions associated to the therapy applied were tracked in this patient: the SBS-MM1 signature, in 12.8% of mutations, which is linked to melphalan exposure, and a clonal truncating mutation in CRBN (p.Gln8Ter), inducing IMiD resistance, that was developed upon 3rd line treatment. **Conclusions:** Immunotherapy is an evolutionary bottleneck in the treatment of MM, selecting for antigen loss variants. Sequential mono-immunotherapies may enforce such selection, arguing for multi-specific strategies to circumvent antigen loss. Tumor-intrinsic mechanisms largely explain resistance in our exemplary patient, highlighting WGS of purified MM cells as a promising diagnostic tool to follow-up patients in the era of novel immunotherapies., In our patient the genome could be read as a book in which prior therapies had been noted.

Introduction: Multiple Myeloma (MM) is a mature B cell neoplasm distinguished by the accumulation of plasma cells (PCs) within the bone marrow (BM). Despite treatment advances, MM remains incurable in the majority of patients. The failure to achieve pervasive cure in MM despite the attainment of deep PC responses with PIs, IMiDs, anti-CD38 mAb, melphalan and SCT, bispecific antibodies and CAR-T, suggests the existence of intra-tumoral heterogeneity and rare drug-resistant MM cells with full tumorigenic capacity. **Methods:** We examined MM patient BM samples using a combination of FACS, single cell protein immunoflourescence-FISH (IF-FISH), whole exome sequencing (WES), custom-capture targeted deep sequencing (CC-Seq) and single cell RNA sequencing (scRNAseq) to characterize the genomic landscape of intraclonal MM cell subpopulations and to track these subpopulations over time in patients. **Results:** FACS-IF-FISH studies of MM patient BM samples (n=140) identified MM progenitor subpopulations

mechanisms in patients with stable evolution or only minor changes in the subclonal architecture. Specifically, 86% (range: 64-96%) of therapy-induced changes in gene expression were shared across individual subclones for each patient and the same was seen for transcription factor (TF) motif activities (93 % shared (range: 71-95 %)). [1]University of Auckland; [2]Princess Margaret Cancer Centre

Introduction: Multiple Myeloma (MM) is a mature B cell neoplasm distinguished by the accumulation of plasma cells (PCs) within the bone marrow (BM). Despite treatment advances, MM remains incurable in the majority of patients. The failure to achieve pervasive cure in MM despite the attainment of deep PC responses with PIs, IMiDs, anti-CD38 mAb, melphalan and SCT, bispecific antibodies and CAR-T, suggests the existence of intra-tumoral heterogeneity and rare drug-resistant MM cells with full tumorigenic capacity. **Methods:** We examined MM patient BM samples using a combination of FACS, single cell protein immunoflourescence-FISH (IF-FISH), whole exome sequencing (WES), custom-capture targeted deep sequencing (CC-Seq) and single cell RNA sequencing (scRNAseq) to characterize the genomic landscape of intraclonal MM cell subpopulations and to track these subpopulations over time in patients. **Results:** FACS-IF-FISH studies of MM patient BM samples (n=140) identified MM progenitor subpopulations

that resemble the maturation stages of post germinal centre B cells through to PCs. These clonal subpopulations include rare MM cells that resemble CD20+CD38-CD138-Irf4- Xbp1s- B cells, CD20-CD38-CD138-Irf4-Xbp1s- pre-plasmablasts and CD38+CD138-Irf4+XBP1s+ pre-PCs, as well as tumor-bulk CD38+CD138+IRF4+Xbp1s+ PCs. MM progenitors possess all of the chromosomal translocations and copy number variations (CNV) present in MM PCs including ploidy changes, translocations such as t(4;14), t(14;16) and t(11;14), and secondary aberrations such as gain(1q), del(1p) and del(17p). To examine if MM progenitor cells also possess the single nucleotide variations (SNV) present within MM PCs, and are thus fully malignant, and to track MM progenitor subpopulations within patients over time, we performed WES (n=60) plus CC-Seq (n=210) on purified cell subpopulations from 17 patients, including 5 whom we sampled serially over >3 years. Five cellular subpopulations were isolated from each BM, and each was sequenced to a depth of 4–20,000x. From these data, SNVs in tumor-bulk MM PCs were regularly detected in MM progenitors, although the low frequency of progenitors often prevented capture of complete SNV profiles. Notably, analyses of serial BM samples taken pre and post treatment suggests that relapsing MM PCs typically do not derive from pre-treatment PCs, and often lack multiple SNVs present in pre-treatment PCs. Instead, crucially, relapsing MM PCs commonly derive from MM progenitor cells, as relapse-specific SNVs present in relapsing PCs were detected within MM B cells and progenitor cells isolated from BMs collected up to 3 years prior to relapse. Moreover MM progenitors were also detected as the sole MRD in PC-negative patients. **Conclusions:** MM B cells and progenitors possess all of the genomic aberrations required for full malignant potential. Tracking of these cells in vivo in patients by their SNV profile implicates them as the cellular origin of disease relapse. Cure of MM requires eradication of MM progenitor cells.

[1]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College; [2]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem

Introduction: A growing body of evidence has indicated impaired function or compositional changes of monocytes in inflammatory disorders, such as acute respiratory syndrome and covid-19. In multiple myeloma (MM) tumor microenvironment, activation of type I interferon pathway and dysregulated expression of major histocompatibility complex type II genes are observed in classical monocytes, which result in loss of antigen presentation of monocytes. The proportions of BAFF+PD-L1+ monocytes in the bone marrow also correlate with survival of myeloma patients following chimeric antigen-receptor T cell therapy. Nevertheless, the mechanisms underlying monocytes defects in MM remain poorly addressed, at least in part by the lack of large scale scRNA-seq studies. **Methods:** To resolve the heterogeneous bone marrow (BM) and peripheral blood (PB) monocyte subpopulations and their transcriptional factors between healthy donors (HD) and MM patients. We performed scRNA-seq on monocytes of 7 newly diagnosed MM (NDMM) patients and 12 HD. Specifically, 3 and 5 BM samples and 9 and 7 PB samples of 12 HD and 7 NDMM patients were obtained and sequenced. **Results:** Here, we employed scRNA-seq technology to systematically analyze 26,683 BM and 82,328 circulating monocytes, and genetically defined their subpopulations. We constructed a precise atlas of human PB and BM monocytes, identified seven subpopulations in both BM and PB—including S100A12, HLA, ISG15, CD16, proinflammatory, and intermediate in both BM and PB; megakaryocyte-like in PB; and proliferating subset in BM. Differential expression analysis on the BM and PB monocytes showed that a large number of type I interferon (IFN) signaling pathway genes (e.g. IFI27, IFI6, ISG15) were overexpressed in MM compared with HD. Genes encoding major complement system components and class II major histocompatibility complex molecules (MHC class II) were more highly expressed in MM compared to HD, indicating higher inflammatory and phagocytic potential of MM monocytes. However, relative to HD, T-cell attraction-related genes (e.g. CCL3 and CCL4) were markedly downregulated in MM, and T-cell suppression-related genes (e.g. IDO1, CD274 and PDCD1LG2) were markedly upregulated in MM. Furthermore, we identified two monocyte differentiation pathways in both BM and PB, and discovered that BM monocyte feature type I IFN-associated alterations in differentiation in patients with MM as well as dysregulated patterns at transcriptome. Finally, we included 10 MM patients as a validation cohort, by tracking the alterations in transcriptome and differentiation during treatment using scRNA-seq. Our results indicated that type I IFN signaling pathway activation and alterations in differentiation was partially alleviated for BM monocytes in MM by antitumor therapy. **Conclusions:** Our results provided further insight into transcriptional and differentiation alterations occurring in the BM and PB monocytes from patients with MM and explored mechanisms of immune evasion associated with monocytes.

Introduction: A growing body of evidence has indicated impaired function or compositional changes of monocytes in inflammatory disorders, such as acute respiratory syndrome and covid-19. In multiple myeloma (MM) tumor microenvironment, activation of type I interferon pathway and dysregulated expression of major histocompatibility complex type II genes are observed in classical monocytes, which result in loss of antigen presentation of monocytes. The proportions of BAFF+PD-L1+ monocytes in the bone marrow also correlate with survival of myeloma patients following chimeric antigen-receptor T cell therapy. Nevertheless, the mechanisms underlying monocytes defects in MM remain poorly addressed, at least in part by the lack of large scale scRNA-seq studies. **Methods:** To resolve the heterogeneous bone marrow (BM) and peripheral blood (PB) monocyte subpopulations and their transcriptional factors between healthy donors (HD) and MM patients. We performed scRNA-seq on monocytes of 7 newly diagnosed MM (NDMM) patients and 12 HD. Specifically, 3 and 5 BM samples and 9 and 7 PB samples of 12 HD and 7 NDMM patients were obtained and sequenced. **Results:** Here, we employed scRNA-seq technology to systematically analyze 26,683 BM and 82,328 circulating monocytes, and genetically defined their subpopulations. We constructed a precise atlas of human PB and BM monocytes, identified seven subpopulations in both BM and PB—including S100A12, HLA, ISG15, CD16, proinflammatory, and intermediate in both BM and PB; megakaryocyte-like in PB; and proliferating subset in BM. Differential expression analysis on the BM and PB monocytes showed that a large number of type I interferon (IFN) signaling pathway genes (e.g. IFI27, IFI6, ISG15) were overexpressed in MM compared with HD. Genes encoding major complement system components and class II major histocompatibility complex molecules (MHC class II) were more highly expressed in MM compared to HD, indicating higher inflammatory and phagocytic potential of MM monocytes. However, relative to HD, T-cell attraction-related genes (e.g. CCL3 and CCL4) were markedly downregulated in MM, and T-cell suppression-related genes (e.g. IDO1, CD274 and PDCD1LG2) were markedly upregulated in MM. Furthermore, we identified two monocyte differentiation pathways in both BM and PB, and discovered that BM monocyte feature type I IFN-associated alterations in differentiation in patients with MM as well as dysregulated patterns at transcriptome. Finally, we included 10 MM patients as a validation cohort, by tracking the alterations in transcriptome and differentiation during treatment using scRNA-seq. Our results indicated that type I IFN signaling pathway activation and alterations in differentiation was partially alleviated for BM monocytes in MM by antitumor therapy. **Conclusions:** Our results provided further insight into transcriptional and differentiation alterations occurring in the BM and PB monocytes from patients with MM and explored mechanisms of immune evasion associated with monocytes.

that resemble the maturation stages of post germinal centre B cells through to PCs. These clonal subpopulations include rare MM cells that resemble CD20+CD38-CD138-Irf4- Xbp1s- B cells, CD20-CD38-CD138-Irf4-Xbp1s- pre-plasmablasts and CD38+CD138-Irf4+XBP1s+ pre-PCs, as well as tumor-bulk CD38+CD138+IRF4+Xbp1s+ PCs. MM progenitors possess all of the chromosomal translocations and copy number variations (CNV) present in MM PCs including ploidy changes, translocations such as t(4;14), t(14;16) and t(11;14), and secondary aberrations such as gain(1q), del(1p) and del(17p). To examine if MM progenitor cells also possess the single nucleotide variations (SNV) present within MM PCs, and are thus fully malignant, and to track MM progenitor subpopulations within patients over time, we performed WES (n=60) plus CC-Seq (n=210) on purified cell subpopulations from 17 patients, including 5 whom we sampled serially over >3 years. Five cellular subpopulations were isolated from each BM, and each was sequenced to a depth of 4–20,000x. From these data, SNVs in tumor-bulk MM PCs were regularly detected in MM progenitors, although the low frequency of progenitors often prevented capture of complete SNV profiles. Notably, analyses of serial BM samples taken pre and post treatment suggests that relapsing MM PCs typically do not derive from pre-treatment PCs, and often lack multiple SNVs present in pre-treatment PCs. Instead, crucially, relapsing MM PCs commonly derive from MM progenitor cells, as relapse-specific SNVs present in relapsing PCs were detected within MM B cells and progenitor cells isolated from BMs collected up to 3 years prior to relapse. Moreover MM progenitors were also detected as the sole MRD in PC-negative patients. **Conclusions:** MM B cells and progenitors possess all of the genomic aberrations required for full malignant potential. Tracking of these cells in vivo in patients by their SNV profile implicates them as the cellular origin of disease relapse. Cure of MM requires eradication of MM progenitor cells.

Introduction: Alterations within the bone marrow microenvironment (BMME) may contribute to the progression of multiple myeloma (MM) from its precursor stages. The significance of the BMME and the role of different immune cell types in the progression of myeloma could identify novel therapeutic approaches to prevent the progression of disease. Here we investigated the frequency of different immune cell types in the BMME at different stages of myeloma and their interactions with the tumor cells. **Methods:** BM aspirates from smoldering multiple myeloma (SMM; n=10), newly diagnosed multiple myeloma (NDMM; n=23), and relapsed/refractory multiple myeloma (RRMM; n=22) patients were collected from the Indiana Myeloma Registry. BM mononuclear cells were isolated by Ficoll and underwent CD138 magnetic bead selection into CD138+ and CD138- fractions. CD138- samples underwent scRNA and TCR sequencing (10X Genomics) and CD138+ samples underwent multiomic analysis (10x Genomics). CD138- data was normalized, integrated, and clusters were annotated for cell type using Seurat (v4), resulting in 315,533 high quality immune cells. Significant proportional and gene expression differences between clusters at different disease stages were calculated. Quantitative analysis on intercellular communication networks were analyzed between single cell clusters of matched CD138+ cells and CD138- samples using CellChat (v1.6.0). **Results:** Integration of all 55 CD138- samples resulted in 36 immune cell subclusters. Despite patient heterogeneity, significant changes in the immune cell proportions were identified as the disease progressed; a substantial decrease in CD4 memory T cells from NDMM to RRMM (P< 0.0001) (SMM=15.7%; NDMM=13.4%; RRMM=4%) whereas CD4 T effector cells significantly increased from NDMM to RRMM (P=0.005) (SMM=10.8%; NDMM=8.7%; RRMM=11.9%) and CD8 T MAIT cells decreased from NDMM to RRMM (P=0.002). CD56 natural killer cells increased (SMM=1.6%; NDMM=2.7%; RRMM=5.2%; P< 0.05) as did CD16 monocyte cell clusters (SMM=0.9%; NDMM=1.9%; RRMM=4.3%; P< 0.05). Regarding tumor-BMME intercellular communication, we observed known APRIL-BCMA and BAFF-BCMA/BAFF-TACI interactions between myeloid dendritic cells or monocyte clusters and tumor cell clusters. Our single cell data shows these interactions decreased from SMM to NDMM and RRMM (P< 0.05). In addition, RRMM samples had a significant increase in MIF-CD74/CXCR4 interactions between tumor cells and myeloid dendritic cells compared to SMM and NDMM cells (P< 0.05), which can contribute to the immune evasion of myeloma cells and limit the effectiveness of immune-based therapies. **Conclusions:** Immune cell subgroups change as the disease progresses from SMM to NDMM and RRMM, as do their interactions with myeloma cells possibly resulting in increased resistance through immune evasion and MIF signaling mechanisms.

Introduction: Multiple myeloma (MM) is a malignancy of clonal plasma cells with identical VDJ recombination of immunoglobulin loci (called repertoire) and extensive genome or transcriptome heterogeneity. Even though many new treatment modalities have been developed to extend patient survival, most cases remain incurable. Recent evidence suggests that intra-tumor heterogeneity underlies the therapy resistance, but its details remain largely unknown. **Methods:** To understand the comprehensive architecture, we subdivided bone marrow (BM) cells from MM patients at different disease stages (n=8) into 11 fractions by flow cytometry (FCM) and performed bulk RNA sequencing (bulk RNA-seq). Using BM cells with MM sorted by the panel established based on clonal repertoire distribution, we performed single-cell RNA sequencing (scRNA-seq) coupled with VDJ targeted sequencing (scVDJ-seq) (n=11) including those at diagnosis and in remission with minimal residual disease (MRD). **Results:** RNA sequencing-based profiling of repertoire revealed that tumor cells are also detected in Lineage marker– (Lin–)/ CD19–/CD38++/CD138– fraction other than the main fraction (Lin–/CD19–/CD38++/CD138+) regardless of disease stage. An analysis of scRNA-seq coupled with scVDJ-seq on Lin–/CD19–/CD38+ fraction, without CD138 gating, discriminated MM cells (20084 cells) clearly from others. By integration with gene signatures established from bulk RNA-seq of CD138+ and CD138– MM cells (n=12), the heterogeneity on the CD138 axis was also unraveled. FCM analysis confirmed that CD138– MM cells were present at a rate of less than 10% across the disease stages (n=59), which showed unique morphology, methylation of histone H3K4 and cell cycle status distinct from CD138+ cells. Primary cell culture and trajectory/velocity analysis of scRNA-seq suggested that heterogeneity along the CD138 axis might be regulated by epigenetic plasticity. Interestingly, we identified unique clusters in the CD138– population which tended to remain at high proportions after treatment. They were characterized by low expression of MHC class-I genes and BCMA as well as 198 upregulated genes, including MCL1, MALAT1, NEAT1, which have been previously implicated in treatment resistance. We systematically interrogated their dependencies in growth of MM cells using a custom CRISPR/Cas9 screening system and narrowed down several important genes. Analysis of public databases showed

Introduction: Multiple myeloma (MM) is a malignancy of clonal plasma cells with identical VDJ recombination of immunoglobulin loci (called repertoire) and extensive genome or transcriptome heterogeneity. Even though many new treatment modalities have been developed to extend patient survival, most cases remain incurable. Recent evidence suggests that intra-tumor heterogeneity underlies the therapy resistance, but its details remain largely unknown. **Methods:** To understand the comprehensive architecture, we subdivided bone marrow (BM) cells from MM patients at different disease stages (n=8) into 11 fractions by flow cytometry (FCM) and performed bulk RNA sequencing (bulk RNA-seq). Using BM cells with MM sorted by the panel established based on clonal repertoire distribution, we performed single-cell RNA sequencing (scRNA-seq) coupled with VDJ targeted sequencing (scVDJ-seq) (n=11) including those at diagnosis and in remission with minimal residual disease (MRD). **Results:** RNA sequencing-based profiling of repertoire revealed that tumor cells are also detected in Lineage marker– (Lin–)/ CD19–/CD38++/CD138– fraction other than the main fraction (Lin–/CD19–/CD38++/CD138+) regardless of disease stage. An analysis of scRNA-seq coupled with scVDJ-seq on Lin–/CD19–/CD38+ fraction, without CD138 gating, discriminated MM cells (20084 cells) clearly from others. By integration with gene signatures established from bulk RNA-seq of CD138+ and CD138– MM cells (n=12), the heterogeneity on the CD138 axis was also unraveled. FCM analysis confirmed that CD138– MM cells were present at a rate of less than 10% across the disease stages (n=59), which showed unique morphology, methylation of histone H3K4 and cell cycle status distinct from CD138+ cells. Primary cell culture and trajectory/velocity analysis of scRNA-seq suggested that heterogeneity along the CD138 axis might be regulated by epigenetic plasticity. Interestingly, we identified unique clusters in the CD138– population which tended to remain at high proportions after treatment. They were characterized by low expression of MHC class-I genes and BCMA as well as 198 upregulated genes, including MCL1, MALAT1, NEAT1, which have been previously implicated in treatment resistance. We systematically interrogated their dependencies in growth of MM cells using a custom CRISPR/Cas9 screening system and narrowed down several important genes. Analysis of public databases showed

that high expression of a part of these genes, including RNA-binding protein 39 (RBM39), are significantly associated with poor prognosis. We confirmed that RBM39 is indispensable for the MM cells by CRISPR/Cas9-mediated knockout and pharmacological protein degradation. **Conclusions:** We achieved a complete view of MM diversity that was not limited by cell surface antigens or transcriptome characteristics by using repertoire clonality. Our results highlight a novel subpopulation as a candidate therapeutic target for cure.

Introduction: Venetoclax (Ven) is a potent, oral BCL-2 inhibitor under investigation for t(11;14)+ relapsed/refractory multiple myeloma (RRMM). The dose-finding part of a Phase 2 study (NCT02899052) of Ven plus carfilzomib (K) and dexamethasone (d) in RRMM showed an overall response rate (ORR) of 80%, and ORR was higher in patients (pts) who were t(11;14)+ vs t(11;14)– (92 vs 75%; Costa, Blood Adv. 2021;5:3748). Here, we report initial safety and efficacy data in patients with t(11;14)+ RRMM treated with Ven (400 or 800 mg) combined with K (70 mg/m^2) and d (Ven400Kd or Ven800Kd) vs Kd alone in the dose-finding and randomized parts of the study. **Methods:** Pts with t(11;14)+ RRMM were randomized 5:3:5 to receive K (70 mg/m^2 weekly) and d (40 mg) plus daily Ven (Ven400Kd or Ven800Kd), or Kd alone. Pts in the randomized part had ≥1 prior line of therapy (LOT); pts in dose finding had 1–3 prior LOT. Primary objectives of the randomized part were to assess safety and efficacy. Secondary objectives were to assess progression-free survival (PFS), overall survival (OS), time to response (TTR), time to progression (TTP), and duration of response (DOR). Efficacy was analyzed in pts randomized to Ven400Kd, enrolled during dose finding or randomized to Ven800Kd, and randomized to Kd. Safety was analyzed in those who received ≥1 dose of study treatment. **Results:** At the 19 Jan 2023 cutoff, 48 randomized pts and 8 pts from dose finding were included (Ven400Kd, n=17; Ven800Kd, n=20; Kd, n=19); 1 pt in the Kd group was not treated. Pts had median age of 70.5–73 years, median 2 prior LOT, and had prior exposure to proteasome inhibitors (89–94%), immunomodulatory drugs (85–89%), and anti-CD38 mAb (24–47%). Treatment-emergent adverse events (TEAEs) occurring at ≥50% in any group (Ven400Kd vs Ven800Kd vs Kd) were diarrhea (65 vs 75 vs 6%), nausea (53 vs 55 vs 28%), fatigue (35 vs 50 vs 22%), and vomiting (0 vs 50 vs 11%). Grade ≥3 TEAEs occurred in 88, 85, and 72% of pts. Grade ≥3 TEAEs occurring at ≥20% in any group were lymphopenia (18 vs 30 vs 6%), neutropenia (12 vs 25 vs 11%), and hypertension (24 vs 15 vs 17%). Few Grade ≥3 cardiac disorders occurred (0 vs 5 vs 6%). Grade ≥3 infection rates were higher in the VenKd groups vs Kd (29 vs 20 vs 11%). At median follow-ups (range) of 16.8 (5.8–30.8), 21.1 (2.2–65.8), and 11.5 (0.0–28.3) months in the Ven400Kd, Ven800Kd, and Kd groups, respectively, corresponding ORRs (95% CI) were 94% (71–100), 95% (75–100), and 58% (34–80). Complete response (CR)/stringent CR rates were 29, 50, and 11%, respectively. Median TTR was 1.0, 1.0, and 2.4 months. 12-month PFS estimates were 67, 85, and 79%, with median PFS of 42.4 months (hazard ratio vs Kd=0.613 [95% CI, 0.153–2.456]) in the Ven800Kd group and not reached (NR) in the Ven400Kd and Kd groups. Medians for OS, TTP, and DOR were NR in any group. More mature data will be presented. **Conclusions:** Treatment with VenKd was well tolerated and produced favorable responses in >90% of pts with t(11;14)+ RRMM. Enrollment is ongoing.

Introduction: Although proteasome inhibitors (PIs) have transformed management of multiple myeloma (MM), drug resistance emerges through induction of the aggresome & autophagy pathway as a compensatory protein clearance mechanism. Accordingly, autophagy inhibitors used in association to conventional anti-MM drugs might enforce the effect against resistant MM cells and render autophagy a new therapeutic target.

that high expression of a part of these genes, including RNA-binding protein 39 (RBM39), are significantly associated with poor prognosis. We confirmed that RBM39 is indispensable for the MM cells by CRISPR/Cas9-mediated knockout and pharmacological protein degradation. **Conclusions:** We achieved a complete view of MM diversity that was not limited by cell surface antigens or transcriptome characteristics by using repertoire clonality. Introduction: Venetoclax (Ven) is a potent, oral BCL-2 inhibitor under investigation for t(11;14)+ relapsed/refractory multiple myeloma (RRMM). The dose-finding part of a Phase 2 study (NCT02899052) of Ven plus carfilzomib (K) and dexamethasone (d) in RRMM showed an overall response rate (ORR) of 80%, and ORR was higher in patients (pts) who were t(11;14)+ vs t(11;14)– (92 vs 75%; Costa, Blood Adv. 2021;5:3748). Here, we report initial safety and efficacy data in patients with t(11;14)+ RRMM treated with Ven (400 or 800 mg) combined with K (70 mg/m^2) and d (Ven400Kd or Ven800Kd) vs Kd alone in the dose-finding and randomized parts of the study. **Methods:** Pts with t(11;14)+ RRMM were randomized 5:3:5 to receive K (70 mg/m^2 weekly) and d (40 mg) plus daily Ven (Ven400Kd or Ven800Kd), or Kd alone. Pts in the randomized part had ≥1 prior line of therapy (LOT); pts in dose finding had 1–3 prior LOT. Primary objectives of the randomized part were to assess safety and efficacy. Secondary objectives were to assess progression-free survival (PFS), overall survival (OS), time to response (TTR), time to progression (TTP), and duration of response (DOR). Efficacy was analyzed in pts randomized to Ven400Kd, enrolled during dose finding or randomized to Ven800Kd, and randomized to Kd. Safety was analyzed in those who received ≥1 dose of study treatment. **Results:** At the 19 Jan 2023 cutoff, 48 randomized pts and 8 pts from dose finding were included (Ven400Kd, n=17; Ven800Kd, n=20; Kd, n=19); 1 pt in the Kd group was not treated. Pts had median age of 70.5–73 years, median 2 prior LOT, and had prior exposure to proteasome inhibitors (89–94%), immunomodulatory drugs (85–89%), and anti-CD38 mAb (24–47%). Treatment-emergent adverse events (TEAEs) occurring at ≥50% in any group (Ven400Kd vs Ven800Kd vs Kd) were diarrhea (65 vs 75 vs 6%), nausea (53 vs 55 vs 28%), fatigue (35 vs 50 vs 22%), and vomiting (0 vs 50 vs 11%). Grade ≥3 TEAEs occurred in 88, 85, and 72% of pts. Grade ≥3 TEAEs occurring at ≥20% in any group were lymphopenia (18 vs 30 vs 6%), neutropenia (12 vs 25 vs 11%), and hypertension (24 vs 15 vs 17%). Few Grade ≥3 cardiac disorders occurred (0 vs 5 vs 6%). Grade ≥3 infection rates were higher in the VenKd groups vs Kd (29 vs 20 vs 11%). At median follow-ups (range) of 16.8 (5.8–30.8), 21.1 (2.2–65.8), and 11.5 (0.0–28.3) months in the Ven400Kd, Ven800Kd, and Kd groups, respectively, corresponding ORRs (95% CI) were 94% (71–100), 95% (75–100), and 58% (34–80). Complete response (CR)/stringent CR rates were 29, 50, and 11%, respectively. Median TTR was 1.0, 1.0, and 2.4 months. 12-month PFS estimates were 67, 85, and 79%, with median PFS of 42.4 months (hazard ratio vs Kd=0.613 [95% CI, 0.153–2.456]) in the Ven800Kd group and not reached (NR) in the Ven400Kd and Kd groups. Medians for OS, TTP, and DOR were NR in any group. More mature data will be presented. **Conclusions:** Treatment with VenKd was well tolerated and produced favorable responses in >90% of pts with t(11;14)+ RRMM. Enrollment is ongoing.

Introduction: Although proteasome inhibitors (PIs) have transformed management of multiple myeloma (MM), drug resistance emerges through induction of the aggresome & autophagy pathway as a compensatory protein clearance mechanism. Accordingly, autophagy inhibitors used in association to conventional anti-MM drugs might enforce the effect against resistant MM cells and render autophagy a new therapeutic target.

that high expression of a part of these genes, including RNA-binding protein 39 (RBM39), are significantly associated with poor prognosis. We confirmed that RBM39 is indispensable for the MM cells by CRISPR/Cas9-mediated knockout and pharmacological protein degradation. **Conclusions:** We achieved a complete view of MM diversity that was not limited by cell surface antigens or transcriptome characteristics by using repertoire clonality. Our results highlight a novel subpopulation as a candidate therapeutic target for cure.

Critical roles of CRIP1 in promoting cell survival and bortezomib resistance by enhancing proteasome activity and autophagy in multiple myeloma

Zhen Yu[1], Peixia Tang[1], Zhenshu Xu[2], Mu Hao[1], Lugui Qiu[1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin 300020, China.; [2]Hematology Department Fujian Medical University Union Hospital, Fujian Institute of Hematology

Introduction: Although proteasome inhibitors (PIs) have transformed management of multiple myeloma (MM), drug resistance emerges through induction of the aggresome & autophagy pathway as a compensatory protein clearance mechanism. Accordingly, autophagy inhibitors used in association to conventional anti-MM drugs might enforce the effect against resistant MM cells and render autophagy a new therapeutic target.

Our previous study identified that CRIP1 was a high-risk gene that overexpressed in drug-resistance MM cells in post-treatment patient samples. However, the molecular mechanism of CRIP1 in myelomagenesis has not been fully understood. In this study, we evaluated the mechanism of CRIP1-mediated PIs resistance and MM cell aggressive proliferation. **Methods:** An inducible CRIP1-shRNA vector and CRIP1 overexpress vector were constructed to explore the role of CRIP1 in MM. Co-IP(Co-Immunoprecipitation) with TAP/MS (Tandem affinity purification/Mass spectrum) was performed to detect the binding of USP7, CRIP1 and PA200. Myeloma xenograft model was used to determine the role of CRIP1 to promote proliferation of MM cells and induce BTZ resistance in vivo. **Results:** Our data showed that CRIP1 was overexpressed in MM cells especially in patients with RRMM (relapsed/refractory MM). CRIP1 overexpression is linked to inferior outcome in patients with MM even those undergoing bortezomib (BTZ) treatment. CRIP1 promoted MM cell proliferation, invasion and decreased PIs sensitivity in MM cells. More important, CRIP1 overexpression stabilized PA200 and against PIs induced MM cell apoptosis by enhancing the proteasome activity and autophagy. Co-IP and TAPMS analysis indicated that CRIP1 promoted the deubiquitination and stabilization of PA200 by binding with USP7. Strikingly, our study elucidated for the first time that CRIP1 and PA200 were both the substrates of USP7. CRIP1 worked as a scaffold protein and played critical roles in BTZ resistance by forming the complex with USP7 and PA200. In vitro and in vivo studies further confirmed that the USP7 or PSME4 inhibition reduces CRIP1 induced BTZ - resistance in MM. **Conclusions:** In summary, CRIP1 was overexpressed in MM cells and correlated with inferior outcome of MM patients. CRIP1 induced drug resistance to proteasome inhibitors by promoting proteasome activity and autophagy in MM. CRIP1 promoted PA200 bound with USP7 through facilitating proteasome activity and autophagy and induced the BTZ resistance of MM cells. Blocking CRIP1/USP7/PA200 signal pathway would be an ideal strategy for MM therapy which can suppress proteasome activity and autophagy simultaneously.

Efficacy of bispecific antibodies in the treatment of extramedullary disease and high risk cytogenetics in relapsed multiple myeloma: a systematic review

Charan Vegivinti[1,2], Jaison Lawrence Alexander Santhi[3], Lawrence Liu[4], M Bakri Hammami[1,2], Rahul Thakur[1], Ananta Ghimire[5], Nagarathna Poojary[5], Murali Mohan Reddy Gopireddy[5], Anusha Manoj Kallamvalappil[6], Sahas Reddy Jitta[7], Nikita Chintapally[8], Nishi Shah[9,2], Murali Janakiram[4]

[1]Jacobi Medical Center; [2]Albert Einstein College of Medicine; [3]Government Sivagangai Medical College; [4]City of Hope National Comprehensive Cancer Center; [5]coGuide Academy; [6]Phoenix Hospital; [7]Mercy Hospital St louis Missouri; [8]MedStar Washington Hospital Center; [9]Montefiore Medical Center and Albert Einstein College of Medicine

Introduction: Bispecific antibodies (BsAbs) are effective treatments for relapsed multiple myeloma (MM). The purpose of this systematic review is to determine the efficacy of BsAbs in the management of extramedullary disease (EMD) and high risk cytogenetic abnormalities (HRCAs) in relapsed MM. **Methods:** A systematic literature search was conducted to identify clinical trials that investigated BsAbs in MM using the PubMed database and ASH-submitted abstracts using search terms (bispecific antibodies) AND (multiple myeloma). Our search on PubMed yielded 263 studies, of which 7 were clinical trials; of these, 5 were included, and 6 ASH abstracts were included. Cochrane-Q test and I^2 statistic were used to assess the statistical heterogenicity. A fixed effect model was used for low statistical heterogeneity ($P > 0.05$ in Cochrane-Q test and I^2 50%). Categorical outcomes were summarized by pooled proportion with 95% CI. **Results:** Overall response rates (ORRs) of the entire cohort were reported in 660 patients across 9 studies. The ORRs for EMD and HRCAs were reported in 3 (n=78) and 4 (n=100) studies, respectively. The ORR of the entire cohort was 0.65 [95% CI; 0.57; 0.74). The ORR of each BsAb was 0.70 (0.51-0.85; Chari et al, 2022) for talquetamab, 0.63 (0.55-0.70; Moreau et al, 2022) for teclistamab, and 0.61 (0.52-0.70; Bahlis et al, 2022) for elranatamab. The ORRs in MM with EMD and HRCAs with 95% CI were 0.38 [0.28; 0.49] and 0.60 [0.51; 0.70], respectively. Among the studies that reported the ORR in EMD, talquetamab (Chari et al, 2022) has the highest ORR of 0.45 (0.17; 0.77), followed by elranatamab (Bahlis et al, 2022) of 0.38 (0.23; 0.55), and teclistamab (Moreau el al, 2022) of 0.36 (0.19; 0.56). There is no significant difference in the ORR between the drugs with respect to EMD status. In studies that reported the ORR in HRCAs, talquetamab (Chari et al, 2022) had an ORR of 0.67 (0.17; 0.77) followed by teclistamab (Moreau el al, 2022) of 0.61 (0.43; 0.76), and elranatamab (Bahlis et al, 2022) of 0.55 (0.36; 0.73). Similarly, there is no significant difference in the ORR between the drugs with respect to HRCA status. The above results demonstrate that ORR in EMD is lower when compared to the entire cohort. **Conclusions:** Despite 11 clinical trials done with bispecific antibodies only 4 had reported EMD responses. This needs to be improved and clinical trials should report EMD responses distinctly as it directly informs clinical decisions. EMD responses are significantly lower than the full cohort ORR however it is encouraging that responses to high risk multiple myeloma (HRMM) closely approximate ORR of these agents. Further analysis is needed to see whether ORR and PFS correlate for HRMM. Evidence was insufficient to establish the relative superiority of one BsAb over another with EMD and combination therapies should be explored for EMD in myeloma.

The ORRs in MM with EMD and HRCAs with 95% CI were 0.38 [0.28; 0.49] and 0.60 [0.51; 0.70], respectively. Among the studies that reported the ORR in EMD, talquetamab (Chari et al, 2022) has the highest ORR of 0.45 (0.17; 0.77), followed by elranatamab (Bahlis et al, 2022) of 0.38 (0.23; 0.55), and teclistamab (Moreau el al, 2022) of 0.36 (0.19; 0.56). There is no significant difference in the ORR between the drugs with respect to EMD status. In studies that reported the ORR in HRCAs, talquetamab (Chari et al, 2022) had an ORR of 0.67 (0.17; 0.77) followed by teclistamab (Moreau el al, 2022) of 0.61 (0.43; 0.76), and elranatamab (Bahlis et al, 2022) of 0.55 (0.36; 0.73). Similarly, there is no significant difference in the ORR between the drugs with respect to HRCA status. The above results demonstrate that ORR in EMD is lower when compared to the entire cohort. **Conclusions:** Despite 11 clinical trials done with bispecific antibodies only 4 had reported EMD responses. This needs to be improved and clinical trials should report EMD responses distinctly as it directly informs clinical decisions. EMD responses are significantly lower than the full cohort ORR however it is encouraging that responses to high risk multiple myeloma (HRMM) closely approximate ORR of these agents. Further analysis is needed to see whether ORR and PFS correlate for HRMM. Evidence was insufficient to establish the relative superiority of one BsAb over another with EMD and combination therapies should be explored for EMD in myeloma.

Introduction: Immunotherapies have shown promise in treating MM, although this has been limited to relapsed and refractory MM. However, their application is limited by short remission, potential toxicity, and genomic heterogeneity. Here, we used genomic subgroups and high-risk markers to identify additional potential therapeutic targets with low predicted toxicity and high specificity to MM and genomic subgroups. **Methods:** RNA-seq data from 754 newly diagnosed MM (NDMM) and 98 relapsed and refractory MM (RRMM) samples with genomic annotation from the CoMMpass study were utilized. 32 NDMM and 43 RRMM in-house samples were used as validation. Genes with high surface potential were prioritized by annotations from 5 databases and annotation from the Human Protein Atlas was used to evaluate off-target toxicity. Candidates were further filtered to have high surface potential (>3 databases), low toxicity (normalized TPM>50 in 3). Candidates were identified at both the population and cytogenetic subgroup levels. **Results:** We identified 847 genes with high cell surface potential, of which 599 had low predicted off-target toxicity. 48 genes with high expression were identified as candidates in both the NDMM and RRMM population, all of which were validated with consistently high expression in the validation set. They included established targets such as SLAMF7/CD319, TNFRSF17/BCMA, GPRC5D, CD38, and FCRL5/FcRH5 as well as novel targets such as EVI2B, CD53, CD79A, CD79B, and CD48. High expression of CD53 and CD48 was also associated with poor progression-free survival with quartile analysis (p=0.03, p=0.01, logrank test). By splitting the population into cytogenetic subgroups 25 more candidates were identified, including significantly upregulated ROBO3 in t(4;14), SPN in t(14;16),t(14;20) and t(4;14) and MS4A1/CD20 in t(11;14) and t(14;16). SPN expression was significantly associated with overall survival in the three subgroups (p=0.0005, logrank test). 11 unique candidates were identified for other high-risk subgroups including 1q amp, biallelic TP53, and t(MYC). Some candidates were also associated with high-risk subgroups such as GPRC5D, IL6R and SPN which showed significantly elevated expression with increasing copies of 1q (p< 0.001, p< 0.001, p< 0.04, respectively). Using the DepMap database, IL6R was essential in the 1q-gained cell-line OCI-MY7 indicating that immune escape from this target may be difficult in some patients. **Conclusions:** Our studies demonstrated the existence of novel increased expression of genes encoding surface proteins in NDMM patient samples that maintained their expression levels or increased when being exposed to existing standard of care in MM. In some instances, these genes associate with existing cytogenetic subgroups and may serve as novel proteins that can be further targeted by immune-related therapies.

Introduction: Multiple myeloma (MM) is the second most common hematological malignancy. It is generally believed that MM cells develop from either B cells or plasma cells differentiated from hematopoietic stem cells (HSCs) in the bone marrow (BM). However, the nature of the earliest precursors of MM cells is still poorly defined. **Methods:** Screening the cellular origin of important genetic variation in MM patients and the key factor in cell subsets using scRNA-seq and scATAC-seq combined plasma cell differentiation. By using FISH and scPCR technology to verify the important genetic variation and differential genes of MM cell origin. Gene editing technology and adoptive B cell transplantation mouse model to verify the malignant transformation effect of screening key factor. **Results:** Firstly, we sorted HSCs, B cells and plasma cell of new diagnosis MM for scRNA-seq and scATAC-seq sequencing. Principal component analysis revealed the number of B cells declined and abnormal proportion. Further time pseudotime analysis found that MM patients with abnormal differentiation compared with the healthy donor, and "memory B" like subgroups had the potential to differentiate into plasma cells. By using inferCNV analysis, we found 1q amplification (1qAmp) could be detected in plasma cell and B cells but no HSCs. Furthermore we found that 1qAmp+ B cells have a CD24-FCRL5+phenotype. The use of FISH to validate clinical specimens further confirms this result. Finally, we sorted CD24-FCRL5+subgroups induction in vitro found that they had stronger differentiation potential of plasma cell. Suggesting that the CD24-FCRL5+ B cell subset is the cellular origin of 1qAmp. In vitro induced differentiation results display interference with FCRL5 expression inhibited B cell proliferation and plasma cell differentiation by used cas9 tag mice. The results were also confirmed by MM patients. The adoptive B cell transplantation by Vκmyc mice confirmed that over expression of FCRL5 promotes B cell malignant transformation and bone destruction. Further omics data analysis found that the open region of FCRL5 chromatin had SPI1 binding site, and FCRL5 upregulated the expression of proliferation related gene MCL1 and B cell differentiation gene IRF4. CHIP qPCR verified that SPI1 directly bound to the promoter region of MCL1 and IRF4. It is suggested that FCRL5 can promote B cell malignancy by recruiting SPI1 and regulating MCL1 and IRF4. **Conclusions:** Evidence from our previous study has demonstrated that the 1q amplification,

Introduction: While anti-BCMA chimeric antigen receptor T-cell therapy (CART) have proven safe and efficient in multiple myeloma (MM), its application to AL amyloidosis (AL), has been restricted, due to the frailty of this population and rarity of disease. HBI0101 therapy is a novel anti-BCMA CAR T-based therapy developed at Hadassah Medical Center for MM treatment. In a phase Ia/b study (NCT04720313), HBI0101 has demonstrated manageable safety with therapeutic efficacy in over 50 MM patients. Although BCMA targeting in AL has been questioned because of relatively low expression of this antigen on AL plasma cells (PC), we have previously reported that this level of expression is sufficient to enable PC eradication by HBI0101 CART ex vivo. Based on this observation, we have included 8 AL patients in our study, which represent the largest cohort of AL treated with BCMA-CART reported so far. **Methods:** Eight AL patients with relapsed/refractory disease were included, with a median of 6 prior lines of therapy (range: 3-10), all resistant to their last line. Six patients were penta-refractory, and five were resistant to belantamab. Seven of eight had cardiac involvement, including 4 with MAYO-stage IIIa/IIIb. The patients were treated within the following cohorts: 1 received $150x10^6$ CART cells, 2 received $450x10^6$ and 5 received $800x10^6$. Two of the patients were treated on a compassionate basis due to concomitant myelodysplastic syndrome (MDS) / ECOG 4 performance status. **Results:** Adverse events (AEs) were manageable, with cytokine-released syndrome (CRS) observed in 6/8 (grade 1-2- 4 patients; grade 3 - 2 patients). Hematologic AEs included: grade 3-4 neutropenia in 5/8, Grade 2-3 anemia in 2 patients, and in one case worsening to grade 4 of pre-existing thrombocytopenia. Two patients developed initial AL related organ deterioration, subsequently resolved. None of the patients developed immune effector cell-associated neurotoxicity syndrome (ICANs). There were no treatment-related deaths. HBI0101 therapy induced remarkable responses in these 8 heavily pretreated AL patients, achieving overall response rate of 100%, including a fast and efficient complete response in 5 patients, a very good partial response in 2, and a partial response in 1 patient. Minimal residual disease (MRD) negativity based on flow cytometry 10^{-5} was achieved in 5/8. The hematologic responses translated to clinical improvement in all patients, while 6/8 thus far met the official criteria for organ responses. With a median follow-up that is still short (7.3 months (m), range: 2.5-16.5), the median duration of response thus far is 5m (range: 2.5-16.5). **Conclusions:** In the largest cohort of AL patients reported to date, we demonstrated acceptable toxicity in this frail population, and remarkable efficacy translating into organ responses. Our data suggests that BCMA-CART modality may become a powerful clinical tool to improve organ function and survival even in advanced AL patients.

Introduction: Multiple Myeloma (MM) develops from precursors Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smoldering Multiple Myeloma (SMM). Bone marrow (BM) biopsies are not routine in precursor disease management and only few proteins within peripheral blood (PB) suggest progressive disease. PB proteome profiling may better help track disease; however, the dynamic range of the plasma proteome has limited detection depth for MS-based proteomics without depleting abundant proteins and fractionating the samples after digestion to peptides. We perform the first comprehensive plasma proteomic profiling study using advanced multiplex immunoassays on patients across the MM disease continuum and sequential samples from progressive and stable disease. **Methods:** We performed plasma profiling for 3000 proteins using the Olink® Explore 3072 library and Proximity Extension Assay (PEA) technology. Proteins were recognized by multiplexed antibodies labelled with DNA oligonucleotides that upon binding come into proximity, hybridize, and are extended to generate a unique sequence for protein identification with sequencing. We profiled 423 plasma samples from 348 individuals, including healthy controls (n=58), MGUS (n=67), SMM (n=179), MM (n=44), as well as sequential samples from patients with progressive (n=27) and stable disease with matched clinical follow-up time. Precursor defined samples from progressors range 1.03-

which is one of the most common cytogenetic abnormalities of MM, is detected in CD24-FCRL5+B cell sub-population by single-cell omics. Interestingly, FCRL5 drives MM malignant transformation through the promotive process of B cell proliferation and plasma cell differentiation.Our research will not only provide novel insights for the origin and mechanism of MM with different genetic events, but also provide a new intervention strategy for refractory and relapsed from the perspective of cell origin of MM.

Introduction: Multiple Myeloma (MM) develops from precursors Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smoldering Multiple Myeloma (SMM). Bone marrow (BM) biopsies are not routine in precursor disease management and only few proteins within peripheral blood (PB) suggest progressive disease. PB proteome profiling may better help track disease; however, the dynamic range of the plasma proteome has limited detection depth for MS-based proteomics without depleting abundant proteins and fractionating the samples after digestion to peptides. We perform the first comprehensive plasma proteomic profiling study using advanced multiplex immunoassays on patients across the MM disease continuum and sequential samples from progressive and stable disease. **Methods:** We performed plasma profiling for 3000 proteins using the Olink® Explore 3072 library and Proximity Extension Assay (PEA) technology. Proteins were recognized by multiplexed antibodies labelled with DNA oligonucleotides that upon binding come into proximity, hybridize, and are extended to generate a unique sequence for protein identification with sequencing. We profiled 423 plasma samples from 348 individuals, including healthy controls (n=58), MGUS (n=67), SMM (n=179), MM (n=44), as well as sequential samples from patients with progressive (n=27) and stable disease with matched clinical follow-up time. Precursor defined samples from progressors range 1.03-

5.88yrs prior to diagnosis, with a median clinical follow-up time of 7.05yrs. T-tests, ANOVAs, and a linear mixed effect model identified proteins across disease stages, progression status, and time with results adjusted for multiple testing using the Benjamini-Hochberg Method. **Results:** We captured circulating levels of proteins highly expressed on the surface of plasma cells, including CD38, SDC1, BCMA and SLAMF7, highlighting the ability of PEA technology to detect clinically relevant therapeutic targets. We identified proteins that significantly discriminated MGUS, SMM, and NDMM from healthy donors (n=222, 423, 494). Top classifiers included proinflammatory cytokines IL1, IL5, IL6, IL16, and IL18 which are known to create a BM environment that promotes malignant cell development by suppressing the microenvironment, promoting cellular adhesion, or increasing angiogenesis. Consistent with previous findings, baseline BCMA levels were significantly elevated in progressors vs. non-progressors, further supporting the potential utility of BCMA measurements for disease monitoring. Four novel proteins vital for calcium homeostasis and integrin-mediated cell adhesion significantly increased from healthy to MM and in progressors vs. non-progressors, nominating these proteins as candidate biomarkers of high-risk disease. **Conclusions:** We performed the most comprehensive plasma proteomics study to date on MM disease stages and identified candidate high-risk disease biomarkers. Additional studies are underway to validate candidates and integrate proteins into risk stratification models.

Introduction: Current evidence from retrospective studies supports serum(s)BCMA as a novel biomarker in the diagnosis, prognosis, response and surveillance in myeloma precursor disease (MPD): monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma (SMM). Independent prospective validation of sBCMA is essential. We analyzed prospectively collected serum samples of MPD patients enrolled on clinical studies. **Methods:** A total of 730 samples belonging to 187 patients were included in the study [624 samples from 150 patients in ORIGIN (Observational prospective Research study In monoclonal Gammopathies leading to myeloma NCT02726750); 26 samples from 13 patients with int. and high-risk SMM treated with pembrolizumab (NCT02603887) and 80 samples from 24 high-risk SMM patients in ISAMAR treated with isatuximab (ISA) (NCT02960555)]. sBCMA levels were measured in triplicate by enzyme-linked immunosorbent assay (ELISA) with human anti-BCMA/TNFRSF17 antibody from R&D systems (catalogue# DY193). SPSSv20 was used for statistical analysis, Mann-Whitney and ANOVA tests were used for non-parametric and parametric comparisons, respectively. **Results:** In ORIGIN, where untreated MGUS and/or SMM patients are followed prospectively until progression, the baseline sBCMA was significantly lower in MGUS vs SMM patients, [44.4 (IQR20.2-67.5) vs 59.4 (IQR34.3-120.8) ng/mL; p=0.006]. Longitudinal analysis showed that MGUS progressors (to SMM) (n=4) and SMM progressors (to MM) (n=13) had increasing sBCMA over time. The median sBCMA level at baseline, 1, and 3 years was 62.7 (IQR32.3 – 257.4), 81.3 (IQR27.9 – 239.2), and 139.5 (IQR123.9 – 139.5) ng/mL in MGUS-> SMM and 11.6 (2.6 – 45), 14.7 (4.3 – 61.3) and 27.8 (9.2 – 80.1) ng/mL in SMM->MM patients. MGUS patients (n=4) that progressed to SMM had a higher baseline sBCMA compared to non-progressor MGUS (n=54) [62.8 (IQR32.3 – 257.4) vs 43.3 (IQR15.7 – 64.3) ng/mL; p=0.236]. SMM patients who were treated with either pembrolizumab or ISA monotherapy on protocol and did not progress to MM (n=30) had lower baseline sBCMA compared to SMM progressors (n=7) (82.3 (IQR62.3 – 148.4) vs 176 (IQR101.7 – 330.7) ng/mL, p=0.078. In ISAMAR, sBCMA significantly decreased after treatment with ISA [baseline sBCMA 101.5 (IQR70.9 – 181.3)), after 30 cycles 14.9 (IQR9.3 – 69.3) ng/mL (p< 0.001)]. Correlation analysis of the serum paraprotein, i:u sFLC ratio and sBCMA throughout treatment showed significant reduction in all 3 parameters, but the slope of sBCMA decrease after treatment was significantly more pronounced than in the ratio or paraprotein (p< 0.001). **Conclusions:** sBCMA can be used for prediction of progression in MPD, where it may be an independent biomarker. Additionally, it may be used in response monitoring in MPD treatment allowing for faster assessment of response compared to traditional blood markers.

Diseases (NCT), Heidelberg, Germany; [8]Internal Medicine V, GMMG Study Group at University Hospital Heidelberg, Heidelberg, Germany

Introduction: The 20/2/20 model represents the prevailing standard of risk stratification for patients with smoldering multiple myeloma (SMM). This study aims at optimization of the 20/2/20 model by integrating evolving patterns of serum M-protein and involved serum free light chains (sFLC) as risk factors to more accurately identify patients at high risk who benefit from intensified monitoring or early therapeutic interventions. **Methods:** In this study we retrospectively included 339 patients diagnosed with SMM between 2010 and 2022, who met the 2014 IMWG diagnostic criteria (Rajkumar SV et al., Lancet Oncol., 2014). Through cutoff analyses, we defined evolving patterns of serum M-protein and involved sFLC. We then compared the performance of the Mayo2018 (BMPC >20%, M-protein > 2g/dl, FLCr >20; 0 points = low risk, 1 point = intermediate risk, ≥2 points = high risk; Lakshman A et al., BCJ, 2018), IMWG2020 (as Mayo2018 plus cytogenetic abnormalities (t(4;14), t(14;16), +1q21 and/or del13q); 0 points = low risk, 1 point = low intermediate risk, 2 points = intermediate risk, ≥3 points = high risk; Mateos MV et al., BCJ, 2020) and gradual IMWG2020 (gradual scoring system for M-protein, BMPC, FLCr and cytogenetic abnormalities; Mateos MV et al., BCJ, 2020) models enhanced by the dynamic risk factor "evolving M-protein and/or evolving sFLC" at one year from diagnosis to the respective standard models, using the c-index. **Results:** Based on optimal cut-point search and clinical applicability we defined the independent risk factors evolving M-protein as a >10% and >0,2g/dl increase in M-protein (49/222 patients (22%), HR=5.02, 95% CI [2.86;8.81], p25% and >50mg/l increase in involved sFLC (14/178 patients (8%), HR=3.66, 95% CI [1.60;8.38], p< 0.002) within one year from diagnosis. 58/179 patients (32%) had an evolving M-protein and/or evolving sFLC phenotype resulting in an increased risk of progression (HR=6.41, 95% CI [3.19;12.86], p< 0,001). At one year, 10 of 78 patients migrated from low to intermediate risk and 19 of 56 patients from intermediate to high risk in the Mayo2018 model when adding the evolving phenotype. At one year the combined risk factor „evolving M-protein and/or evolving sFLC" improved discrimination of the risk groups when added to the Mayo2018 model (c-statistics for static model: 0.750 vs. dynamic model: 0.783, p=0.165). Similarly, the IMWG2020 (static: 0.745 vs. dynamic: 0.805, p=0.014) and gradual IMWG2020 (static: 0.753 vs. dynamic: 0.828, p=0.005) models improved prognostication when expanded by dynamic M-protein/sFLC. **Conclusions:** Through integration of the dynamic risk factor "evolving M-protein and/or evolving sFLC" in the current risk stratification models of SMM, a crucial aspect of individual disease dynamics is taken into account. Our results show that the dynamic M-protein/sFLC models are superior to standard models. Independent validation of the analyses is in preparation.

Physical activity interventions to improve functional performance in patients with multiple myeloma

Jens Hillengass[1], Michaela Hillengass[1], Hillary Jacobson[1], Rikki Cannioto[1], Bryan Wittmeyer[1], Kirsten Moysich[1], Janine Joseph[1]

[1]Roswell Park Comprehensive Cancer Center

Introduction: Frailty is a frequent limitation for treatment and an adverse prognostic factor for multiple myeloma (MM) patients. In other settings, including oncology, physical exercise has been shown to be beneficial in improving patients' fitness. The IMWG has developed a frailty score based on patient-reported parameters. There are, however, only limited data on the safety and efficacy of physical exercise in MM to improve functional performance, especially with bone disease present. To address this gap in knowledge, we performed a two-arm non-randomized pilot exercise study in MM patients. **Methods:** Patients self-selected into one of two active interventions: a six-month, twice weekly, in person, supervised resistance training (strength training group, STG) and a six-month behavioral intervention using fitness trackers with regular remote prompts to motivate patients to achieve 150-300 active minutes per week (walking group, WG). The non-randomized design allowed patients to participate in the remote arm if they lived too far from the institution to attend regular training sessions or had COVID-19-related concerns. After informed consent, a patient's most recent imaging results were reviewed in an interdisciplinary tumor board; the patient was either cleared for participation, cleared with limitations, or declined for participation. Assessments of functional parameters occurred after three and six months of the intervention and three and six months after the intervention. **Results:** A total of 87 patients were informed of the trial. Of those, 44 patients refused to participate, mostly due to travel distance. Of the 43 enrolled patients, 24 chose the STG and 20 the WG. For different reasons, including the COVID-19 pandemic, five patients did not complete the trial. The tumor board recommended restrictions for seven patients (e.g., no overhead exercises; no impact exercises). There were no significant differences between the groups in terms of age, BMI, sex, race, ECOG performance status, disease response, disease status, and likelihood of completing the intervention. The combined study sample showed significant improvements in mobility (AM-PAC Basic Mobility Short Form, P< 0.01), six-minute walk test (6MWT, P< 0.01), 30-second sit-to-stand test (30STS, P< 0.01), timed up-and-go test (TUG, P< 0.01), and pain (visual analogue scale, P< 0.01) during the intervention. The 30STS remained significantly improved six months after the intervention, while the gains made in mobility and the TUG were partially lost. The gains in 6MWT and pain were not significantly changed after the intervention. **Conclusions:** In this pilot study, both the STG and the WG were feasible in patients with MM and led to improvements in relevant parameters of functional capacity. This work lays the foundation for future exercise interventions aimed at improving physical function and resilience in MM patients undergoing systemic treatment.

Introduction: The 20/2/20 model represents the prevailing standard of risk stratification for patients with smoldering multiple myeloma (SMM). This study aims at optimization of the 20/2/20 model by integrating evolving patterns of serum M-protein and involved serum free light chains (sFLC) as risk factors to more accurately identify patients at high risk who benefit from intensified monitoring or early therapeutic interventions. **Methods:** In this study we retrospectively included 339 patients diagnosed with SMM between 2010 and 2022, who met the 2014 IMWG diagnostic criteria (Rajkumar SV et al., Lancet Oncol., 2014). Through cutoff analyses, we defined evolving patterns of serum M-protein and involved sFLC. We then compared the performance of the Mayo2018 (BMPC >20%, M-protein > 2g/dl, FLCr >20; 0 points = low risk, 1 point = intermediate risk, ≥2 points = high risk; Lakshman A et al., BCJ, 2018), IMWG2020 (as Mayo2018 plus cytogenetic abnormalities (t(4;14), t(14;16), +1q21 and/or del13q); 0 points = low risk, 1 point = low intermediate risk, 2 points = intermediate risk, ≥3 points = high risk; Mateos MV et al., BCJ, 2020) and gradual IMWG2020 (gradual scoring system for M-protein, BMPC, FLCr and cytogenetic abnormalities; Mateos MV et al., BCJ, 2020) models enhanced by the dynamic risk factor "evolving M-protein and/or evolving sFLC" at one year from diagnosis to the respective standard models, using the c-index. **Results:** Based on optimal cut-point search and clinical applicability we defined the independent risk factors evolving M-protein as a >10% and >0,2g/dl increase in M-protein (49/222 patients (22%), HR=5.02, 95% CI [2.86;8.81], p25% and >50mg/l increase in involved sFLC (14/178 patients (8%), HR=3.66, 95% CI [1.60;8.38], p< 0.002) within one year from diagnosis. 58/179 patients (32%) had an evolving M-protein and/or evolving sFLC phenotype resulting in an increased risk of progression (HR=6.41, 95% CI [3.19;12.86], p< 0,001). At one year, 10 of 78 patients migrated from low to intermediate risk and 19 of 56 patients from intermediate to high risk in the Mayo2018 model when adding the evolving phenotype. At one year the combined risk factor „evolving M-protein and/or evolving sFLC" improved discrimination of the risk groups when added to the Mayo2018 model (c-statistics for static model: 0.750 vs. dynamic model: 0.783, p=0.165). Similarly, the IMWG2020 (static: 0.745 vs. dynamic: 0.805, p=0.014) and gradual IMWG2020 (static: 0.753 vs. dynamic: 0.828, p=0.005) models improved prognostication when expanded by dynamic M-protein/sFLC. **Conclusions:** Through integration of the dynamic risk factor "evolving M-protein and/or evolving sFLC" in the current risk stratification models of SMM, a crucial aspect of individual disease dynamics is taken into account. Our results show that the dynamic M-protein/sFLC models are superior to standard models. Independent validation of the analyses is in preparation.

Physical activity interventions to improve functional performance in patients with multiple myeloma

Jens Hillengass[1], Michaela Hillengass[1], Hillary Jacobson[1], Rikki Cannioto[1], Bryan Wittmeyer[1], Kirsten Moysich[1], Janine Joseph[1]

[1]Roswell Park Comprehensive Cancer Center

Introduction: Frailty is a frequent limitation for treatment and an adverse prognostic factor for multiple myeloma (MM) patients. In other settings, including oncology, physical exercise has been shown to be beneficial in improving patients' fitness. The IMWG has developed a frailty score based on patient-reported parameters. There are, however, only limited data on the safety and efficacy of physical exercise in MM to improve functional performance, especially with bone disease present. To address this gap in knowledge, we performed a two-arm non-randomized pilot exercise study in MM patients. **Methods:** Patients self-selected into one of two active interventions: a six-month, twice weekly, in person, supervised resistance training (strength training group, STG) and a six-month behavioral intervention using fitness trackers with regular remote prompts to motivate patients to achieve 150-300 active minutes per week (walking group, WG). The non-randomized design allowed patients to participate in the remote arm if they lived too far from the institution to attend regular training sessions or had COVID-19-related concerns. After informed consent, a patient's most recent imaging results were reviewed in an interdisciplinary tumor board; the patient was either cleared for participation, cleared with limitations, or declined for participation. Assessments of functional parameters occurred after three and six months of the intervention and three and six months after the intervention. **Results:** A total of 87 patients were informed of the trial. Of those, 44 patients refused to participate, mostly due to travel distance. Of the 43 enrolled patients, 24 chose the STG and 20 the WG. For different reasons, including the COVID-19 pandemic, five patients did not complete the trial. The tumor board recommended restrictions for seven patients (e.g., no overhead exercises; no impact exercises). There were no significant differences between the groups in terms of age, BMI, sex, race, ECOG performance status, disease response, disease status, and likelihood of completing the intervention. The combined study sample showed significant improvements in mobility (AM-PAC Basic Mobility Short Form, P< 0.01), six-minute walk test (6MWT, P< 0.01), 30-second sit-to-stand test (30STS, P< 0.01), timed up-and-go test (TUG, P< 0.01), and pain (visual analogue scale, P< 0.01) during the intervention. The 30STS remained significantly improved six months after the intervention, while the gains made in mobility and the TUG were partially lost. The gains in 6MWT and pain were not significantly changed after the intervention. **Conclusions:** In this pilot study, both the STG and the WG were feasible in patients with MM and led to improvements in relevant parameters of functional capacity. This work lays the foundation for future exercise interventions aimed at improving physical function and resilience in MM patients undergoing systemic treatment.

Introduction: Existing prognostic tools in multiple myeloma (MM) are designed specifically for clinicians and incorporate variables often unknown to MM patients (i.e. cytogenetics). Developing prognostic tools for patient use represents an important step in empowering patients to understand their prognosis and engage in shared decision making. Incorporating patient reported outcomes (PROs) may represent an opportunity for developing prognostic tools. The implementation of standardized cancer symptom assessment in clinics in Ontario, Canada since 2007 provides a unique opportunity to evaluate the prognostic ability of PROs. The objective of our study was to develop and validate a prognostic score for overall survival among transplant ineligible newly-diagnosed multiple myeloma (TI NDMM) patients incorporating PROs. **Methods:** This was a retrospective population-based, prognostic study using administrative data of all patients with TI NDMM in Ontario diagnosed between Jan 2007-Dec 2019. Index date was defined as one year following diagnosis to ensure only patients who did not receive a transplant in first line were included. Patients were randomly selected for model derivation (75%) and validation (25%). The derivation cohort was used to develop a multivariable Cox proportional hazards regression model with backward stepwise variable selection to predict the risk of death one year following index date. Baseline covariates at index date included demographic characteristics, clinical information, health care utilization, performance status, and PROs using the Edmonton Symptom Assessment Score, which measures 9 common cancer symptoms (e.g. pain, dyspnea) on a 10-point scale, where 7-10 is high burden. **Results:** There were 2356 TI NDMM patients identified. The median age was 75 with 42.2% female sex. The majority of patients (90.3%) had received a novel drug (IMID and/or PI) following diagnosis. The following factors were associated with an increased risk of death: age >80 (HR 1.11), previous history of congestive heart failure (HR 1.52), CRAB symptoms at diagnosis (HR 1.61), distance of >50 km to cancer center (HR 1.25), radiation received in the year prior (HR 1.48), no novel drugs received in the year prior (HR 1.36), emergency department (HR 1.55) or hospitalization (HR 2.13) in the prior 6-months, poor performance status (ECOG 3-4 HR 1.76) and increasing number of symptoms with high burden (HR 1.56) in the prior 6-months. Model discrimination in the validation cohort was high with C-statistic of 0.74, and calibration plots indicated strong agreement between observed and predicted risks. **Conclusions:** To our knowledge, this represents one of the first prognostic models developed in NDMM designed specifically for patients, using easily available variables that can be easily completed by patients themselves including PROs. This survival prognostic tool may improve communication regarding prognosis and shared decision making among older adults with MM and their health care providers.

Introduction: Randomized controlled trial data suggest that initiation of the more intensive triplet bortezomib-lenalidomide-dexamethasone (VRd) versus the less intensive doublet lenalidomide-dexamethasone (Rd) in patients newly diagnosed with multiple myeloma (MM) confers superior survival, but it is uncertain whether this survival benefit generalizes to frail patients treated in practice. **Methods:** We identified all patients newly diagnosed with MM who were initiated on either VRd or Rd in the national U.S. Veterans Affairs Healthcare System. We measured frailty using the electronic Veterans Affairs Frailty Index (VA-FI), which has been validated in veterans with and without cancer. Using established cutoffs, we identified patients who were moderate-severely frail (VA-FI ≥ 0.3), mildly frail (VA-FI 0.20-0.29), and nonfrail (VA-FI < 0.2). To reduce imbalance in potential confounding across treatment groups within frailty categories, we matched patients on MM stage and on a propensity score (1:1 nearest-neighbor with a caliper of 1%) that was modeled on the probability of being initially treated with VRd vs. Rd as a function of age, sociodemographics, comorbidity, and MM-specific covariates. We used Cox proportional hazards models to evaluate differences in mortality between veterans initiated on VRd and veterans initiated on Rd. Our secondary outcome was incidence of unplanned hospitalizations within one year of treatment initiation. **Results:** We identified 2573 patients newly diagnosed with MM who were initiated either on VRd (990) or Rd (1583), spanning years 2004-2020. After matching, patients who were moderate-severely frail were older than non-frail patients (median age 71.1 years vs. 67.6 years), had a higher prevalence of stage III MM (32.9% vs. 19.5%), and had a higher prevalence of myeloma-related health deficits. VRd vs. Rd was associated with lower mortality (HR = 0.81, 95% CI = 0.70 - 0.94) in the overall population. Moderate-severely

Introduction: Randomized controlled trial data suggest that initiation of the more intensive triplet bortezomib-lenalidomide-dexamethasone (VRd) versus the less intensive doublet lenalidomide-dexamethasone (Rd) in patients newly diagnosed with multiple myeloma (MM) confers superior survival, but it is uncertain whether this survival benefit generalizes to frail patients treated in practice. **Methods:** We identified all patients newly diagnosed with MM who were initiated on either VRd or Rd in the national U.S. Veterans Affairs Healthcare System. We measured frailty using the electronic Veterans Affairs Frailty Index (VA-FI), which has been validated in veterans with and without cancer. Using established cutoffs, we identified patients who were moderate-severely frail (VA-FI ≥ 0.3), mildly frail (VA-FI 0.20-0.29), and nonfrail (VA-FI < 0.2). To reduce imbalance in potential confounding across treatment groups within frailty categories, we matched patients on MM stage and on a propensity score (1:1 nearest-neighbor with a caliper of 1%) that was modeled on the probability of being initially treated with VRd vs. Rd as a function of age, sociodemographics, comorbidity, and MM-specific covariates. We used Cox proportional hazards models to evaluate differences in mortality between veterans initiated on VRd and veterans initiated on Rd. Our secondary outcome was incidence of unplanned hospitalizations within one year of treatment initiation. **Results:** We identified 2573 patients newly diagnosed with MM who were initiated either on VRd (990) or Rd (1583), spanning years 2004-2020. After matching, patients who were moderate-severely frail were older than non-frail patients (median age 71.1 years vs. 67.6 years), had a higher prevalence of stage III MM (32.9% vs. 19.5%), and had a higher prevalence of myeloma-related health deficits. VRd vs. Rd was associated with lower mortality (HR = 0.81, 95% CI = 0.70 - 0.94) in the overall population. Moderate-severely

frail patients demonstrated the strongest association between VRd vs. Rd and lower mortality (HR 0.74, 95% CI 0.56 - 0.97), whereas the association was weaker in mildly frail (HR 0.80, 95% CI 0.61 - 1.05) and nonfrail patients (HR 0.86, 95% CI 0.67 - 1.10). Although there was a modestly higher incidence of hospitalizations associated with VRd vs. Rd (incidence rate ratio [IRR] 1.22, 95% CI 1.1 - 1.34) in the overall population, this association weakened in moderate-severely frail patients (IRR 1.14, 95% CI 0.96 - 1.36). **Conclusions:** Our findings not only confirm the mortality benefit of VRd over Rd in U.S. veterans newly diagnosed with MM, but also suggest that this benefit is strongest in patients with the highest levels of frailty, countering historical recommendations to consider doublets in this population. These findings argue that a frail patient's cancer should be considered as a treatable cause of their frailty wherein more intensive treatment may be more effective.

Introduction: In patients (pts) with transplant-ineligible (TNE) NDMM, the immunomodulatory drug (IMiD®) lenalidomide forms a standard of care in combination with bortezomib (BORT) and dexamethasone (DEX). Iberdomide (IBER) is a novel, potent oral cereblon E3 ligase modulator (CELMoD™) with increased tumoricidal activity and immune-modulatory effects compared with IMiD agents. IBER has shown preclinical synergistic activity in combination with BORT, and IberVd has shown promising preliminary efficacy and safety in pts with relapsed/refractory MM in the ongoing phase 1/2 CC-220-MM-001 trial (NCT02773030). Here we report results from the dose-expansion cohort of IberVd in pts with TNE NDMM. **Methods:** Eligible pts had untreated symptomatic NDMM, no autologous stem cell transplant planned, nor ineligibility due to age or comorbidities. Oral IBER was given on days (D) 1–14 of each 21-d cycle in Cycle (C)1–8 and D1–21 of each 28-d cycle in ≥C9 in combination with subcutaneous BORT (starting at 1.3mg/m^2) on D1, 4, 8, and 11 of each 21-d cycle and oral DEX on D1, 2, 4, 5, 8, 9, 11, and 12 of each 21-d cycle in C1–8, and weekly in ≥C9 (20 or 10mg if >75 y of age in C1–8; 40 or 20mg if >75 y in ≥C9). Endpoints included preliminary efficacy and safety, pharmacokinetics, and minimal residual disease assessment. **Results:** As of March 3, 2023, 18 pts received IberVd (1 pt 1.0mg; 17 pts 1.6mg). Median age was 77.5 (57–84) y and 11 (61.1%) pts had high-risk cytogenetics. Median follow-up was 10.5 mo. Median treatment (Tx) duration was 48.4 (3.0–65.0) wk; 14 (77.8%) pts continued on Tx. Two pts withdrew from the study before completing a Tx cycle (1 lost to follow-up, 1 consent withdrawal); no pts withdrew due to IBER-related Tx-emergent adverse events (TEAEs). Grade (Gr) 3–4 TEAEs occurred in 70.6% pts; most common were neutropenia (17.6%) and infections (17.6%, including pneumonia [11.8%]). Two (11.8%) pts had Gr 3–4 peripheral neuropathy. Occurrence of other Gr 3–4 TEAEs was low. Eleven (64.7%) and 6 (35.3%) pts had IBER dose interruptions and reductions due to TEAEs, respectively. Overall response rate in the intention-to-treat population was 88.9% (95% CI, 65.3–98.6) with 4 stringent complete responses, 5 complete responses (CR), 5 very good partial responses (VGPR), and 2 partial responses; 2 pts were not evaluable. Overall, 9 (50.0%) pts achieved ≥CR, and 14 (77.8%) pts achieved ≥VGPR. Median time to response was 3.1 (3.0–17.0) wk; 68.6% of pts responded in < 6 wk. Pharmacodynamic data showed that IBER Tx led to robust substrate degradation (median >50% decrease) and immune stimulation (177% median increase in T-cell proliferation) when combined with Vd. **Conclusions:** IberVd showed high efficacy with deep, ongoing responses in this cohort of mostly older pts with TNE NDMM. The safety profile was manageable with no new safety signals, and no pts discontinued due to AEs. These data support further assessment of IBER combinations in the frontline setting.

These findings argue that a frail patient's cancer should be considered as a treatable cause of their frailty wherein more intensive treatment may be more effective.

Introduction: In patients (pts) with transplant-ineligible (TNE) NDMM, the immunomodulatory drug (IMiD®) lenalidomide forms a standard of care in combination with bortezomib (BORT) and dexamethasone (DEX). Iberdomide (IBER) is a novel, potent oral cereblon E3 ligase modulator (CELMoD™) with increased tumoricidal activity and immune-modulatory effects compared with IMiD agents. IBER has shown preclinical synergistic activity in combination with BORT, and IberVd has shown promising preliminary efficacy and safety in pts with relapsed/refractory MM in the ongoing phase 1/2 CC-220-MM-001 trial (NCT02773030). Here we report results from the dose-expansion cohort of IberVd in pts with TNE NDMM. **Methods:** Eligible pts had untreated symptomatic NDMM, no autologous stem cell transplant planned, nor ineligibility due to age or comorbidities. Oral IBER was given on days (D) 1–14 of each 21-d cycle in Cycle (C)1–8 and D1–21 of each 28-d cycle in ≥C9 in combination with subcutaneous BORT (starting at 1.3mg/m^2) on D1, 4, 8, and 11 of each 21-d cycle and oral DEX on D1, 2, 4, 5, 8, 9, 11, and 12 of each 21-d cycle in C1–8, and weekly in ≥C9 (20 or 10mg if >75 y of age in C1–8; 40 or 20mg if >75 y in ≥C9). Endpoints included preliminary efficacy and safety, pharmacokinetics, and minimal residual disease assessment. **Results:** As of March 3, 2023, 18 pts received IberVd (1 pt 1.0mg; 17 pts 1.6mg). Median age was 77.5 (57–84) y and 11 (61.1%) pts had high-risk cytogenetics. Median follow-up was 10.5 mo. Median treatment (Tx) duration was 48.4 (3.0–65.0) wk; 14 (77.8%) pts continued on Tx. Two pts withdrew from the study before completing a Tx cycle (1 lost to follow-up, 1 consent withdrawal); no pts withdrew due to IBER-related Tx-emergent adverse events (TEAEs). Grade (Gr) 3–4 TEAEs occurred in 70.6% pts; most common were neutropenia (17.6%) and infections (17.6%, including pneumonia [11.8%]). Two (11.8%) pts had Gr 3–4 peripheral neuropathy. Occurrence of other Gr 3–4 TEAEs was low. Eleven (64.7%) and 6 (35.3%) pts had IBER dose interruptions and reductions due to TEAEs, respectively. Overall response rate in the intention-to-treat population was 88.9% (95% CI, 65.3–98.6) with 4 stringent complete responses, 5 complete responses (CR), 5 very good partial responses (VGPR), and 2 partial responses; 2 pts were not evaluable. Overall, 9 (50.0%) pts achieved ≥CR, and 14 (77.8%) pts achieved ≥VGPR. Median time to response was 3.1 (3.0–17.0) wk; 68.6% of pts responded in < 6 wk. Pharmacodynamic data showed that IBER Tx led to robust substrate degradation (median >50% decrease) and immune stimulation (177% median increase in T-cell proliferation) when combined with Vd. **Conclusions:** IberVd showed high efficacy with deep, ongoing responses in this cohort of mostly older pts with TNE NDMM. The safety profile was manageable with no new safety signals, and no pts discontinued due to AEs. These data support further assessment of IBER combinations in the frontline setting.

Introduction: The use of high-dose chemotherapy followed by tandem autologous hematopoietic stem cell transplantation (auto-HSCT) has resulted in improved outcomes for patients with multiple myeloma (MM) While auto-HSCT is recognized as a standard of care for newly diagnosed transplant-eligible MM patients due to the improved long-term disease control and survival it provides, the exposure to high-dose chemotherapy is associated with an increased risk of second primary malignancies (SPMs), with a subset of SPMs categorized as second hematologic malignancies (SHM). Our study aims to provide the incidence of SPMs and SHMs on patients treated on TT I-IIIB based on long-term follow up **Methods:** Patients enrolled on total therapy I (NCT00580372), II (NCT00083551), IIIA (NCT00081939) and IIIB (NCT00572169) between 1989-2008 were included. Patients were treated at the University of Arkansas for Medical Sciences with combination-based chemotherapy, tandem auto-HSCT and maintenance therapy, and followed for development of SPMs and SHMs. **Results:** Among 1379 patients with newly diagnosed MM enrolled on four TT trials with a median follow up range of 15-25 years. SPMs (including SHMs and excluding non-melanoma skin cancer) occurred in 11.8% of patients of which 64.4% of SPMs were solid tumors (most common were prostate cancer (n=22), colorectal cancer (n=20), breast cancer (n=15), lung cancer (n=11), and bladder cancer (n=7). A total of 4.2% (n=58) of patients developed a SHM. SHMs include acute lymphoblastic leukemia (ALL) (n=4), acute myeloid leukemia (2.4%, n=33), myelodysplastic syndrome (0.7%, n=9), B-cell lymphoma (n=10), chronic myelomonocytic leukemia (n=1) and unspecified leukemia (n=1). Median time to first SHM in patients treated on TT I, TT II (+thalidomide), TT II (-thalidomide), TT IIIA, TTIIIB were 10.7, 7.67, 10.3, 5.56, and 6.23 years, respectively. No statistical difference between risk of SHMs and enrollment on specific clinical trial, was observed. However, all four ALL cases occurred in patients who were exposed to an immunomodulatory drug. No difference in SPMs were observed in patients treated on TT IIIB when compared to TT IIIA. **Conclusions:** The occurrence of SHMs in patients who were treated with tandem-autologous hematopoietic stem cell transplantation on earlier TT protocols and followed up for a median of more than 15 years was 4.2%. The risk of AML and/or MDS was 3.1%. Our long-term follow up indicates that the risk of developing SHMs is relatively low. With the improvement in long-term outcomes of MM patients it is important to consider the risk of developing various cancers and consider appropriate.

Introduction: While novel treatments have improved prognosis for most multiple myeloma (MM) patients (pts), survival remains poor for pts with high-risk (HR) disease. Achievement of minimal residual disease negativity (MRD–) correlates with better survival outcome and is particularly important for HR MM pts. The academic, multi-center phase II GMMG-CONCEPT trial (NCT03104842)

investigates the quadruplet isatuximab, carfilzomib, lenalidomide, and dexamethasone in newly diagnosed (ND) HR MM pts both transplant-eligible (TE) and ineligible (TNE). The planned interim analysis (IA) on the primary endpoint (EP) demonstrated MRD– after consolidation (CONS) with 67.7% and 54.2% for TE and TNE pts, respectively (Weisel, ASH 2022 #759). Here, we show data on sustained MRD– and progression-free survival (PFS). **Methods:** HR MM is defined by ISS stage 2 or 3 and any of del17p, t(4;14), t(14;16), or >3 copies 1q21 (amp1q21) as HR cytogenetic aberration (HRCA). All pts receive Isa-KRd induction, CONS, and Isa-KR maintenance. TE pts undergo high-dose therapy while TNE pts receive 2 extra cycles Isa-KRd. PFS is defined as combined EP of progressive disease or death, whichever occurs first. Data cutoff was on Dec. 1, 2022. **Results:** The IA population for the primary EP consists of 125 pts (99 TE-ITT-IA, 26 TNE-ITT) according to trial design; sustained MRD– and PFS is based on the full first cohort (127 TE, 26 TNE). Median age was 58 (range 35-73) and 74 (64-87) years for the TE-ITT-IA and TNE-ITT population. All pts had HR MM, del17p was the most common HRCA (n=44, 44.4% [TE]; n=11, 42.3% [TNE]), followed by t(4;14) (n=42, 42.4% [TE]; n=6, 23.1% [TNE]) and amp1q21 (n=31, 31.3% [TE]; n=14, 53.8% [TNE]). 31 (31.3%) of 91 evaluable TE and 7 (26.9%) of 24 evaluable TNE pts had ≥2 HRCA marking ultra-HR (30.4% overall). As reported, the CONCEPT trial significantly met its primary EP (MRD– rates after CONS: 67.7% in TE and 54.2% in TNE pts [NGF, 10-5]). Of 106 TE pts reaching MRD– at any timepoint (84.4%), it was sustained for ≥6 and ≥12 months in 90 (72.0%) and 80 (64.0%) pts. Results for 18 TNE pts with MRD– (69.2%) were slightly lower (susMRD–6mo: n=14, 53.8%; susMRD–12mo: n=12, 46.2%). With a median follow-up of 40 (33) months for TE (TNE) pts, the median PFS was not reached in either study arm. Exploratory PFS analysis showed 1-Y-PFS rates of 86.4% (95% CI: 80.5-92.6) for TE-ITT and 75.1% (59.7-94.5) for TNE-ITT pts. 2-Y-PFS rates were 78.3% (71.4-85.9) for TE-ITT and 62.6% (46.0-85.3) for TNE-ITT. Additional subgroup analyses showed that pts with elevated LDH or ≥2 HRCA or del17p were least likely to reach MRD– and had shortened PFS. Since the last report, no new safety signals occurred. **Conclusions:** Isa-KRd induces high rates of sustained MRD– in ND HRMM, translating into a median PFS that was not yet reached. Of the HR markers, elevated LDH, co-existence of ≥2 HRCA, and del17p are associated with lower MRD– and PFS rates, helping to identify the subgroups of HR MM at highest risk.

Introduction: Pomalidomide (POM) is an oral immunomodulatory drug with direct tumoricidal and immunomodulatory efficacy in lenalidomide (LEN)-refractory relapsed or refractory multiple myeloma (RRMM). POM, bortezomib (BORT), and dexamethasone (DEX; PVd) is a preferred option in patients (pts) who have received ≥1 prior therapies, including those who have received LEN and BORT. In the primary analysis of OPTIMISMM, pts had significantly prolonged median progression-free survival (PFS) with PVd versus BORT + DEX (Vd; 11.2 vs 7.1 months; HR 0.61; P< 0.0001), with a safety profile consistent with known adverse events (AEs) of the individual components. Here, we report results from the final overall survival (OS) analysis of pts treated with PVd versus Vd in OPTIMISMM. **Methods:** Eligible pts had a diagnosis of RRMM, received 1–3 prior lines of therapy (including ≥1 LEN-containing regimen), an ECOG performance status of ≤2, and documented disease progression during or after their last anti-myeloma therapy. OS was a secondary endpoint and was defined as time from randomization to death from any cause. OS was compared between arms using a log-rank test (with an overall 2-sided significance level of 5%) stratified by the 3 baseline factors used for randomization. Kaplan–Meier method was used to estimate the survival distribution functions for each arm. Median OS and 2-sided 95% CI for the median were estimated. A Cox proportional hazards model stratified by the 3 baseline factors was used to estimate HR and 95% CIs. **Results:** In the intent-to-treat population (N=559), 281 and 278 pts had ongoing PVd and Vd treatment, respectively; median duration of treatment was 41.2 and 21.4 months. In this final analysis of OS, the OS data were mature (overall event rate, 70.0%). With median follow-up of 64.5 months for surviving pts (data cutoff May 13, 2022), median OS was numerically longer with PVd versus Vd (35.6 vs 31.6 months; HR [95% CI], 0.94 [0.77–1.15]; P=0.571). Median PFS2 was longer in pts treated with PVd versus Vd (22.1 vs 16.9 months; HR [95% CI], 0.77 [0.64–0.94]; nominal P=0.008). Updated PFS and safety data were consistent with the primary analysis. Time to treatment failure was longer with PVd versus Vd (8.8 vs 4.6 months). The most common treatment-emergent AEs (TEAEs) with PVd were

investigates the quadruplet isatuximab, carfilzomib, lenalidomide, and dexamethasone in newly diagnosed (ND) HR MM pts both transplant-eligible (TE) and ineligible (TNE). The planned interim analysis (IA) on the primary endpoint (EP) demonstrated MRD– after consolidation (CONS) with 67.7% and 54.2% for TE and TNE pts, respectively (Weisel, ASH 2022 #759). Here, we show data on sustained MRD– and progression-free survival (PFS). **Methods:** HR MM is defined by ISS stage 2 or 3 and any of del17p, t(4;14), t(14;16), or >3 copies 1q21 (amp1q21) as HR cytogenetic aberration (HRCA). Introduction: Pomalidomide (POM) is an oral immunomodulatory drug with direct tumoricidal and immunomodulatory efficacy in lenalidomide (LEN)-refractory relapsed or refractory multiple myeloma (RRMM). POM, bortezomib (BORT), and dexamethasone (DEX; PVd) is a preferred option in patients (pts) who have received ≥1 prior therapies, including those who have received LEN and BORT. In the primary analysis of OPTIMISMM, pts had significantly prolonged median progression-free survival (PFS) with PVd versus BORT + DEX (Vd; 11.2 vs 7.1 months; HR 0.61; P< 0.0001), with a safety profile consistent with known adverse events (AEs) of the individual components. Here, we report results from the final overall survival (OS) analysis of pts treated with PVd versus Vd in OPTIMISMM. **Methods:** Eligible pts had a diagnosis of RRMM, received 1–3 prior lines of therapy (including ≥1 LEN-containing regimen), an ECOG performance status of ≤2, and documented disease progression during or after their last anti-myeloma therapy. OS was a secondary endpoint and was defined as time from randomization to death from any cause. OS was compared between arms using a log-rank test (with an overall 2-sided significance level of 5%) stratified by the 3 baseline factors used for randomization. Kaplan–Meier method was used to estimate the survival distribution functions for each arm. Median OS and 2-sided 95% CI for the median were estimated. A Cox proportional hazards model stratified by the 3 baseline factors was used to estimate HR and 95% CIs. **Results:** In the intent-to-treat population (N=559), 281 and 278 pts had ongoing PVd and Vd treatment, respectively; median duration of treatment was 41.2 and 21.4 months. In this final analysis of OS, the OS data were mature (overall event rate, 70.0%). With median follow-up of 64.5 months for surviving pts (data cutoff May 13, 2022), median OS was numerically longer with PVd versus Vd (35.6 vs 31.6 months; HR [95% CI], 0.94 [0.77–1.15]; P=0.571). Median PFS2 was longer in pts treated with PVd versus Vd (22.1 vs 16.9 months; HR [95% CI], 0.77 [0.64–0.94]; nominal P=0.008). Updated PFS and safety data were consistent with the primary analysis. Time to treatment failure was longer with PVd versus Vd (8.8 vs 4.6 months). The most common treatment-emergent AEs (TEAEs) with PVd were

neutropenia (54%), peripheral sensory neuropathy (48%), and thrombocytopenia (40%); with Vd these were thrombocytopenia (39%), peripheral sensory neuropathy (38%), and diarrhea (31%). The most common TEAE leading to treatment discontinuation was peripheral neuropathy (PVd, 11%; Vd, 8%); death occurred in 196 (71%) pts treated with PVd and 190 (70%) pts treated with Vd. **Conclusions:** These findings from OPTIMISMM showed a slight, nonsignificant trend towards improved OS with PVd versus Vd. PFS2 was also improved with PVd versus Vd. The safety profile of PVd was consistent with previous reports. These data support the use of PVd as an effective treatment option in pts with RRMM.

Introduction: CARTITUDE-4 is an open-label, randomized controlled trial (NCT04181827) comparing the CAR-T therapy ciltacabtagene autoleucel (cilta-cel) with physician's choice of standard of care (SOC) in lenalidomide (len)-refractory patients (pts) with multiple myeloma (MM). Cilta-cel significantly improved median progression-free survival (PFS) vs SOC (hazard ratio, 0.26 [95% CI, 0.18–0.38]; P< 0.0001) in the intent-to-treat population at a median follow-up of 15.9 months. Here, we report pharmacokinetic (PK) and correlative analyses in the 176 pts who received cilta-cel as study treatment. **Methods:** Eligible pts were len-refractory with 1–3 prior lines of therapy, including a proteasome inhibitor and an immunomodulatory drug and had an ECOG performance status score of ≤1. Pts randomized to cilta-cel underwent apheresis, received physician's choice of pomalidomide-based bridging treatment, and then 1 cilta-cel infusion (target dose 0.75×10^6 CAR+ viable T cells/kg) 5–7 d after lymphodepletion. The primary endpoint was PFS. PK was assessed by both CAR transgene levels and flow cytometry (CAR+ T cells per microliter in peripheral blood). Expression levels of BCMA on plasma cells in bone marrow aspirate (BMA) were assessed by flow cytometry. A ligand binding assay was used to quantify serum soluble BCMA (sBCMA). **Results:** As of Aug 2022, among the 176 pts who received cilta-cel as study treatment, CD3+CAR+ cells in blood peaked at median 13 d post infusion (mean, 1451 cells/μL; SD, 6169 cells/μL) and remained detectable for median 57 d (range, 13–631). Mean AUC00-28d of CD3+CAR+ cells in blood was 11,710 cells/μL (SD, 56,994 cells/μL). In 13 pts with progressive disease (PD) and available data, we did not observe a reappearance or re-expansion of CD3+CAR+ cells in blood at PD; CAR+ T cells were below the lower limit of quantification (LLOQ; 2 cells/mL) in all pts. sBCMA decreased following cilta-cel infusion in all patients, becoming undetectable (LLOQ, 0.25000 μg/L) at median day 56. At PD, results for sBCMA and proportion of BCMA+ MM cells in BMA were available for 3 and 6 pts respectively. After an initial decline following cilta-cel infusion, sBCMA levels either returned to or exceeded baseline levels at PD. Similar findings were observed in the 6 pts with available data on the proportion of BCMA+ MM cells in bone marrow. **Conclusions:** CAR transgene and cellular levels in CARTITUDE-4 were concordant with observations in CARTITUDE-1 and showed similar expansion and persistence profiles. Based on the samples available at data cut-off, sBCMA levels and proportion of BCMA+ MM cells return to levels at or above baseline at time of relapse, without reappearance or re-expansion of CD3+CAR+ cells in blood. Study follow-up is ongoing, and more samples may be available with additional follow-up. Understanding mechanisms of resistance is an area of interest which will ultimately assist with the sequencing of MM therapies.

Introduction: Daratumumab (Dara) is a therapeutic antibody against CD38, which triggers both direct and immune-mediated cytotoxicity in multiple myeloma (MM) cells. Although Dara combination therapies have high efficacy, relapse due to Dara resistance is common. **Methods:** To identify tumor-intrinsic genes involved in resistance to Dara, we performed two CRISPR knockout (KO) screens, and RNA-seq in KDM6A KO cells. **Results:** At the first screen, we found 433 genes that were positively correlated with MM cytotoxicity triggered by Dara and primary NK cells. 16 of these genes were also correlated with cytolytic activity in most of the 36 cancer types we analyzed in the TCGA database. Dara efficacy is closely associated with the expression of CD38, with nonresponders having lower CD38 expression. Therefore, our second screen used CRISPR to find genes whose KO caused the lowest expression of CD38 (bottom 5%). KDM6A was the top-ranked gene out of the set of overlapping genes from these two screens. We confirmed that KDM6A KO significantly decreased CD38 expression (>2 times, p< 0.01) and that re-introducing KDM6A into KDM6A KO cells restored the expression of CD38 and Dara-induced cytotoxicity. KDM6A encodes lysine-specific demethylase 6A, which demethylates lysine 27 of histone H3 (H3K27) to promote gene expression. In fact, when we compared the CD38 promoter area between KDM6A KO and control cells using ChIP-seq and ChIP qPCR, we found that the H3K27me3 level was higher in KDM6A KO cells. Conversely, the re-introduction of KDM6A into KDM6A-KO cells decreased the H3K27me3 level. Concordantly, Dara-resistant cell lines had lower CD38 expression and higher levels of H3K27me3 at the CD38 promoter. Interestingly, we found that CD38 overexpression only partially restored the sensitivity of KDM6A KO cells to Dara treatment, suggesting other mechanisms for KDM6A. We performed RNA-seq in KDM6A KO cells and found that CD48, an NK-activating ligand, was downregulated. Overexpression of CD48 in KDM6A KO cells significantly increased secretion of Granzyme B and Perforin by NK cells, restoring the activity of NK cells and re-sensitizing KDM6A KO cells to Dara treatment. These data suggest that KDM6A not only regulates CD38 expression but also NK cell activity by CD48 regulation, thereby modulating the efficacy of Dara. KDM6A acts to oppose the EZH2/PRC2 complex by demethylating H3K27me3, and we found that Tazemetostat (Taze), an FDA-approved EZH2 inhibitor, increased the expression of CD38 and CD48 at the protein, mRNA, and surface expression levels, especially in KDM6A-KO cells. Importantly, Taze also restored the sensitivity of KDM6A KO cells to Dara-mediated NK cell cytotoxicity. **Conclusions:** Taken together, our data reveal that KDM6A assists in Dara targeting by upregulating CD38 and in Dara cytotoxicity by modulating NK activity through CD48 regulation. By imitating its function using an FDA-approved inhibitor, we may overcome Dara resistance and improve patient outcomes in MM.

Introduction: CARTITUDE-4 is a global, open-label, randomized controlled trial (NCT04181827) comparing the chimeric antigen receptor (CAR)-T cell therapy ciltacabtagene autoleucel (cilta-cel) with physician's choice of standard of care (SOC; pomalidomide, bortezomib, and dexamethasone [PVd] or daratumumab, pomalidomide, and dexamethasone [DPd]) in lenalidomide (len)-refractory patients (pts) with multiple myeloma (MM). Cilta-cel significantly improved progression-free survival (PFS) vs SOC (median not reached [95% CI 22.8–not estimable] vs 11.8 months [mo] [95% CI, 9.7–13.8], hazard ratio (HR) 0.26 [95% CI, 0.18–0.38]; P< 0.0001) in the intent-to-treat (ITT) population. Here we report outcomes from prespecified subgroup analyses in the ITT population. **Methods:** Eligible pts were len-refractory with 1–3 prior lines of therapy (LOT), including a proteasome inhibitor and immunomodulatory drug, and ECOG performance status score of ≤1. Pts randomized to cilta-cel underwent apheresis, received physician's choice of PVd or DPd bridging treatment (tx), and then

Introduction: Daratumumab (Dara) is a therapeutic antibody against CD38, which triggers both direct and immune-mediated cytotoxicity in multiple myeloma (MM) cells. Although Dara combination therapies have high efficacy, relapse due to Dara resistance is common. **Methods:** To identify tumor-intrinsic genes involved in resistance to Dara, we performed two CRISPR knockout (KO) screens, and RNA-seq in KDM6A KO cells. **Results:** At the first screen, we found 433 genes that were positively correlated with MM cytotoxicity triggered by Dara and primary NK cells. 16 of these genes were also correlated with cytolytic activity in most of the 36 cancer types we analyzed in the TCGA database. Dara efficacy is closely associated with the expression of CD38, with nonresponders having lower CD38 expression. Therefore, our second screen used CRISPR to find genes whose KO caused the lowest expression of CD38 (bottom 5%). KDM6A was the top-ranked gene out of the set of overlapping genes from these two screens. We confirmed that KDM6A KO significantly decreased CD38 expression (>2 times, p< 0.01) and that re-introducing KDM6A into KDM6A KO cells restored the expression of CD38 and Dara-induced cytotoxicity. KDM6A encodes lysine-specific demethylase 6A, which demethylates lysine 27 of histone H3 (H3K27) to promote gene expression. In fact, when we compared the CD38 promoter area between KDM6A KO and control cells using ChIP-seq and ChIP qPCR, we found that the H3K27me3 level was higher in KDM6A KO cells. Conversely, the re-introduction of KDM6A into KDM6A-KO cells decreased the H3K27me3 level. Concordantly, Dara-resistant cell lines had lower CD38 expression and higher levels of H3K27me3 at the CD38 promoter. Interestingly, we found that CD38 overexpression only partially restored the sensitivity of KDM6A KO cells to Dara treatment, suggesting other mechanisms for KDM6A. We performed RNA-seq in KDM6A KO cells and found that CD48, an NK-activating ligand, was downregulated. Overexpression of CD48 in KDM6A KO cells significantly increased secretion of Granzyme B and Perforin by NK cells, restoring the activity of NK cells and re-sensitizing KDM6A KO cells to Dara treatment. These data suggest that KDM6A not only regulates CD38 expression but also NK cell activity by CD48 regulation, thereby modulating the efficacy of Dara. KDM6A acts to oppose the EZH2/PRC2 complex by demethylating H3K27me3, and we found that Tazemetostat (Taze), an FDA-approved EZH2 inhibitor, increased the expression of CD38 and CD48 at the protein, mRNA, and surface expression levels, especially in KDM6A-KO cells. Importantly, Taze also restored the sensitivity of KDM6A KO cells to Dara-mediated NK cell cytotoxicity. **Conclusions:** Taken together, our data reveal that KDM6A assists in Dara targeting by upregulating CD38 and in Dara cytotoxicity by modulating NK activity through CD48 regulation. By imitating its function using an FDA-approved inhibitor, we may overcome Dara resistance and improve patient outcomes in MM.

Introduction: CARTITUDE-4 is a global, open-label, randomized controlled trial (NCT04181827) comparing the chimeric antigen receptor (CAR)-T cell therapy ciltacabtagene autoleucel (cilta-cel) with physician's choice of standard of care (SOC; pomalidomide, bortezomib, and dexamethasone [PVd] or daratumumab, pomalidomide, and dexamethasone [DPd]) in lenalidomide (len)-refractory patients (pts) with multiple myeloma (MM). Cilta-cel significantly improved progression-free survival (PFS) vs SOC (median not reached [95% CI 22.8–not estimable] vs 11.8 months [mo] [95% CI, 9.7–13.8], hazard ratio (HR) 0.26 [95% CI, 0.18–0.38]; P< 0.0001) in the intent-to-treat (ITT) population. Here we report outcomes from prespecified subgroup analyses in the ITT population. **Methods:** Eligible pts were len-refractory with 1–3 prior lines of therapy (LOT), including a proteasome inhibitor and immunomodulatory drug, and ECOG performance status score of ≤1. Pts randomized to cilta-cel underwent apheresis, received physician's choice of PVd or DPd bridging treatment (tx), and then

1 cilta-cel infusion (target dose, 0.75×10^6 CAR+ viable T cells/kg) 5–7 days after start of lymphodepletion. Pts randomized to SOC received physician's choice of PVd or DPd until progression. Primary endpoint was PFS, analyzed using a weighted method to focus on PFS after the period during which both arms were on the same tx. Subgroup analyses of PFS was reported with HRs and 95% CIs. **Results:** Pts were randomized between July 2020 and November 2021. As of November 1, 2022, median follow-up was 15.9 mo (range, 0.1–27). 208 pts were randomized to cilta-cel (of whom 176 received cilta-cel) and 211 to SOC. Arms were balanced at baseline; 32.5% of pts had 1 prior LOT and 6.2% were ISS stage III. 61.2% of pts had high-risk cytogenetics (ie, del(17p), t(14;16), t(4;14) or gain/amp(1q)); 22.0% had ≥2 high-risk abnormalities. 18.9% had soft tissue plasmacytomas, 20.5% had bone marrow plasma cells ≥60%, and 15.0% of pts had triple-class refractory disease. 12.9% of pts received PVd; 87.1% received DPd. Cilta-cel significantly improved PFS vs SOC in all subgroups analyzed, including pts aged < 65 yrs, HR 0.24 (95% CI, 0.15–0.38), and 65–75 yrs, 0.34 (0.19–0.61); with 1 prior LOT, 0.35 (0.19–0.66); ISS stage III, 0.33 (0.11–0.95); ≥1 cytogenetic high-risk abnormality, 0.25 (0.16–0.38); ≥2 high-risk abnormalities, 0.33 (0.17–0.64); soft tissue plasmacytomas, 0.39 (0.21–0.75); bone marrow plasma cells ≥60%, 0.28 (0.14–0.59); triple-class refractory disease, 0.15 (0.05–0.39), as well as pts treated with PVd, 0.31 (0.13–0.72) and DPd, 0.26 (0.18–0.39). **Conclusions:** Cilta-cel significantly improved PFS across all analyzed subgroups of the ITT population, including by age, in those with high-risk features, after first relapse, and vs both SOC regimens. Benefit shown was similar to that seen in the overall ITT population, confirming efficacy of a single cilta-cel infusion in a range of clinically relevant MM subgroups.

Introduction: Isatuximab (Isa) is an anti-CD38 monoclonal antibody approved in combination with carfilzomib (K) and dexamethasone (d) for patients (pts) with relapsed multiple myeloma (MM) after ≥1 prior therapy, based on the primary progression-free survival (PFS) analysis of the Phase 3 IKEMA study (HR: 0.531; 99% CI: 0.318–0.889; one-sided p=0.0007; NCT03275285). At final PFS analysis 2 years later with a median follow-up of 43.96 months, the median PFS was reached — 35.65 mo (Isa-Kd) vs 19.15 mo (Kd). Here we report the final overall survival (OS) results from IKEMA planned 3 years after the primary PFS analysis. **Methods:** Pts with 1–3 prior lines of therapy were randomized 3:2 to receive Isa-Kd (n=179) or Kd (n=123). Treatment was given until progressive disease, unacceptable toxicity, or pt wish. Safety was assessed in all treated pts. **Results:** As of 7 February 2023 (cutoff), with a median follow-up of 56.61 mo, 42 (23.5%) and 7 (5.7%) pts in the Isa-Kd and Kd arms were still on treatment (tx); 81 (45.3%) and 66 (53.7%), respectively, discontinued due to progressive disease. Median tx duration was longer with Isa-Kd vs Kd (94.0 vs 61.9 weeks). A trend toward an OS benefit was observed with Isa-Kd vs Kd (median OS not reached [NR; 95% CI: 52.172–NR] vs 50.6 mo [95% CI: 38.932–NR]; HR: 0.855; 95% CI: 0.608–1.202; nominal one-sided p=0.1836). A sensitivity analysis censoring COVID-19 deaths showed consistent results (HR: 0.803; 95% CI: 0.564–1.142). Time to next tx (TTNT) was in favor of Isa-Kd (median 43.99 [95% CI: 31.31–NR] vs 25.0 [95% CI: 17.938–31.31] mo; HR: 0.583; 95% CI: 0.429–0.792; nominal one-sided p=0.0002), as was second progression-free survival (PFS2; median 47.18 [95% CI: 38.965–57.922] vs 32.36 [95% CI: 23.129–40.016] mo; HR: 0.663; 95% CI: 0.491–0.895; nominal one-sided p=0.0035). The difference between arms in median PFS2 (14.82 mo) remains very close to the difference in median PFS (16.50 mo). More pts in the Kd vs Isa-Kd arm received further anti-myeloma therapies that included those with novel mechanisms of action (MoA; 65.9% vs 49.7%) and further anti-CD38 agents (63.0% vs 29.2%). The safety profiles of both arms were comparable to those in the interim and final PFS analyses. Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in 84.2% (Isa-Kd) and 73.0% (Kd) of pts, while serious TEAEs occurred in 71.2% and 60.7% of pts. TEAEs leading to tx discontinuation occurred in 13.6% Isa-Kd and 18.0% Kd pts. Despite longer exposure, both arms had a similar incidence of cardiac failure (Isa-Kd: 8.5%; Kd: 8.2%). **Conclusions:** This final OS analysis shows a meaningful trend for OS benefit with Isa-Kd vs Kd despite subsequent tx with anti-CD38 agents, introduction of tx with novel MoA among further therapies, and the COVID-19 pandemic. Improvements in TTNT and PFS2 were observed, and sustained PFS benefit still observed at PFS2. The Isa-Kd safety profile

1 cilta-cel infusion (target dose, 0.75×10^6 CAR+ viable T cells/kg) 5–7 days after start of lymphodepletion. Pts randomized to SOC received physician's choice of PVd or DPd until progression. Introduction: MEZI is a novel, potent oral cereblon E3 ligase modulator (CELMoD™) with enhanced antimyeloma effects compared with immunomodulatory drugs (IMiDs®). In the phase 1/2 CC-92480-MM-002 trial (NCT03989414), MEZI showed promising efficacy and safety with DEX+BORT (MeziVd) and DEX+CFZ (MeziKd) in pts with RRMM. In phase 1, a 1.0mg dose plus BORT+DEX (MeziVd-1.0mg) was selected for further investigation. Here we report updated results from the MeziVd and MeziKd dose-escalation cohorts and the MeziVd-1.0mg dose-expansion cohort. **Methods:** Key eligibility criteria were: RRMM, 2–4 (MeziVd and MeziKd cohorts) or 1–3 (MeziVd-1.0mg cohort) prior regimens including lenalidomide (LEN), and documented progressive disease during or after last myeloma therapy. MEZI was given at escalating doses (0.3, 0.6, 1.0mg) or at 1.0mg on days (D)1–14 of each 21-D cycle with BORT+DEX, or at escalating doses on D1–21 of each 28-D cycle with CFZ+DEX. Primary objectives were to determine the recommended dose and regimen (dose-escalation cohorts) and to evaluate safety and efficacy. **Results:** As of March 20, 2023, 28 pts received MeziVd, 38 MeziVd-1.0mg, and 27 MeziKd. Across all cohorts, 65.8–88.9% pts were IMiD agent–refractory, 18.4–51.9% pts were proteasome inhibitor (PI)–refractory, and 36.8–74.1% pts were anti-CD38 monoclonal antibody (mAb)–refractory; median follow-up was 10.8–13.2 months. The most frequent grade 3–4 treatment-emergent adverse events (TEAEs) were neutropenia (35.7%) and thrombocytopenia (21.4%) with MeziVd; neutropenia (57.9%) and all infections (34.2%) with MeziVd-1.0mg; and neutropenia (40.7%) and all infections (29.6%) with MeziKd. Excluding all infections, grade 3–4 non-hematologic TEAEs were low. MEZI dose reductions due to TEAEs were needed in 7 (25.0%), 15 (39.5%), and 7 (25.9%) pts with MeziVd, MeziVd-1.0mg, and MeziKd, respectively. Overall response rate (ORR) was 75.0% with MeziVd (21/28); 84.2% with MeziVd-1.0mg (32/38); and 85.2% with MeziKd (23/27). In the MeziVd-1.0mg cohort, 2 pts were minimal residual disease–negative (10^{-4} threshold). In pts with prior LEN and anti-CD38 mAb exposure, ORR was 71.4% (10/14; MeziVd), 85.7% (12/14; MeziVd-1.0mg), and 86.4% (19/22; MeziKd). Median time to response was 1.38 (0.7–3.3), 0.89 (0.7–2.4), and 0.95 (0.9–5.1) months in the MeziVd, MeziVd-1.0mg, and MeziKd cohorts, respectively. Median duration of response was 10.4 and 11.9 months in the MeziVd and MeziKd cohorts and not reached in the MeziVd-1.0mg cohort. MEZI showed pharmacodynamic activity with BORT or CFZ at all doses tested, with 1.0mg inducing the greatest substrate degradation and T-cell proliferation. **Conclusions:** With longer follow-up, MeziVd and MeziKd continued to show promising efficacy at all dose levels tested with a manageable safety profile in pts with RRMM, consistent with previous reports. Dose optimization of MEZI+DEX in combination with PIs continues to be explored, and these data support further exploration in phase 3 studies.

Introduction: Tiragolumab (Tira) is a monoclonal antibody (mab) that targets TIGIT, a co-inhibitory receptor and immune checkpoint associated with T cell and natural killer cell (NK) dysfunction in cancer. Atezolizumab (Atezo) is a mab that targets the PD-1/PD-L1 axis, abundantly expressed immune checkpoints in Relapsed/Refractory (R/R) Multiple Myeloma (MM) patients (pts). Tira + Atezo administration is intended to reverse immunosuppressive functions of antigen presenting cells and regulatory T cells. Here we present biomarker data demonstrating pharmacodynamic modulation in a Phase Ia/Ib study (GO41036; NCT04045028) evaluating Tira alone (n=10), Tira with Daratumumab (Dara) (T+D) (n=11), or Tira with Dara and Atezo (T+D+A) (n=3) in R/R MM pts. **Methods:** Peripheral biomarkers were evaluated using whole blood flow cytometry, plasma cytokine, and soluble

was consistent with previous analyses, supporting it as a standard-of-care therapy for relapsed MM pts. Funding: Sanofi.

Introduction: MEZI is a novel, potent oral cereblon E3 ligase modulator (CELMoD™) with enhanced antimyeloma effects compared with immunomodulatory drugs (IMiDs®). In the phase 1/2 CC-92480-MM-002 trial (NCT03989414), MEZI showed promising efficacy and safety with DEX+BORT (MeziVd) and DEX+CFZ (MeziKd) in pts with RRMM. In phase 1, a 1.0mg dose plus BORT+DEX (MeziVd-1.0mg) was selected for further investigation. Here we report updated results from the MeziVd and MeziKd dose-escalation cohorts and the MeziVd-1.0mg dose-expansion cohort. **Methods:** Key eligibility criteria were: RRMM, 2–4 (MeziVd and MeziKd cohorts) or 1–3 (MeziVd-1.0mg cohort) prior regimens including lenalidomide (LEN), and documented progressive disease during or after last myeloma therapy. MEZI was given at escalating doses (0.3, 0.6, 1.0mg) or at 1.0mg on days (D)1–14 of each 21-D cycle with BORT+DEX, or at escalating doses on D1–21 of each 28-D cycle with CFZ+DEX. Primary objectives were to determine the recommended dose and regimen (dose-escalation cohorts) and to evaluate safety and efficacy. **Results:** As of March 20, 2023, 28 pts received MeziVd, 38 MeziVd-1.0mg, and 27 MeziKd. Across all cohorts, 65.8–88.9% pts were IMiD agent–refractory, 18.4–51.9% pts were proteasome inhibitor (PI)–refractory, and 36.8–74.1% pts were anti-CD38 monoclonal antibody (mAb)–refractory; median follow-up was 10.8–13.2 months. The most frequent grade 3–4 treatment-emergent adverse events (TEAEs) were neutropenia (35.7%) and thrombocytopenia (21.4%) with MeziVd; neutropenia (57.9%) and all infections (34.2%) with MeziVd-1.0mg; and neutropenia (40.7%) and all infections (29.6%) with MeziKd. Excluding all infections, grade 3–4 non-hematologic TEAEs were low. MEZI dose reductions due to TEAEs were needed in 7 (25.0%), 15 (39.5%), and 7 (25.9%) pts with MeziVd, MeziVd-1.0mg, and MeziKd, respectively. Overall response rate (ORR) was 75.0% with MeziVd (21/28); 84.2% with MeziVd-1.0mg (32/38); and 85.2% with MeziKd (23/27). In the MeziVd-1.0mg cohort, 2 pts were minimal residual disease–negative (10^{-4} threshold). In pts with prior LEN and anti-CD38 mAb exposure, ORR was 71.4% (10/14; MeziVd), 85.7% (12/14; MeziVd-1.0mg), and 86.4% (19/22; MeziKd). Median time to response was 1.38 (0.7–3.3), 0.89 (0.7–2.4), and 0.95 (0.9–5.1) months in the MeziVd, MeziVd-1.0mg, and MeziKd cohorts, respectively. Median duration of response was 10.4 and 11.9 months in the MeziVd and MeziKd cohorts and not reached in the MeziVd-1.0mg cohort. Introduction: Tiragolumab (Tira) is a monoclonal antibody (mab) that targets TIGIT, a co-inhibitory receptor and immune checkpoint associated with T cell and natural killer cell (NK) dysfunction in cancer. Atezolizumab (Atezo) is a mab that targets the PD-1/PD-L1 axis, abundantly expressed immune checkpoints in Relapsed/Refractory (R/R) Multiple Myeloma (MM) patients (pts). Tira + Atezo administration is intended to reverse immunosuppressive functions of antigen presenting cells and regulatory T cells. Here we present biomarker data demonstrating pharmacodynamic modulation in a Phase Ia/Ib study (GO41036; NCT04045028) evaluating Tira alone (n=10), Tira with Daratumumab (Dara) (T+D) (n=11), or Tira with Dara and Atezo (T+D+A) (n=3) in R/R MM pts. **Methods:** Peripheral biomarkers were evaluated using whole blood flow cytometry, plasma cytokine, and soluble

BCMA (sBCMA) by LC-MS/MS with immunoaffinity capture. Tumor biomarkers were assessed by flow cytometry using bone marrow (BM) aspirates. Differential gene expression and Gene Set Variation Analysis of cell signature enrichment scores were assessed by RNAseq using baseline and on-treatment CD138- BM cells. **Results:** In peripheral blood (PB), sBCMA accumulated in pts with progressive disease, though levels remained constant with successive treatment cycles in pts with stable disease. Changes in PB activation markers occurred between 24h and 8d after first infusion, though were not observed in Tira mono treated pts. Transient upregulation of CD69+CD25+ CD4 T cells occurred in a subset of T+D treated pts, while a trend of NK/NKT CD69 upregulation was observed earlier and at a greater magnitude in two of three T+D+A treated pts when compared to T+D. Notably, NK absolute counts decreased by C1D8 in combination arms, consistent with Dara-mediated effects. Frequencies of PB Ki-67+HLA-DR+ CD8 T cells were transiently upregulated by C1D8 in pts receiving T+D+A, and in a subset of T+D treated pts. In the BM, the frequency of PD-1+ CD8 T cells significantly increased between C1D15 and C2D1 in T+D and to a greater extent in T+D+A treated pts. Additional transcriptomic analysis to interrogate modulation of gene expressions and cell signatures over treatment is ongoing, however, initial reports suggest T+D treatment significantly increased NK, CD8 T cell, and macrophage signatures within the BM, but this was not observed with Tira alone. **Conclusions:** The study demonstrated that PD changes in NK and T cell activation in the periphery are among the earliest biomarkers of T+D activity, and that the addition of Atezo may potentiate CD8 T cell responses, suggesting that Tira + Atezo combinations may improve pt outcomes. This is the first clinical study to evaluate biomarkers of novel checkpoint inhibitor combinations in R/R MM, and additional analyses are ongoing to better characterize patient populations that will benefit most from dual checkpoint blockade combinations.

Introduction: Bispecific antibodies targeting B-cell maturation antigen (BCMA) may contribute to increased infection risk among patients with relapsed/refractory multiple myeloma (RRMM) due to on-target, off-tumor toxicity. Teclistamab is the only approved BCMA×CD3 bispecific antibody with a personalized, weight-based, and flexible dosing schedule for the treatment of triple-class exposed RRMM. Based on experience from the phase 1/2 MajesTEC-1 study, we provide preliminary recommendations for managing potential infections during teclistamab treatment. **Methods:** Patients (N=165) received subcutaneous teclistamab 1.5 mg/kg weekly following a step-up dosing schedule. Patients must have had no evidence of serious bacterial, viral, or fungal infections to initiate treatment with teclistamab. Infection monitoring, prophylaxis, and management, including intravenous immunoglobulin G (IVIG), were per institutional guidelines. **Results:** At median follow-up of 21.7 months (range, 0.3–32.7), infections occurred in 129 patients (78.2%) overall (grade 3/4 in 86 patients [52.1%]). Twenty patients (12.1%) died due to infections (17 from COVID-19). Median time to first onset of any grade and grade 3–5 infections was 1.7 and 4.2 months, respectively. Overall, 70.9% of patients had ≥1 immunoglobulin G (IgG) value < 400 mg/dL; 45.5% received IVIG. Grade 3/4 neutropenia occurred in 65.5% of patients at a median of 2.3 months; 53.3% of patients received granulocyte colony-stimulating factor (G-CSF). **Conclusions:** Based on MajesTEC-1, IVIG (administered every 3–6 weeks) is indicated for IgG < 400 mg/dL and for serious or recurrent/chronic infections. Patients should be screened for hepatitis B and C and receive all appropriate vaccinations (including COVID-19) before starting teclistamab. Prophylaxis for Pneumocystis jirovecii pneumonia and herpes viruses is recommended; other prophylactic antimicrobials should be administered per institutional guidelines. G-CSF should be considered for grade ≥3 neutropenia with infection/fever and/or grade 4 neutropenia. Due to the increased infection risk with BCMA-targeting bispecific antibodies, patients should be closely monitored for a range of infection types throughout teclistamab treatment. Data previously presented at the 9th World Congress on Controversies in Multiple Myeloma (COMy) 2023.

Introduction: Bispecific antibodies targeting B-cell maturation antigen (BCMA) may contribute to increased infection risk among patients with relapsed/refractory multiple myeloma (RRMM) due to on-target, off-tumor toxicity. Teclistamab is the only approved BCMA×CD3 bispecific antibody with a personalized, weight-based, and flexible dosing schedule for the treatment of triple-class exposed RRMM. Based on experience from the phase 1/2 MajesTEC-1 study, we provide preliminary recommendations for managing potential infections during teclistamab treatment. **Methods:** Patients (N=165) received subcutaneous teclistamab 1.5 mg/kg weekly following a step-up dosing schedule. Patients must have had no evidence of serious bacterial, viral, or fungal infections to initiate treatment with teclistamab. Infection monitoring, prophylaxis, and management, including intravenous immunoglobulin G (IVIG), were per institutional guidelines. **Results:** At median follow-up of 21.7 months (range, 0.3–32.7), infections occurred in 129 patients (78.2%) overall (grade 3/4 in 86 patients [52.1%]). Twenty patients (12.1%) died due to infections (17 from COVID-19). Median time to first onset of any grade and grade 3–5 infections was 1.7 and 4.2 months, respectively. Overall, 70.9% of patients had ≥1 immunoglobulin G (IgG) value < 400 mg/dL; 45.5% received IVIG. Grade 3/4 neutropenia occurred in 65.5% of patients at a median of 2.3 months; 53.3% of patients received granulocyte colony-stimulating factor (G-CSF). **Conclusions:** Based on MajesTEC-1, IVIG (administered every 3–6 weeks) is indicated for IgG < 400 mg/dL and for serious or recurrent/chronic infections. Patients should be screened for hepatitis B and C and receive all appropriate vaccinations (including COVID-19) before starting teclistamab. Prophylaxis for Pneumocystis jirovecii pneumonia and herpes viruses is recommended; other prophylactic antimicrobials should be administered per institutional guidelines. G-CSF should be considered for grade ≥3 neutropenia with infection/fever and/or grade 4 neutropenia. Due to the increased infection risk with BCMA-targeting bispecific antibodies, patients should be closely monitored for a range of infection types throughout teclistamab treatment. Introduction: BCMA targeted CAR-T therapy is effective at inducing disease remission in heavily pretreated relapsed refractory Multiple Myeloma (MM) patients with a cumulative overall response rate of 85.2%, however, duration has been disappointing. Bone marrow microenvironment (BMM)-derived IL6 is a survival signal for MM cells and is known to promote drug resistance. CAR-T therapy induces an immune response, resulting in increased IL6. With this in mind, we investigated the impact of the BMM and IL6 on CAR-T induced cell death in MM. **Methods:** MM cell lines were exposed to BCMA-CAR-T cells or CD95L for 24 hours and cell death measured via Annexin V staining. CD3, CD38, and mCherry expression were used to distinguish T cells, MM cells, and HS-5 stromal cells respectively. In stromal coculture (SCC) and conditioned media (SCM) assays, MM cells were preincubated for 1 hour before T cell addition. Caspase 8 activity was measured with an IETD-FMK fluorometric assay. **Results:** SCC protected all 3 MM cell lines tested from CAR-T induced cell death while SCM protected 2 of the 3 cell lines. CAR-T CD107a surface expression remained consistent between control and SCC/SCM groups indicating no change in T cell activation. Gene editing to ablate CD95 expression protected 3 of 4 MM cell lines demonstrating its importance in CAR-T induced cell death. Therefore, to determine the mechanism of protection we focused on the effects of SCC, SCM, and IL6 on rCD95L killing. All were sufficient to protect myeloma cells from rCD95L. Loss of mitochondrial-mediated apoptosis through the deletion of BID or BAX/BAK protected 2 of 4 cell lines from rCD95L, indicating that rCD95L induces type 1 (mitochondria-independent) or type 2 (mitochondria-dependent) death in a cell line specific manner. When type 2 cells deficient in mitochondrial apoptosis were cultured in SCM and exposed to rCD95L, there was no enhancement of protection beyond SCM alone. In contrast, when type 1 cells deficient in mitochondrial apoptosis were exposed to rCD95L, the combination of SCM and BAK/BAX DKO protected the type 1 cells beyond SCM alone suggesting an effect upstream of the mitochondria. Consistent with this possibility, SCM inhibits CD95L induced activation of caspase 8 in both type 1 and type 2 cells lines. **Conclusions:** These results demonstrate that the BMM can induce MM cell intrinsic protection against CAR-T therapy in part due to soluble stromal factors. This protection may be due in part to inhibition of the extrinsic apoptotic pathway. Stromal factors including IL6 inhibit rCD95L induced type 1 induced cell death through a reduction in Caspase 8 activity. We hypothesize that reduced caspase 8 activity changes a type 1 cell death signal to a type 2 death signal that can be inhibited by anti-apoptotic BCL2 family.

Introduction: Ide-cel is an FDA-approved treatment for RRMM patients (pts). However, there is limited data on how BT for disease control during its manufacturing process affects clinical outcomes. **Methods:** Eleven US academic centers contributed data to this analysis without involvement from the manufacturer. By 5/1/2022, 235 pts had undergone leukapheresis, with 214 infused with a median follow up of 9 months (mos). BT was given between leukapheresis and CAR-T infusion. **Results:** In this analysis, 79% of pts (n=170) received BT, which included alkylator-based in 35.5%, steroid and or IMiD/Ab combos (IMiD combos) in 14%, PI combinations (PI combos) in 12%, and selinexor in 10%. BT recipients had higher ECOG PS 2-4, R-ISS 2-3, ferritin, and CRP before lymphodepleting (LD) chemo, however, no difference among BT subgroups. No difference in prior lines of therapy or penta-refractory between BT and No BT (NBT) groups or BT subgroups. Median cycle of the BT was 1 (1-7), with overall response rate (ORR) of 12%, with no difference among BT subgroups. Incidence and severity of CRS and ICANs were comparable in BT and NBT. However, pts who received BT had a longer median hospital stay compared to NBT, particularly in the alkylator/selinexor subgroups. There were no significant difference in cytopenias at day 90 post CAR-T between the BT and NBT or BT subgroups. For the 73% (n=157) evaluable for day 90 response, there was no difference in the complete or ORR between the BT and NBT groups (41% vs. 52%; p=0.2 and 84% vs. 87.5%, p=0.8, respectively). Median PFS was worse at 8.1 mos in BT vs 11.5 mos in NBT (p=0.03). Among BT subgroups, PFS was the longest with IMiD combos with median PFS not reached (NR), comparable to NBT, and was significantly longer than all other BT subgroups (p=0.01). The median OS was 13.8 mos with BT and NR in NBT (p=.002). In BT subgroup analysis, alkylators group had a shorter OS, although, this was not significant (p=.06). There was no significant difference in PFS and OS in relationship to response to BT (p=.6 and p=.9, respectively). **Conclusions:** Pts without BT had longer PFS and OS post ide-cel, likely reflective of less aggressive disease. Those who received BT with steroid/IMiD and Ab combos had similar PFS as NBT. However, BT choice is complicated by disease severity and should be evaluated per patient circumstances.

[1]Mayo Clinic

Introduction: The antineoplastic effect of beta blockers (BB) has been widely explored in solid tumors but understudied in hematologic malignancies. We previously reported that BB improved overall survival (OS) and reduced myeloma specific death among patients receiving various multiple myeloma (MM) therapies, and improved progression free survival (PFS) in patients treated with pomalidomide / dexamethasone. No studies have done to explore the antitumor effect in lymphoma. This retrospective study evaluated the outcomes of patients taking BB who received CAR-T therapy for MM and non-Hodgkin lymphoma (NHL). **Methods:** We identified 217 patients received CAR-T at Mayo Clinic between January 2018 and September 2022 for MM (n=63) and NHL (n=154). BB usage was extracted from patient records. Peri-CART BB intake was defined as ≥ 3 months BB intake prior to and post CAR-T to evaluate CRS and neurotoxicity. Post-CART BB usage groups, defined as ≥ 3 months of BB intake following CAR-T, were compared to evaluate PFS and OS from CAR-T. OS from diagnosis was analyzed between patients with BB intake of ≥ 3 months at any time after diagnosis and no-BB usage group. Kaplan-Meier method was used to estimate the PFS and OS. **Results:** During the peri-CAR-T period, there were 46 BB users and 171 non-BB users (median age of 67 versus 61 years, p=0.0005). Both groups had male predominance (70% in BB and 58% in no-BB patients). The time from diagnosis to CAR-T was not significantly different between the BB group and the non-BB group (55 months vs 30 months; p=0.88) nor were there significant differences between two groups in ECOG score, prior-line therapies and, if received, bridging therapy. The patients with peri-CART BB consumption, compared to no-BB group, were less likely to develop CRS (71.7% vs 83.6%, p=.06) and had significantly lower severity of CRS (grade ≥ 2: 23.9% vs 43.9%; p=0.01) but comparable ICANS rates. The median follow-up from CAR-T and from diagnosis for surviving patients was 13.2 months and 5.1 years, respectively. The 47 (15 MM, 32 NHL) patients who took BB post-CART, compared to 170 (48 MM, 122 NHL) patients with no post-CART BB intake, had superior PFS (11.1 vs 6.3 months in all patients; 12.2 vs 8.3 months in MM; 7.7 vs 4.7 months in NHL) and superior 1-year OS from CAR-T (81% vs 67% in all patients; 93% vs 79% in MM; 75% vs 62% in NHL). The 60 (16 MM, 44 NHL) patients who took BB at any time after diagnosis had higher 10-year OS from diagnosis than no-BB intake group (64% vs 45%, p=.0105 in all patients; 74% vs 50% in MM, p NS; 57% vs 42% in NHL, p=.007). Comparison of PFS and OS from CAR-T as well as OS from diagnosis in MM did not reach statistical significance due to small sample size and shorter follow up. **Conclusions:** BB intake among patients receiving CAR-T therapy showed reduced risks for CRS and was associated with more favorable survival outcomes. The result warrants further investigation for anti-cancer effect of BB in CAR-T and other immunotherapies.

Introduction: Autologous stem cell transplant (ASCT) improves MRD negativity and prolongs progression free survival in newly diagnosed multiple myeloma (MM) patients. MM NK cells are dysfunctional, negatively impacting outcomes. BHV-1100, an Antibody Recruiting Molecule (ARM), binds to CD38 target cell antigen and recruits NK cells for ADCC. Allogeneic, cytokine induced memory-like (CIML) NK cells effectively treat myeloid disorders. It is not known if autologous CIML NK cells can be obtained and, when coated with BHV-1100, would improve ASCT outcomes in MM. **Methods:** We designed a first-in-human study of autologous CIML NK cells coated ex-vivo with BHV-1100 for MRD+, newly diagnosed MM patients undergoing ASCT. Cells were manufactured in house from non-mobilized lymphapheresis. CIML NK cells were obtained via overnight incubation of enriched NK cells with IL-12 (10ng/ml), IL-15 (100ng/ml), and IL-18 (50ng/ml) and subsequently coated with BHV-1100. The product was infused fresh on D0 after standard melphalan 200 mg/m^2 myeloablative conditioning and followed by stem cells infusion. Low dose IL2 (1 mIU/m^2) was administered SQ starting on D+1, QOD for 7 doses. **Results:** This is an ongoing trial (NCT04634435) with a median follow-up of 191 days. We are herein reporting data on in vivo expansion and functional characterization of ARMored CIML NK for the first 4 patients. CIML NK cells were manufactured with a 100% success rate and infused at a target dose of 5-10x10^6 cells. Patients received between 3.9-6.0x10^6/Kg stem cells. Engraftment based on recovery of neutrophil count occurred on D+12-D+14. There was a 3.5-fold expansion of NK cells in the peripheral blood from D+7 (from 11.1% to 41%) to D+28 that persisted until D+60 (25% total PBMC). Most expanded NK cells were CD56dim, CD16high, KIR high and CD57high. CD57 and KIR expression increased over time from D+7 to D+60, whereas NKG2A expression

Engraftment based on recovery of neutrophil count occurred on D+12-D+14. There was a 3.5-fold expansion of NK cells in the peripheral blood from D+7 (from 11.1% to 41%) to D+28 that persisted until D+60 (25% total PBMC). Most expanded NK cells were CD56dim, CD16high, KIR high and CD57high. CD57 and KIR expression increased over time from D+7 to D+60, whereas NKG2A expression

decreased, indicating expansion of mature, activated and cytotoxic NK cells. Regulatory T cells increased by D+7 (3% vs 15% total PBMC) and returned to baseline after D+14. The functional capacity of the infused product was tested in vitro against MOLP8 MM cell line. The BHV-1100 ARMored cells had a higher killing capacity compared to untreated CIML NK cells and were stable for up to 24 hours (92.6% target cell death vs 91.1% at 0H, 90.8% vs 81% at 4H and 75.3 vs 73.8% at 24H, E:T ratio 2:1). ARMored cells also showed increased IFNγ (53% vs 37.5%) and CD107a (26% vs 14.9%) production compared to untreated CIML NK cells. **Conclusions:** Autologous, BHV-1100 ARMored CIML NK cells have enhanced anti-MM activity in vitro and expand and persist in vivo with peak at D+28 after infusion. This represents an innovative approach to boost autologous cancer immunosurveillance in the context of ASCT. Aside from anticipated infusion reactions, no severe/unexpected adverse events were noted; longer follow up is required to assess safety and efficacy.

Association of baseline soluble BCMA with measures of disease burden and response to linvoseltamab: a comprehensive analysis in patients with relapsed/refractory multiple myeloma (RRMM)

Introduction: B-cell maturation antigen (BCMA) is a receptor expressed in normal and malignant plasma cells, which is cleaved to release the ectodomain, known as soluble BCMA (sBCMA). sBCMA concentrations range from normal to very high in patients with MM, and high concentrations reduce the ability of BCMA-directed therapies to induce cytotoxicity of MM cells in vitro (Frerichs, et al. Clin Cancer Res. 2020). Based on these data and correlations of sBCMA to plasma cell levels and M protein in patients with MM (Ghermezi, et al. Haematologica. 2017), it was hypothesized that high circulating sBCMA may reflect high disease burden and correlate with lower response to plasma cell-targeting T-cell engagers (Girgis, et al. Blood Adv. 2023). Since MM cells vary in their secretion of disease proteins, we evaluated the relationship between sBCMA and M protein, involved free light chains (FLCs), IgA, and bone marrow (BM) plasma cells. We also assessed response to linvoseltamab, a BCMA×CD3 bispecific antibody, in patients with RRMM with high vs low baseline sBCMA. **Methods:** A sandwich ELISA was established for human sBCMA, with a sensitivity of 1.56 ng/mL in neat serum. Baseline serum samples were collected from 2 clinical trials in RRMM (NCT03761108 and NCT04083534; N=302 for sBCMA analysis). Baseline levels of M protein, FLC kappa, FLC lambda, and IgA were quantified using standard techniques. Baseline BM plasma cells were quantified using EuroFlow at a central laboratory. Spearman correlations were performed to assess the relationships between sBCMA and disease parameters. To assess correlation between baseline sBCMA and objective response rate (ORR) in patients treated with the recommended Ph 2 dose (RP2D) of linvoseltamab (N=117), an analysis by baseline sBCMA concentrations according to tertiles was performed. **Results:** Baseline sBCMA ranged from 17.1–10,200 ng/mL. Median concentrations in our studies were higher than in other reports in RRMM (Girgis, et al. Blood Adv. 2023). Baseline sBCMA was correlated to serum M protein (rho=0.42, P=3.1 e-08), and modestly correlated to involved FLC (rho=0.67, P=6.2 e-08). Correlations to IgA in patients with IgA myeloma at baseline were also modest (rho=0.52, P=1.1 e-05). Correlation of sBCMA to pretreatment BM aspirate plasma cells was weak (rho=0.26, P=00062). Overall ORR was 71% in the cohort of patients treated at the RP2D of linvoseltamab 200 mg. The ORRs according to tertiles of baseline sBCMA were 91.7% (≤210 ng/mL), 70.6% (>210–≤607 ng/mL), and 55.9% (>607–≤4460 ng/mL). **Conclusions:** In contrast to previous data indicating that sBCMA is highly correlated with disease burden, our study demonstrates variable correlations to secretory proteins in patients with RRMM. While prior studies suggested that patients with high baseline sBCMA may have a low response to bispecific therapeutics targeting BCMA and GPRC5D, our study shows that a high ORR can be achieved with linvoseltamab 200 mg in patients with RRMM, including in those with high sBCMA concentrations.

Introduction: Forimtamig is a GPRC5DxCD3 T-cell engaging bispecific antibody that induces T-cell directed Multiple Myeloma

(MM) cell killing and has shown promising clinical activity in a Phase I study in patients (pts) with relapsed refractory MM (NCT04557150; Carlo-Stella et al. ASH 2022). Soluble B-cell maturation antigen (sBCMA) was demonstrated to correlate with tumor burden, is a potential prognostic marker and, having shorter half-life compared to other peripheral MM disease markers, is a promising early response predictor in MM (Nakamura et al. EHA 2022, Girgis et al. Blood Adv. 2023). Here, we investigate sBCMA as a blood-based surrogate marker of clinical response and disease monitoring for forimtamig treatment. **Methods:** Plasma samples were collected in the NCT04557150 dose-escalation study. sBCMA and cytokines were quantified with Protein ELLA System. Peripheral blood immune cells were monitored with flow cytometry and minimal residual disease (MRD) was measured by next generation sequencing. Pts were grouped by age, prior therapy, refractory status, ISS score, cytogenetic risk (high risk: del(17p), t(4;14), t(14;16)) and objective response (responder [≥PR] or non-responder [< PR]). All pts provided informed consent. Updated data will be presented. **Results:** At cut-off (January 25, 2023), 109/120 pts were biomarker evaluable. Baseline sBCMA levels did not significantly differ between pt groups defined by age, refractory status, ISS score, number of prior therapy lines, prior anti-CD38 or anti-BCMA therapy. Pts with high-risk cytogenetics (n=30) tend to have higher baseline levels of sBCMA than standard risk pts (n=16); median: 619.5 ng/mL vs 271.0 ng/mL, p=0.0439. Patients with baseline sBCMA concentrations below median had a higher ORR (above and below median ORR of 55.6% and 80.0%, respectively). A drop in sBCMA levels was detected as early as C1D8 (median=-22.4%) reaching a median of -88.8% by C2D1 in responding pts, whereas sBCMA concentrations increased in non-responding pts (median of 6.7% and 5.1% at C1D8 and C2D1, respectively). Pts with an early drop of sBCMA showed higher likelihood of strong T-cell margination (86% vs. 15%), increase in T-cell proliferation (76% vs. 28%) and modest increase in inflammatory cytokine release compared to those pts without an early drop of sBCMA. ≥50% decrease in sBCMA levels at C2D1 was associated with higher rate of MRD negativity at the same time point: 10-5 MRD neg reported for 13 out of 32 pts (40.6%). All pts not reaching the 50% sBCMA threshold level at C2D1 were MRD positive (n=9). **Conclusions:** sBCMA is a blood-based biomarker that is easily applicable, cost effective, and has potential prognostic value. For the first time, our data indicates a correlation of sBMCA decrease with T-cell activation and MRD negativity. Based on the results of our study, sBCMA may be used as a patient-centric and dynamic surrogate biomarker of response complementary to MRD in the future.

Prognostic impact of corticosteroid and tocilizumab use on the efficacy of chimeric antigen receptor T-cell therapy for relapsed/refractory multiple myeloma

Bruno Costa[1], Jessica Flynn[2], Karthik Nath[3], Noriko Nishimura[3], Sean Devlin[2], Tasmin Farzana[3], David Chung[4], Heather Landau[4], Oscar Lahoud[2], Michael Scordo[2], Gunjan Shah[2], Hani Hassoun[5], Kylee Maclachlan[5], Malin Hultcrantz[5], Neha Korde[5], Alexander Lesokhin[2], Urvi Shah[5], Carlyn Rose Tan[2], Sergio Giralt[2], Saad Usmani[2], Sham Mailankody[5]

[1]Mount Sinai Morningside and West, Icahn School of Medicine at Mount Sinai; [2]Memorial Sloan Kettering Cancer Center, New York City NY, USA; [3]Department of Medicine, Memorial Sloan Kettering Cancer Center; [4]Bone Marrow Transplant and Cellular Therapy, Memorial Sloan Kettering Cancer Center, New York City NY, USA; [5]Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: Chimeric antigen receptor T-cell (CAR-T) therapy targeting B-cell maturation antigen (BCMA) or G protein-coupled receptor, class C, group 5, member D (GPRC5D) has shown unprecedented efficacy in patients (pts) with relapsed/refractory multiple myeloma (RRMM). Immune-related adverse events (irAEs) such as cytokine release syndrome (CRS) and neurotoxicity may occur early in treatment. Whilst immune-suppressive agents such as tocilizumab (TCZ) and corticosteroids (CS) are used to manage irAEs, a potential concern is a negative effect on CAR-T efficacy and survival outcomes. Here, we evaluated the prognostic impact of TCZ and CS use within 30 days of CAR-T infusion. **Methods:** This was a single-center, retrospective cohort study involving RRMM pts aged ≥18 years and treated with commercial/investigational anti-BCMA or anti-GPRC5D CAR-T therapy from April 2017 to September 2022. Fisher's exact test was used to determine whether CS use influenced the overall response rate (ORR; ≥PR as per IMWG Criteria). We also performed a 30-day landmark analysis using multivariable Cox proportional hazards models to evaluate the impact of TCZ administration and CS administration/dosing on progression-free survival (PFS) and overall survival (OS). **Results:** Among the 102 pts included (46% female), the median age was 62 years (range, 37-79) and median number of prior lines of therapy was 6 (range, 2-20). Triple-class refractoriness (TCR), extramedullary disease (EMD), and high-risk cytogenetics were present in 83%, 49%, and 70% of pts, respectively. Anti-BCMA CAR-T was used in 93 pts (91%), and anti-GPRC5D CAR-T in 9 pts (9%). After CAR-T infusion, 77% of pts developed CRS (35% grade 1; 34% grade 2; 8% grade 3) and 14% developed neurotoxicity (8% grade 1; 4% grade 2; 2% grade 3). A total of 42 pts (41%) and 29 pts (28%) received TCZ and CS within 30 days post-infusion, respectively. No significant difference in ORR was observed between pts who received CS and those that did not (66% vs 83%; P=0.089). Following a 30-day landmark analysis, both PFS and OS were significantly inferior in pts with EMD with hazard ratio (HR) of 1.86 (95% confidence interval [CI], 1.05-3.29; P=0.034) and 3.88 (95% CI, 1.71-8.76; P20 mg vs ≤20 mg). Similarly, there was no significant difference in either PFS (HR, 1.06; 95% CI, 0.55-2.04; P=0.87) or OS (HR, 1.03; 95% CI, 0.40-2.68; P=0.95) in pts who received TCZ versus those that did not. **Conclusions:** CS and TCZ treatment for irAEs does not appear to compromise CAR-T efficacy or survival outcomes in RRMM pts. These results support the timely and appropriate use of these drugs for attenuating CAR-T-related toxicities.

(MM) cell killing and has shown promising clinical activity in a Phase I study in patients (pts) with relapsed refractory MM (NCT04557150; Carlo-Stella et al. ASH 2022). Soluble B-cell maturation antigen (sBCMA) was demonstrated to correlate with tumor burden, is a potential prognostic marker and, having shorter half-life compared to other peripheral MM disease markers, is a promising early response predictor in MM (Nakamura et al. Introduction: Chimeric antigen receptor T-cell (CAR-T) therapy targeting B-cell maturation antigen (BCMA) or G protein-coupled receptor, class C, group 5, member D (GPRC5D) has shown unprecedented efficacy in patients (pts) with relapsed/refractory multiple myeloma (RRMM). Immune-related adverse events (irAEs) such as cytokine release syndrome (CRS) and neurotoxicity may occur early in treatment. Whilst immune-suppressive agents such as tocilizumab (TCZ) and corticosteroids (CS) are used to manage irAEs, a potential concern is a negative effect on CAR-T efficacy and survival outcomes. Here, we evaluated the prognostic impact of TCZ and CS use within 30 days of CAR-T infusion. **Methods:** This was a single-center, retrospective cohort study involving RRMM pts aged ≥18 years and treated with commercial/investigational anti-BCMA or anti-GPRC5D CAR-T therapy from April 2017 to September 2022. Fisher's exact test was used to determine whether CS use influenced the overall response rate (ORR; ≥PR as per IMWG Criteria). We also performed a 30-day landmark analysis using multivariable Cox proportional hazards models to evaluate the impact of TCZ administration and CS administration/dosing on progression-free survival (PFS) and overall survival (OS). **Results:** Among the 102 pts included (46% female), the median age was 62 years (range, 37-79) and median number of prior lines of therapy was 6 (range, 2-20). Triple-class refractoriness (TCR), extramedullary disease (EMD), and high-risk cytogenetics were present in 83%, 49%, and 70% of pts, respectively. Anti-BCMA CAR-T was used in 93 pts (91%), and anti-GPRC5D CAR-T in 9 pts (9%). After CAR-T infusion, 77% of pts developed CRS (35% grade 1; 34% grade 2; 8% grade 3) and 14% developed neurotoxicity (8% grade 1; 4% grade 2; 2% grade 3). A total of 42 pts (41%) and 29 pts (28%) received TCZ and CS within 30 days post-infusion, respectively. No significant difference in ORR was observed between pts who received CS and those that did not (66% vs 83%; P=0.089). Following a 30-day landmark analysis, both PFS and OS were significantly inferior in pts with EMD with hazard ratio (HR) of 1.86 (95% confidence interval [CI], 1.05-3.29; P=0.034) and 3.88 (95% CI, 1.71-8.76; P20 mg vs ≤20 mg). Similarly, there was no significant difference in either PFS (HR, 1.06; 95% CI, 0.55-2.04; P=0.87) or OS (HR, 1.03; 95% CI, 0.40-2.68; P=0.95) in pts who received TCZ versus those that did not. **Conclusions:** CS and TCZ treatment for irAEs does not appear to compromise CAR-T efficacy or survival outcomes in RRMM pts. These results support the timely and appropriate use of these drugs for attenuating CAR-T-related toxicities.

Introduction: Ide-cel, a BCMA-directed CAR T cell therapy (Tx), significantly improved median progression-free survival (mPFS; 13.3 vs 4.4 mo; HR 0.49; P< 0.001) and overall response rates (ORR; 71 vs 42%; P< 0.001) vs standard (std) regimens in patients (pts) with TCE RRMM in KarMMa-3 (NCT03651128). Optional bridging Tx (BTx) was allowed for disease control in pts randomized to ide-cel. Outcomes in pts in ide-cel arm who received BTx are reported. **Methods:** Pts in KarMMa-3 randomized to ide-cel could receive ≤1 cycle of BTx, selected by investigator before randomization and dependent on last prior Tx. This post hoc analysis based disease burden (DB) on measurable disease pre-leukapheresis (LK; serum/urine M-protein, M-protein, or difference between involved/uninvolved free light chain). Pts who received BTx were grouped based on DB change from LK to ide-cel (≥25% increase; ≥25% decrease; no change). Efficacy (PFS, ORR, complete response rate [CRR], duration of response [DOR]) and safety of ide-cel were assessed. **Results:** Of 254 pts randomized to ide-cel, 213 received BTx; 200 were evaluable for change in DB before ide-cel (DPd, n=45; DVd, n=20; IRd, n=25; Kd, n=26; EPd, n=59; other, n=25) (increase, n=59 [28%]; decrease, n=32 [15%]; no change, n=109 [51%]). Median number of cycles was 1 for all BTx regimens. A higher percentage of pts with increased disease had baseline high-risk MM characteristics (extramedullary plasmacytoma, increase, 41%; decrease, 16%; no change, 24%; high-risk cytogenetics, increase, 53%; decrease, 25%; no change, 38%; triple-class–refractory disease, increase, 90%; decrease, 63%; no change, 59%). mPFS (95% CI) was numerically longer in pts with decrease vs increase or no change (increase, 6.9 [2.4–11.8]; decrease, 20.7 [11.2–NR]; no change, 15.1 [12.4–17.3] mo). ORR (95% CI) was numerically higher in pts with decrease vs increase or no change (increase, 56% [43–69]; decrease, 97% [91–100]; no change, 80% [72–87]), with deeper (CRR: increase, 32%; decrease, 56%; no change, 39%), more durable (mDOR [95% CI]: increase, 9.3 [7.5–17.3]; decrease, 18.6 [8.6–NR]; no change, 12.9 [10.9–21.4] mo) responses. Any-grade (G; increase, 90%; decrease, 97%; no change, 96%) and G3/4 adverse event (AE; increase, 81%; decrease, 84%; no change, 95%) incidence was similar between groups. G5 AEs occurred in 15% (increase), 6% (decrease) and 13% (no change); serious AEs in 42%, 25%, and 44%, respectively. Any-G cytokine release syndrome occurred in 80% (increase), 94% (decrease), and 84% (no change); G3/4 in 7%, 3%, and 4%, respectively. Any-G investigator-identified neurotoxicity occurred in 24% (increase), 3% (decrease), and 13% (no change); G3/4 in 3%, 0%, and 4%, respectively. **Conclusions:** Ide-cel resulted in longer mPFS and greater response in pts with TCE RRMM who had decrease/no change versus increase in DB with BTx. Regardless of change in DB, ide-cel safety profile was consistent. Effective BTx is an important consideration for ide-cel Tx in TCE RRMM.

Introduction: Data on cellular (CAR) T cell dynamics after treatment and the association with response or the occurrence of cytokine release syndrome (CRS) are limited. We performed a longitudinal flow cytometry study to analyze dynamics of CAR T cells and bystander T cells after infusion and correlated findings with CRS and outcome. **Methods:** We analyzed 29 patients treated with commercial CAR T cell products (Ide-cel/Cilta-cel). Based on their response on day 30 following CAR T cell infusion, patients were separated into two groups (CR:n=14, no CR:n=15). To assess longitudinal cellular dynamics of (CAR) T cells, peripheral blood was collected at day of re-infusion (d 0) as well as days 7, 14, 30

Introduction: Data on cellular (CAR) T cell dynamics after treatment and the association with response or the occurrence of cytokine release syndrome (CRS) are limited. We performed a longitudinal flow cytometry study to analyze dynamics of CAR T cells and bystander T cells after infusion and correlated findings with CRS and outcome. **Methods:** We analyzed 29 patients treated with commercial CAR T cell products (Ide-cel/Cilta-cel). Based on their response on day 30 following CAR T cell infusion, patients were separated into two groups (CR:n=14, no CR:n=15). To assess longitudinal cellular dynamics of (CAR) T cells, peripheral blood was collected at day of re-infusion (d 0) as well as days 7, 14, 30

and 100 after infusion. CAR T cells were detected using a biotin labeled BCMA CAR detection reagent. The T cell compartment was furthermore differentiated by flow cytometry into CD4+/CD8+ CAR T cells and into thymic emigrants, naïve T cells, effector and central memory T cells as well as naïve and memory regulatory T cells. **Results:** We found no correlation between infused number of CAR T cells and in vivo expansion of CAR T cells as well as with response and outcome. Peak CAR T cell expansion was detected after two weeks and was predominantly represented by CD8+ cells. Significantly higher numbers of CAR T cells were detected in the first week and first month following infusion in patients in CR (d7: median 63.4/µl vs 7/µl, p=0.046; d30: median 48/µl vs 3/µl, p=0.031). We also observed significant differences between patients in CR as compared to patients with suboptimal response in the non-CAR T cell compartment. While patients not in CR exhibited significantly higher numbers of naïve CD4+ and CD8+ T cells as well as naïve regulatory T cells during the first months after treatment, patients in CR harbored a significantly higher proportion of CD4+ and CD8+ effector memory T cells one moths after treatment (CD4+:58% vs 33% of all CD4+ T cells,p=0.002; CD8+:59% vs 47%,p=0.018). Overall, 17 patients (59%) developed a CRS (grade 1:n=15,grade 2:n=2). Patients developing a CRS showed significantly higher numbers of CAR T cells in the first week (median 104/µl vs 8/µl, p=0.011) and first month (median 19/µl vs 1/µl, p=0.002) following reinfusion. The expansion of CD8+ effector memory T cells two weeks after infusion was significantly correlated to the occurrence of CRS (CRS: median 191/µl vs no CRS: 46/µl, p=0.006). In patients without CRS, significantly higher numbers of central memory CD4+ (median 35/µl vs 12/µl, p=0.007) and CD8+ T cells (median 10/µl versus 3/µl, p=0.019) as well as naïve CD8+ cells (median 1.3/µl vs 0.1/µl, p=0.021) were observed during the first week. **Conclusions:** Longitudinal analyses of CAR T cells and non-transduced T cells show that their numbers correlate with outcome and toxicity of CAR T cell therapy in patients with multiple myeloma. Our study identified patients at risk for relapse and CRS based on the post-treatment cellular dynamics.

Tumor-intrinsic features associated with progression-free survival (PFS) in patients (pts) with relapsed and refractory multiple myeloma (RRMM) treated with idecabtagene vicleucel (ide-cel)

Nicholas Stong[1], Ethan Thompson[1], Amy Xu[1], Julie Rytlewski[1], Arnaud Amzallag[1], Timothy Campbell[1], Sundar Jagannath[2], Nikhil Munshi[3], Julia Piasecki[1], Debashree Basudhar[1], Maria Ortiz-Estévez[1], Shari Kaiser[1], Nathan Martin[1], Erin Flynt[4]

[1]Bristol Myers Squibb, Princeton, NJ, USA; [2]Mount Sinai Medical Center, New York, NY, USA; [3]Dana-Farber Cancer Institute, Boston, MA, USA, Veterans Affairs Boston Healthcare System/Harvard Medical School; [4]Bristol Myers Squibb, Summit, NJ, USA

Introduction: Ide-cel, a B-cell maturation antigen chimeric antigen receptor T cell therapy, has demonstrated frequent, deep, durable responses in pts with RRMM in the KarMMa (NCT03361748), KarMMa-2 (NCT03601078), and KarMMa-3 (NCT03651128) trials. A previous analysis of KarMMa showed comparable efficacy of ide-cel across molecular high-risk/resistance (HR/R) features such as biallelic p53 inactivation, 1q amplification, t(4;14), and CRBN dysregulation, and identified a baseline gene expression pattern (PC4) associated with PFS (Martin N, et al. Hemasphere 2022;6:(S6):1452). We aimed to identify additional genomic features associated with ide-cel efficacy in KarMMa and KarMMa-2 and evaluate samples from pts in KarMMa-3 as an independent validation cohort. **Methods:** Transcriptional and genomic profiles were assessed at baseline in CD138+ cells from bone marrow from pts in KarMMa, KarMMa-2 cohort 1, and KarMMa-3. Gene copy number aberrations were evaluated for associations with response. Analyses were post hoc and exploratory, and a P value, or false discovery rate (FDR), of < 0.05 was used to identify associations of interest. **Results:** In evaluable pts in KarMMa (n=70), single copy number loss was observed at 2 loci that associated with PFS, a broad region across 14q (n=16) and deletion at 1p31.2 (n=6). These were generally independent and together represented 30% (21/70) of pts. Both were associated with shorter median PFS (mPFS) in KarMMa (cohort mPFS, 8.8 mo, n=128; Munshi et al. N Engl J Med 2021;384:705–716) after FDR correction (del 14q, mPFS, 4.0 mo; del 1p31.2, mPFS, 2.3 mo). No pt with 1p loss had a best overall response (BOR) better than partial response. Pts with loss vs non-loss of 14q had similar BOR distribution, but poorer mPFS within each BOR (10.4 vs 29.7 mo for loss vs non-loss in pts with complete response/stringent complete response). Due to small sample size in KarMMa-2 cohort 1 (n=18), these data were aggregated with those from KarMMa. When combined, previously described associations with HR/R features were maintained except for biallelic p53 inactivation, which showed a stronger association with shorter PFS in the aggregate dataset (n=83, P=0.04) than in KarMMa (n=65, P=0.09). KarMMa-3 (n=210) analysis is ongoing and will be used as a validation cohort for these findings. Consistent trends for the association of the PC4 gene signature with PFS were observed in KarMMa-2 but were not statistically significant and limited by sample size. **Conclusions:** Two novel genomic HR/R features associated with PFS were identified using samples from KarMMa; validation is ongoing using samples from KarMMa-3. The PC4 gene signature was consistent in 2 RRMM cohorts. A modest association between biallelic p53 disruption and PFS emerged with increased sample size and will be studied in KarMMa-3.

We aimed to identify additional genomic features associated with ide-cel efficacy in KarMMa and KarMMa-2 and evaluate samples from pts in KarMMa-3 as an independent validation cohort. **Methods:** Transcriptional and genomic profiles were assessed at baseline in CD138+ cells from bone marrow from pts in KarMMa, KarMMa-2 cohort 1, and KarMMa-3. Gene copy number aberrations were evaluated for associations with response. Analyses were post hoc and exploratory, and a P value, or false discovery rate (FDR), of < 0.05 was used to identify associations of interest. **Results:** In evaluable pts in KarMMa (n=70), single copy number loss was observed at 2 loci that associated with PFS, a broad region across 14q (n=16) and deletion at 1p31.2 (n=6). These were generally independent and together represented 30% (21/70) of pts. Both were associated with shorter median PFS (mPFS) in KarMMa (cohort mPFS, 8.8 mo, n=128; Munshi et al. N Engl J Med 2021;384:705–716) after FDR correction (del 14q, mPFS, 4.0 mo; del 1p31.2, mPFS, 2.3 mo). No pt with 1p loss had a best overall response (BOR) better than partial response. Pts with loss vs non-loss of 14q had similar BOR distribution, but poorer mPFS within each BOR (10.4 vs 29.7 mo for loss vs non-loss in pts with complete response/stringent complete response). Due to small sample size in KarMMa-2 cohort 1 (n=18), these data were aggregated with those from KarMMa. When combined, previously described associations with HR/R features were maintained except for biallelic p53 inactivation, which showed a stronger association with shorter PFS in the aggregate dataset (n=83, P=0.04) than in KarMMa (n=65, P=0.09). KarMMa-3 (n=210) analysis is ongoing and will be used as a validation cohort for these findings. Consistent trends for the association of the PC4 gene signature with PFS were observed in KarMMa-2 but were not statistically significant and limited by sample size. **Conclusions:** Two novel genomic HR/R features associated with PFS were identified using samples from KarMMa; validation is ongoing using samples from KarMMa-3. The PC4 gene signature was consistent in 2 RRMM cohorts. A modest association between biallelic p53 disruption and PFS emerged with increased sample size and will be studied in KarMMa-3.

Hematopoietic reconstitution and infections after anti-BCMA CAR T-cell therapy in relapsed/refractory multiple myeloma are associated with pre-CAR-T bridging therapies

Jan Frenking[1,2], Joseph Kauer[1], Marina Hajiyianni[1,3], Elias Mai[1,3], Christian Michel[1], Lilli Sester[1,2], Lukas John[1,2], Carsten Müller-Tidow[1,4],

and 100 after infusion. CAR T cells were detected using a biotin labeled BCMA CAR detection reagent. The T cell compartment was furthermore differentiated by flow cytometry into CD4+/CD8+ CAR T cells and into thymic emigrants, naïve T cells, effector and central memory T cells as well as naïve and memory regulatory T cells. **Results:** We found no correlation between infused number of CAR T cells and in vivo expansion of CAR T cells as well as with response and outcome. Peak CAR T cell expansion was detected after two weeks and was predominantly represented by CD8+ cells. Significantly higher numbers of CAR T cells were detected in the first week and first month following infusion in patients in CR (d7: median 63.4/µl vs 7/µl, p=0.046; d30: median 48/µl vs 3/µl, p=0.031). We also observed significant differences between patients in CR as compared to patients with suboptimal response in the non-CAR T cell compartment. While patients not in CR exhibited significantly higher numbers of naïve CD4+ and CD8+ T cells as well as naïve regulatory T cells during the first months after treatment, patients in CR harbored a significantly higher proportion of CD4+ and CD8+ effector memory T cells one moths after treatment (CD4+:58% vs 33% of all CD4+ T cells,p=0.002; CD8+:59% vs 47%,p=0.018). Overall, 17 patients (59%) developed a CRS (grade 1:n=15,grade 2:n=2). Patients developing a CRS showed significantly higher numbers of CAR T cells in the first week (median 104/µl vs 8/µl, p=0.011) and first month (median 19/µl vs 1/µl, p=0.002) following reinfusion. The expansion of CD8+ effector memory T cells two weeks after infusion was significantly correlated to the occurrence of CRS (CRS: median 191/µl vs no CRS: 46/µl, p=0.006). In patients without CRS, significantly higher numbers of central memory CD4+ (median 35/µl vs 12/µl, p=0.007) and CD8+ T cells (median 10/µl versus 3/µl, p=0.019) as well as naïve CD8+ cells (median 1.3/µl vs 0.1/µl, p=0.021) were observed during the first week. **Conclusions:** Longitudinal analyses of CAR T cells and non-transduced T cells show that their numbers correlate with outcome and toxicity of CAR T cell therapy in patients with multiple myeloma. Our study identified patients at risk for relapse and CRS based on the post-treatment cellular dynamics.

Introduction: Ide-cel, a B-cell maturation antigen chimeric antigen receptor T cell therapy, has demonstrated frequent, deep, durable responses in pts with RRMM in the KarMMa (NCT03361748), KarMMa-2 (NCT03601078), and KarMMa-3 (NCT03651128) trials. A previous analysis of KarMMa showed comparable efficacy of ide-cel across molecular high-risk/resistance (HR/R) features such as biallelic p53 inactivation, 1q amplification, t(4;14), and CRBN dysregulation, and identified a baseline gene expression pattern (PC4) associated with PFS (Martin N, et al. Hemasphere 2022;6:(S6):1452). We aimed to identify additional genomic features associated with ide-cel efficacy in KarMMa and KarMMa-2 and evaluate samples from pts in KarMMa-3 as an independent validation cohort. **Methods:** Transcriptional and genomic profiles were assessed at baseline in CD138+ cells from bone marrow from pts in KarMMa, KarMMa-2 cohort 1, and KarMMa-3. Gene copy number aberrations were evaluated for associations with response. Analyses were post hoc and exploratory, and a P value, or false discovery rate (FDR), of < 0.05 was used to identify associations of interest. **Results:** In evaluable pts in KarMMa (n=70), single copy number loss was observed at 2 loci that associated with PFS, a broad region across 14q (n=16) and deletion at 1p31.2 (n=6). These were generally independent and together represented 30% (21/70) of pts. Both were associated with shorter median PFS (mPFS) in KarMMa (cohort mPFS, 8.8 mo, n=128; Munshi et al. N Engl J Med 2021;384:705–716) after FDR correction (del 14q, mPFS, 4.0 mo; del 1p31.2, mPFS, 2.3 mo). No pt with 1p loss had a best overall response (BOR) better than partial response. Pts with loss vs non-loss of 14q had similar BOR distribution, but poorer mPFS within each BOR (10.4 vs 29.7 mo for loss vs non-loss in pts with complete response/stringent complete response). Hematopoietic reconstitution and infections after anti-BCMA CAR T-cell therapy in relapsed/refractory multiple myeloma are associated with pre-CAR-T bridging therapies

Jan Frenking[1,2], Joseph Kauer[1], Marina Hajiyianni[1,3], Elias Mai[1,3], Christian Michel[1], Lilli Sester[1,2], Lukas John[1,2], Carsten Müller-Tidow[1,4],

Hartmut Goldschmidt[5], Niels Weinhold[1,2], Anita Schmitt[1], Michael Schmitt[1], Peter Dreger[1], Sandra Sauer[1], Marc Raab[1]

[1]Department of Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany; [2]Clinical Cooperation Unit Molecular Hematology/Oncology, German Cancer Research Center (DKFZ), Heidelberg, Germany; [3]GMMG Study Group at University Hospital Heidelberg, Heidelberg, Germany; [4]National Center for Tumor Diseases (NCT), Heidelberg, Germany; [5]Internal Medicine V, GMMG Study Group at University Hospital Heidelberg, Heidelberg, Germany

Introduction: The time span from patient selection for CAR T-cells to actual infusion is challenging. Pre-apheresis and bridging therapies need to be carefully balanced between disease control, toxicities and effects on T cell fitness. The post-CAR-T phase is characterized by cytopenias and immune deficiency. Considering the diversity of therapeutic options in relapsed/refractory multiple myeloma (RRMM), we evaluated the effect of pre-CAR-T treatment regimens on reconstitution of bone marrow and immune function. **Methods:** We performed a retrospective analysis of RRMM patients who received anti-BCMA CAR T-cells at our academic center. At data cutoff (May 22, 2023), 32 patients had undergone T cell apheresis and 29 patients had received idecabtagene vicleucel (ide-cel). We determined the last documented stable or progressive disease state leading to a systemic treatment prior to apheresis ('pre-apheresis therapy'). 'Bridging therapy' was defined as any systemic treatment applied between apheresis and start of lymphodepletion. For analysis of the post-CAR-T phase, bridging therapies were divided into regimens with ≥ 2 (n=11), ≥ 1 (n=15), or no classical cytotoxic/chemotherapeutic (CTX) agents (n=10), with last cytotoxic drug administration ≤ 60 d before lymphodepletion and exclusion of patients with progressive disease and bone marrow infiltration > 5% (n=2) at time of reconstitution analysis. 14/32 patients had received cyclophosphamide, etoposide and dexamethasone (CED) as pre-apheresis therapy (n=4), bridging therapy (n=4) or both (n=6). Other bridging regimens with ≥ 2 CTX agents were CED-carfilzomib (n=1), BEAM (n=1) and pomalidomide-PACE (n=1). **Results:** CAR T cell therapy with ide-cel resulted in an overall response rate (ORR; ≥ PR) of 72% (n=21), despite a high number of cases with R-ISS ≥ 2 (62%; n=18), high-risk cytogenetics (69%; n=20) and extramedullary disease (48%; n=14). With CED as pre-CAR-T treatment, 11/14 (79%) patients achieved at least stable disease. The ORR was 43% (n=6). Analysis of post-CAR-T hematopoietic reconstitution revealed a delayed recovery in patients after ≥ 2 CTX agents compared to all other bridging therapies. This included lower platelet counts at day 28 (p=0.025), day 35 (p=0.005), day 42 (p=0.009) and day 63 (p=0.015). Leukocyte counts were similarly different from day 28 onward, reaching statistical significance at day 35 (p=0.031), day 42 (p=0.030), day 63 (p=0.015) and day 90 (p=0.028). Two patients required stem cell support (both ≥ 2 CTX group). Infections between days 30 and 90 were more common among patients with ≥ 1 CTX bridging agent (18% vs. 67%; p=0.021). **Conclusions:** The clinical efficacy achieved with ide-cel at our center was comparable with previously published data. CED is effective as pre-apheresis and bridging therapy for RRMM patients with high disease burden. However, CTX-intense regimens appear to be associated with an increased risk for prolonged cytopenias and infections after CAR T-cell therapy.

Introduction: B- cell maturation antigen (BCMA) directed therapy and particularly bi-specific T cell engagers are a therapeutic option for patients (pts) with RRMM. MajesTEC-1 demonstrated an overall response rate (ORR) at 63%, progression free survival (PFS) of 11.3 months and duration of response (DOR) of 18.4 months. Adverse events were mainly low-grade cytokine release syndrome (CRS) (73%), cytopenias, and infections. TEC was FDA approved in October 2022 for RRMM. **Methods:** We retrospectively evaluated outcomes of 28 pts treated with TEC as SOC at our institution from December 2022 to May 2023. CRS and ICANS were graded per ASTCT consensus, responses per IMWG. This retrospective study was IRB approved. **Results:** All pts would have been ineligible for the MajesTEC-1 trial, due to prior BCMA directed therapy (n=22), cytopenias (n=8), renal impairment (n=5), and performance status (PS) (n=4). At the time of TEC, median age was 66 (range 48-81), and 7 pts (25%) had an ECOG PS ≥2. Thirteen pts (46%) had high risk cytogenetics (defined as del17, t(4;14), t(14;16)), and 15 pts (54%) had gain 1q; 10 (36%) were ultra-high risk (double and triple hit). Median prior lines of therapy (LOT) was 7 (4-15). Twenty-six pts (93%) were triple class refractory, and 12 (43%) were penta refractory. Twenty-two pts (79%) received prior BCMA directed therapy; CAR-T (n=16; 73%), Antibody Drug Conjugate (ADC) (n=2; 9%), or both CAR-T and ADC (n=4; 18%). Responses to prior BCMA directed therapies were as follows: 4 progression of disease (PD), 1 stable disease (SD), 1 minimal response (MR), 2 partial response (PR), 4 very good partial response (VGPR), 8 complete response (CR). Twelve (54%) pts received TEC right after progression from prior BCMA directed therapies. Twelve of thirteen pts (all receiving prior BCMA-directed therapy) tested for BCMA expression were positive by IHC, with 7 expressors responding. Twenty-five pts were evaluable for response at day 30. ORR was 52%, with 24% ≥VGPR and 12% ≥CR. ORR in pts with prior BCMA directed therapy was 44%, with 24% ≥VGPR and 12% ≥CR. Grade 1 CRS was seen in 14 (50%) pts, grade 2 in 3 (11%) pts, and grade 3 in 2 (7%) pts. 6 pts received Tocilizumab for CRS; 2 for grade 1 CRS, 2 for grade 2, and 2 for grade 3. One pt received steroids for grade 3 CRS. Grade 3 ICANS was seen in 1 pt (4%), requiring steroids. Infections were seen in 12 (43%)

Median prior lines of therapy (LOT) was 7 (4-15). Twenty-six pts (93%) were triple class refractory, and 12 (43%) were penta refractory. Twenty-two pts (79%) received prior BCMA directed therapy; CAR-T (n=16; 73%), Antibody Drug Conjugate (ADC) (n=2; 9%), or both CAR-T and ADC (n=4; 18%). Responses to prior BCMA directed therapies were as follows: 4 progression of disease (PD), 1 stable disease (SD), 1 minimal response (MR), 2 partial response (PR), 4 very good partial response (VGPR), 8 complete response (CR). Twelve (54%) pts received TEC right after progression from prior BCMA directed therapies. Twelve of thirteen pts (all receiving prior BCMA-directed therapy) tested for BCMA expression were positive by IHC, with 7 expressors responding. Twenty-five pts were evaluable for response at day 30. ORR was 52%, with 24% ≥VGPR and 12% ≥CR. ORR in pts with prior BCMA directed therapy was 44%, with 24% ≥VGPR and 12% ≥CR. Grade 1 CRS was seen in 14 (50%) pts, grade 2 in 3 (11%) pts, and grade 3 in 2 (7%) pts. 6 pts received Tocilizumab for CRS; 2 for grade 1 CRS, 2 for grade 2, and 2 for grade 3. One pt received steroids for grade 3 CRS. Grade 3 ICANS was seen in 1 pt (4%), requiring steroids. Infections were seen in 12 (43%)

pts, including viral, bacterial, and fungal. Five (18%) infections were deemed severe and required hospitalization. Prior to TEC, 14 (50%) pts had hypogammaglobulinemia (IgG< 400). After TEC, 8 pts (29%) developed new hypogammaglobulinemia. Eleven (39%) pts had treatment delays, mainly due to CRS and infections. Four pts died; 1 due to infection, and 3 due to progression of disease. **Conclusions:** Pts treated with SOC TEC had a favorable ORR (52%) despite no pts meeting MajesTEC-1 trial eligibility criteria. No new safety signals were identified. Results will be updated with continued follow up.

Patterns of cytokine release syndrome with teclistamab in relapsed/refractory multiple myeloma with or without prior T-cell redirection therapy

Issam Hamadeh[1], Tala Shekarkhand[1], Colin Rueda[1], Ross Firestone[1], Alice Wang[1], Neha Korde[1], Malin Hultcrantz[1], Alexander Lesokhin[1], Sham Mailankody[1], Hani Hassoun[1], Urvi Shah[1], Kylee Maclachlan[1], Dhwani Patel[1], Gunjan Shah[1], Michael Scordo[1], Oscar Lahoud[1], David Chung[1], Heather Landau[1], Sergio Giralt[1], Saad Usmani[1], Carlyn Rose Tan[1]

[1]Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: Teclistamab (Tec) is a first-in-class BCMA X CD3 bispecific T-cell engager antibody approved for treating relapsed/refractory multiple myeloma (RRMM) after at least 4 lines of therapy (LOT). In the landmark MajesTEC-1 study, cytokine release syndrome (CRS) rate with Tec was 72% (Usmani S, et al. Lancet 2021, Moreau P, et al. N Engl J Med 2022), but patients who previously received T-cell redirection therapies were excluded (TCRT: CAR T-cells and/or other bispecific antibodies). Given this knowledge gap, we examined whether prior TCRT exposure impacts CRS rates with Tec in a real-world setting. **Methods:** Our institutional plasma cell disorders database was queried to identify RRMM patients who received commercial Tec from November 2022 to May 2023. Patients who completed the step-up dosing phase (first step-up, second step-up and first full doses) were divided into two cohorts based on TCRT exposure before Tec (prior TCRT exposure: cohort 1 and no prior TCRT exposure: cohort 2). Data collection included patient demographics, disease characteristics, prior LOT, and rates/grades of CRS and ICANS. The Chi-square/Fisher exact test was used to compare differences in CRS rates between the two cohorts. Univariate and multivariate logistic regression analyses were performed to assess impact of prior TCRT exposure on CRS rates with Tec. Statistical analysis was performed using SPSS software (version 29). **Results:** 41 patients (cohort 1: 21 and cohort 2: 20) were included in the final analysis. Baseline characteristics were comparable between the two cohorts except for previous LOT: 8 (range: 4-13) in cohort 1 and 6 (range: 3-15) in cohort 2 (p=0.02). High-risk cytogenetic abnormalities [t (4;14), t (14;16), t (14;20), TP53 mutations, del 17p and 1q amplification) were present in 71% (n=15) and 40% (n=8) of patients in cohorts 1 and 2, respectively (p=0.06). Extramedullary disease (EMD) was present in 57% (n=12) of patients in cohort 1 and 50% (n=10) in cohort 2. Elevated LDH (prior to teclistamab) was seen in 33% (n=7) of patients in cohort 1 and 15% (n=3) in cohort 2 (p=0.27). CRS rates were significantly lower in cohort 1 (38.1%, n=8) versus cohort 2 (75%, n=15, p=0.03). Grade 2 CRS occurred in 4.8% (n=1) of patients in cohort 1 and 19% (n=4) of patients in cohort 2 (p=0.09). CRS events occurred following the first step-up dose in 5/21 and 10/20 patients in cohort 1 and 2, respectively. In univariate logistic regression analysis, no prior exposure to TCRT was associated with about a 5-fold increase in the incidence of CRS with Tec (95% CI: 1.3-20.2, p=0.042). After adjusting for age, EMD and elevated LDH levels, the impact of prior exposure to TCRT remained significant with an odds ratio of 4.5 (95% CI: 1.1-20.6, p=0.01). **Conclusions:** In our study cohorts, prior exposure to a TCRT was associated with a significantly lower incidence of CRS during Tec step-up dosing phase. This observation will allow for optimization of CRS prophylactic strategies for RRMM patients.

Teclistamab in relapsed and refractory multiple myeloma: patients characteristics from post marketing acces (acces precoce) in France

Stéphanie Harel[1], Jean-Marc Schiano de Colella[2], Cecile Sonntag[3], Titouan Cazaubiel[4], Laurent Garderet[5], Sylvie Bouillie[6], Matthieu Javelot[7], Sophie Vernet[7], Aurore Perrot[8]

[1]Immuno-Hematology Department, Saint-Louis Hospital AP-HP; [2]Institut Paoli Calmettes, CRCM, AMU; [3]Hematology department, ICANS; [4]CHU de Bordeaux, Bordeaux, France; [5]Service d'Hématologie et thérapie cellulaire, Hôpital Saint-Antoine, AP-HP; [6]Janssen-Cilag France; [7]Medical Affair Janssen-Cilag France; [8]Institut Universitaire du Cancer de Toulouse Oncopole, Toulouse, France

Introduction: Acces précoce (AP) is a French procedure facilitating patient (pt) access to innovation addressing high unmet medical needs. Teclistamab (TEC) is a humanized IgG-4 bispecific antibody that binds to B-cell maturation antigen (BCMA) and CD3 and was approved in Europe in August 2022. AP for TEC monotherapy was granted in September 2022, by French health authorities for the treatment of adult patients (pts) with relapsed and refractory multiple myeloma (RRMM), who have received at least 3 prior therapies, including an immunomodulatory agent, a proteasome inhibitor and an anti-CD38 antibody after all treatment options have been exhausted. Here we describe the patient's characteristics included in AP. **Methods:** Data were collected from 14OCT22 to 20APR23 (data cut off) at 2 timepoints (treatment request and discontinuation). AP eligibility criteria were: RRMM, triple-class exposed, ≥3 prior lines of therapies, and all treatment options exhausted (excluding cellular therapies). The approved dose of TEC 1.5mg/kg by subcutaneous injection weekly, preceded by step-doses of 0.06 and 0.3mg/kg was used. **Results:** At data cutoff, 572 treatment request forms were approved. The median age of pts with an approved treatment request was 71 years, with 31.5% over 75 years old. The Median time since diagnosis was 6.3 years. ECOG

pts, including viral, bacterial, and fungal. Five (18%) infections were deemed severe and required hospitalization. Prior to TEC, 14 (50%) pts had hypogammaglobulinemia (IgG< 400). After TEC, 8 pts (29%) developed new hypogammaglobulinemia. Eleven (39%) pts had treatment delays, mainly due to CRS and infections. Four pts died; 1 due to infection, and 3 due to progression of disease. **Conclusions:** Pts treated with SOC TEC had a favorable ORR (52%) despite no pts meeting MajesTEC-1 trial eligibility criteria. No new safety signals were identified. Results will be updated with continued follow up.

Patterns of cytokine release syndrome with teclistamab in relapsed/refractory multiple myeloma with or without prior T-cell redirection therapy

Issam Hamadeh[1], Tala Shekarkhand[1], Colin Rueda[1], Ross Firestone[1], Alice Wang[1], Neha Korde[1], Malin Hultcrantz[1], Alexander Lesokhin[1], Sham Mailankody[1], Hani Hassoun[1], Urvi Shah[1], Kylee Maclachlan[1], Dhwani Patel[1], Gunjan Shah[1], Michael Scordo[1], Oscar Lahoud[1], David Chung[1], Heather Landau[1], Sergio Giralt[1], Saad Usmani[1], Carlyn Rose Tan[1]

[1]Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: Teclistamab (Tec) is a first-in-class BCMA X CD3 bispecific T-cell engager antibody approved for treating relapsed/refractory multiple myeloma (RRMM) after at least 4 lines of therapy (LOT). In the landmark MajesTEC-1 study, cytokine release syndrome (CRS) rate with Tec was 72% (Usmani S, et al. Lancet 2021, Moreau P, et al. N Engl J Med 2022), but patients who previously received T-cell redirection therapies were excluded (TCRT: CAR T-cells and/or other bispecific antibodies). Given this knowledge gap, we examined whether prior TCRT exposure impacts CRS rates with Tec in a real-world setting. **Methods:** Our institutional plasma cell disorders database was queried to identify RRMM patients who received commercial Tec from November 2022 to May 2023. Patients who completed the step-up dosing phase (first step-up, second step-up and first full doses) were divided into two cohorts based on TCRT exposure before Tec (prior TCRT exposure: cohort 1 and no prior TCRT exposure: cohort 2). Data collection included patient demographics, disease characteristics, prior LOT, and rates/grades of CRS and ICANS. The Chi-square/Fisher exact test was used to compare differences in CRS rates between the two cohorts. Univariate and multivariate logistic regression analyses were performed to assess impact of prior TCRT exposure on CRS rates with Tec. Statistical analysis was performed using SPSS software (version 29). **Results:** 41 patients (cohort 1: 21 and cohort 2: 20) were included in the final analysis. Baseline characteristics were comparable between the two cohorts except for previous LOT: 8 (range: 4-13) in cohort 1 and 6 (range: 3-15) in cohort 2 (p=0.02). High-risk cytogenetic abnormalities [t (4;14), t (14;16), t (14;20), TP53 mutations, del 17p and 1q amplification) were present in 71% (n=15) and 40% (n=8) of patients in cohorts 1 and 2, respectively (p=0.06). Extramedullary disease (EMD) was present in 57% (n=12) of patients in cohort 1 and 50% (n=10) in cohort 2. Elevated LDH (prior to teclistamab) was seen in 33% (n=7) of patients in cohort 1 and 15% (n=3) in cohort 2 (p=0.27). CRS rates were significantly lower in cohort 1 (38.1%, n=8) versus cohort 2 (75%, n=15, p=0.03). Grade 2 CRS occurred in 4.8% (n=1) of patients in cohort 1 and 19% (n=4) of patients in cohort 2 (p=0.09). CRS events occurred following the first step-up dose in 5/21 and 10/20 patients in cohort 1 and 2, respectively. In univariate logistic regression analysis, no prior exposure to TCRT was associated with about a 5-fold increase in the incidence of CRS with Tec (95% CI: 1.3-20.2, p=0.042). After adjusting for age, EMD and elevated LDH levels, the impact of prior exposure to TCRT remained significant with an odds ratio of 4.5 (95% CI: 1.1-20.6, p=0.01). **Conclusions:** In our study cohorts, prior exposure to a TCRT was associated with a significantly lower incidence of CRS during Tec step-up dosing phase. This observation will allow for optimization of CRS prophylactic strategies for RRMM patients.

AP eligibility criteria were: RRMM, triple-class exposed, ≥3 prior lines of therapies, and all treatment options exhausted (excluding cellular therapies). The approved dose of TEC 1.5mg/kg by subcutaneous injection weekly, preceded by step-doses of 0.06 and 0.3mg/kg was used. **Results:** At data cutoff, 572 treatment request forms were approved. The median age of pts with an approved treatment request was 71 years, with 31.5% over 75 years old. The Median time since diagnosis was 6.3 years. ECOG

score ≥ 2 was reported for 18.9% and 33,4 % of pts presented with clinically significant comorbidities including hypertension (25,1%), cardiopathy (18%) and renal insufficiency (17,8%). The cytogenetic risk profile was unknown for 35.1% of pts and 21.7% presented with cytogenetic high-risk features, defined as one or more of del17p, t(4,14) or t(14,16). Extramedullary disease was present in 21.2 % of pts. The median number of previous lines of therapy was 4 [3-11]. The percentages of pts having received 3, 4, 5 and ≥6 prior lines were 31.3%, 25.9%, 18.9% and 24% respectively. Pts were previously exposed to lenalidomide and bortezomib (≥97%), daratumumab and pomalidomide (>87%) and carfilzomib (83.2%). 8.6 % pts had been previously treated with a BCMA-targeted therapy. 69.6% pts had triple-class refractory disease and 32 % penta-drug refractory disease. Pts had been included by 230 physicians from 100 different sites: 28 academic hospitals and 72 non-academic centers. The median follow-up was 2.9 [0;6.2] months. As of data cut-off, 38 treatment discontinuations were reported due to disease progression (78.9% with a fatal outcome for 16/30 patients) or toxicity (10.5%). 4 patients died from a treatment-related adverse event. **Conclusions:** This is the largest population of teclistamab patients characterized outside of the clinical trial setting (572 pts included in 6 months). French AP population was heavily pre-treated with clinically significant comorbidities and was slightly older, more frail than patients in the Majestec-1 study population. Academic and non-academic centers have included patients. Only a limited number of treatment discontinuations reported to date.

A Novel CAR-T cell therapy targeting kappa myeloma antigen for the treatment of multiple myeloma

Jane Oliaro[1], Jessica Li[1], Nicole Haynes[1], Katherine Cummins[1], Halley Hilton[2], Rosanne Dunn[2], Simon Harrison[3]

[1]CoE CIT, Peter MacCallum Cancer Centre; [2]HaemaLogiX Ltd, Woolloomooloo, NSW, Australia; [3]Peter MacCallum Cancer Centre and Royal Melbourne Hospital, Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia

Introduction: Multiple myeloma (MM), the second most common blood cancer, is characterized by the accumulation of malignant plasma cells in the bone marrow. Chimeric Antigen Receptor (CAR)-T cell therapy has recently entered the standard of care for relapsed and refractory MM, following the recent FDA-approval of two CAR-T cell products, ide-cel® and cilta-cel®, which target the B cell maturation antigen (BCMA). However, despite impressive response rates, most patients relapse within 1-3 years, highlighting the need to develop novel CAR targets for this disease indication. **Methods:** Kappa (κ) myeloma antigen (KMA) is a tumour specific membrane associated protein expressed on malignant plasma cells in patients with kappa light-chain restricted (κ-type) MM. KMA is absent on normal plasma cells and haematopoietic stem cells, making it an attractive and alternative target antigen for CAR-T cell therapy for MM. The monoclonal antibody, KappaMab (MDX-1097), binds to a conformational epitope on KMA, and has been assessed in phase I, IIa and IIb clinical trials in relapse refractory myeloma patients. Here, we have engineered a lentiviral vector encoding a second-generation CAR expressing a scFv from MDX-1097, fused to a 4-1BB co-stimulatory domain and CD3 zeta chain, to test in preclinical models of MM. **Results:** We successfully generated human anti-KMA CAR-T cells with high and stable CAR expression and a predominately memory T cell phenotype. The CAR-T cells selectively killed KMA-expressing tumour lines and secreted interferon-gamma upon target recognition. Futhermore, a single dose of anti-KMA CAR-T cells demonstrated potent anti-tumour activity in a xenograft model. All mice treated with a 5e6 CAR-T cell dose were alive at 100 days post-treatment, had persisting circulating CAR-T cells and no evidence of disease. **Conclusions:** Our data demonstrates that anti-KMA CAR-T cell therapy is a novel and potent treatment ready to enter a phase I clinical trial for patients with multiple myeloma.

A Novel CAR-T cell therapy targeting kappa myeloma antigen for the treatment of multiple myeloma

Jane Oliaro[1], Jessica Li[1], Nicole Haynes[1], Katherine Cummins[1], Halley Hilton[2], Rosanne Dunn[2], Simon Harrison[3]

[1]CoE CIT, Peter MacCallum Cancer Centre; [2]HaemaLogiX Ltd, Woolloomooloo, NSW, Australia; [3]Peter MacCallum Cancer Centre and Royal Melbourne Hospital, Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia

Introduction: Multiple myeloma (MM), the second most common blood cancer, is characterized by the accumulation of malignant plasma cells in the bone marrow. Chimeric Antigen Receptor (CAR)-T cell therapy has recently entered the standard of care for relapsed and refractory MM, following the recent FDA-approval of two CAR-T cell products, ide-cel® and cilta-cel®, which target the B cell maturation antigen (BCMA). However, despite impressive response rates, most patients relapse within 1-3 years, highlighting the need to develop novel CAR targets for this disease indication. **Methods:** Kappa (κ) myeloma antigen (KMA) is a tumour specific membrane associated protein expressed on malignant plasma cells in patients with kappa light-chain restricted (κ-type) MM. KMA is absent on normal plasma cells and haematopoietic stem cells, making it an attractive and alternative target antigen for CAR-T cell therapy for MM. The monoclonal antibody, KappaMab (MDX-1097), binds to a conformational epitope on KMA, and has been assessed in phase I, IIa and IIb clinical trials in relapse refractory myeloma patients. Here, we have engineered a lentiviral vector encoding a second-generation CAR expressing a scFv from MDX-1097, fused to a 4-1BB co-stimulatory domain and CD3 zeta chain, to test in preclinical models of MM. **Results:** We successfully generated human anti-KMA CAR-T cells with high and stable CAR expression and a predominately memory T cell phenotype. The CAR-T cells selectively killed KMA-expressing tumour lines and secreted interferon-gamma upon target recognition. Futhermore, a single dose of anti-KMA CAR-T cells demonstrated potent anti-tumour activity in a xenograft model. All mice treated with a 5e6 CAR-T cell dose were alive at 100 days post-treatment, had persisting circulating CAR-T cells and no evidence of disease. **Conclusions:** Our data demonstrates that anti-KMA CAR-T cell therapy is a novel and potent treatment ready to enter a phase I clinical trial for patients with multiple myeloma.

Introduction: BCMA-directed T cell engager therapies (TCE), chimeric antigen receptor (CAR) T cells and bispecific T cell engagers (BiTEs) have shown remarkable efficacy in relapsed/ refractory multiple myeloma (RRMM) leading to the approval of

idecabtagene vicleucel, ciltacabtagene autoleucel and teclistamab by the FDA, EMA and other regulatory agencies. We performed a global survey on accessibility, practice patterns, and toxicity management of commercially available TCE therapies. **Methods:** Clinicians attending the IMS Immune Effector Cell Therapies in Multiple Myeloma Workshop (Boston, USA 2023), in-person or virtually, completed an online survey available for 30 days. **Results:** 87 clinicians from 16 countries (North America 64.4%, Europe 25.3%, Asia 6.9%, Australia 3.4%) completed the survey, most practicing in academic practice (86%), in an urban environment (89%). 77% reported CAR-T cell therapy was approved in their country with 44.8% treating 1-5 patients and 14.9% treating >5 patients per month; 67% reported BiTE therapy was approved in their country with 14.9% treating >5 patients per month. Of evaluable responses (n = 40), 62% administered CAR-T therapy inpatient and 15% administered CAR-T therapy outpatient ≥ 50% of the time. Length of time between decision to treat with CAR-T therapy to infusion was 6-12 weeks for 42% of responders and < 6 weeks for 20%. Most (75%) reported inpatient administration of BiTE therapy step-up dosing; 17.5% reported outpatient step-up dosing administered ≥ 50% of the time. 53% prefer cilta-cel, while 23% reported CAR-T therapy preference depended most on patients' co-morbidities (89%), timing of next available apheresis (67%) and age (56%). Maintenance therapy after CAR-T therapy was reported by 25% and 5% of respondents in 1-10% and 11-50% of their patients, respectively, to "maintain level of response achieved" (50%) or "achieve a deeper level of response" (25%). Tocilizumab was used as cytokine release syndrome (CRS) prophylaxis by one responder (2.5%) due to history of prior CRS. Keppra neurologic prophylaxis was used by 47.5% and 15% of responders for CAR-T and BiTE therapy, respectively. Delayed neurotoxicity with CAR-T was reported in 1-5% of patients by 57.5% of responders and 6-10% by 15%; most common manifestations were other movement/neuromuscular disorder (62%), nerve palsy (55%), and Parkinsonism (45%). Infectious prophylaxis included HSV (92.5%), PJP (90%), bacterial pathogens (55%), fungal pathogens (60%), and IVIG (77.5%). Most respondents (46.3 – 86.5%) reported completing an infectious work-up including CMV, EBV, Hep B/C, and HIV. However, 87.5% have not treated an HIV+ patient with CAR-T therapy due to lack of available data or patient need. **Conclusions:** Trends of TCE use and supportive care in MM vary widely among academic centers across the globe, demonstrating a need for further understanding of disease and toxicity management among the international myeloma community, along with improved access beyond urban centers.

Real-world efficacy of CAR T-cell therapies: a HealthTree cure hub's study of multiple myeloma patients

Jay Hydren[1], Jorge Arturo Hurtado Martinez[1], Nathan Sweeney[1], Patricia Alejandra Flores Pérez[1], Andrea Isabel Robles Espinoza[1], Jennifer Ahlstrom[1]

[1]HealthTree Foundation

Introduction: Chimeric antigen receptor T-cell (CAR-T) therapy is a promising immunotherapy that is used in the treatment of patients with relapsed and refractory multiple myeloma (RRMM). The purpose of this study was to analyze real-world data (RWD) and assess the effectiveness of CAR T-cell therapies in patients with RRMM. **Methods:** We utilized HealthTree Cure Hub for Multiple Myeloma, an online portal for patients with plasma cell dyscrasias to analyze RWD from 78 patients who either participated in CAR T-cell clinical trials or received this treatment as an approved intervention for multiple myeloma between the years 2017 and 2022. We assessed the effectiveness of CAR T-cell therapies (Abecma [ide-cel], Carvykti [cilta-cel], orva-cel, and other) by using Kaplan-Meier probability to examine event-free survival (EFS), progression-free survival (PFS), and overall survival (OS). EFS was determined by the start of a non-maintenance therapy and PFS was determined by using the IMWG progressive disease criteria. **Results:** Our analysis of the 78 patients found an average age of 63 ± 9.5 at the time of this analysis and an average age of 61 ± 9.5 at the point of initiating CAR-T therapy. The patients had been treated with an average of 6.5 ± 3.4 prior lines of therapy. Over half of patients (51%) were male, 76% were white, and 55% were non-Hispanic or Latino/a. Of the total 78 patients, 40 received Abecma (ide-cel) as their CAR T-cell therapy, 10 received Carvykti (cilta-cel), 7 received orva-cel, and 21 received other (an incidence of 3 or fewer). The median EFS was 30 months for Abecma (ide-cel), 30 months for orva-cel, 43 months for other, and undefined for Carvykti (cilta-cel). The median PFS and OS was undefined for all CAR T-cell therapies. Additionally, our analysis of EFS, PFS, and OS found no significant difference between the four CAR T-cell therapies. **Conclusions:** Our evaluation of real-world data suggests CAR T-cell therapy is a promising treatment strategy for RRMM regardless of therapy. The findings underscore the advantages of utilizing RWD through digital platforms such as HealthTree Cure Hub. This methodology offers a powerful tool to continually assess the impact of emerging therapeutics within the multiple myeloma patient population.

Prior BCMA-directed bispecific antibody or CAR T is not associated with increased risk of early infections in patients treated with bispecific antibodies

Lawrence Liu[1], Scott R. Goldsmith[2], Sheryl Leahey[2], Carlos Gomez[1], Shawn Streeter[1], Adam Braun[1], Myo Htut[1], Nitya Nathwani[1], Michael Rosenzweig[1], Firoozeh Sahebi[1], Azra Borogovac[1], Arnab Chowdhury[1], Sanjeet Dadwal[1], Amrita Krishnan[1], Murali Janakiram[1]

[1]City of Hope National Comprehensive Cancer Center, Duarte, CA, USA; [2]City Of Hope National Medical Center, Duarte, CA, USA

Introduction: Bispecific antibodies are associated with a higher risk of infections, 50% in a pooled analysis of 1185 patients. Risk factors for early infections with bispecific antibodies remain undefined though hypogammaglobulinemia and neutropenia are postulated to increase risk. **Methods:** We undertook a retrospective analysis of all patients who received bispecific antibodies at our

center between Jan 2017 to Feb 2023. The receipt of a bispecific antibody (BisAb) regimen was considered as a treatment event (TE), if a patient received two different BisAb's regimens over a 12-month period it would be considered as two TE. Clinical predictors of risk and infection data within the first 90 days was collected for each event. **Results:** Our cohort contains 90 patients with 123 TE where 40, 48 and 35 represent regimens with BCMA, GPRC5D and FcRH5 respectively. Within these 123 TE, 77 infection episodes were recorded between days 1 and 90. No infections were recorded in 68 TE, while 41 had one infection and 14 with >=2 infections (36 total). The most common infections recorded were - 38% had Upper respiratory tract infection, 15% blood stream, 13% pneumonia, 14% GI, and 9% had CMV viremia/infection, 8% Urinary tract infections and 3% skin infections. Recurrent infections >1 was higher with BCMA directed therapies in the first 90 days (8.4 vs 17.5%). We divided the cohorts into no infection, 1 infection episode and greater than 1 infection episode. We observed no differences in baseline characteristics between the 3 cohorts including- HR, EMD, RISS, ECOG status, number of lines of prior therapy. On treatment parameters - ANC, ALC at D1, IgG levels, receipt of IVIG, CRS grade, tocilizumab use and treatment dose steroids were also not different between the 3 groups [0,1 and 2 infections]. Multivariate analysis showed none of the covariates including receipt of BCMA vs non BCMA BisAb, HR MM, IgG at baseline, prior CART, or prior BCMA directed therapy to be significantly associated with an increased risk of infection. **Conclusions:** Our results demonstrate that early infection within 90 days is not associated with specific baseline risk factors. Importantly our analysis shows that patients who received prior immune engagers are not at an increased risk of early infections and that IgG levels, ALC and ANC were also not predictive. Other risk factors including duration of prior immune engagers should be explored to identify risk factors for recurrent infections.

[1]University Hospital Ostrava and University of Ostrava, Ostrava, Czech Republic; [2]Alfred Health-Monash University, Melbourne, VIC, Australia; [3]City of Hope, Duarte, CA, USA; [4]Princess Margaret Cancer Centre and University of Toronto, Toronto, ON, Canada; [5]Peter MacCallum Cancer Centre and Royal Melbourne Hospital, Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia; [6]F. Hoffmann-La Roche Ltd, Basel, Switzerland; [7]Genentech, Inc., South San Francisco, CA, USA; [8]Roche Products Ltd, Welwyn Garden City, United Kingdom; [9]Washington University, St. Louis, MO, USA

Introduction: Cevostamab, a FcRH5xCD3 bispecific antibody that facilitates T-cell directed killing of myeloma cells, has shown encouraging activity as monotherapy in patients (pts) with heavily pre-treated RRMM in a Phase 1 study (GO39775; NCT03275103; Trudel et al. ASH 2021). Combining cevostamab with anti-myeloma agents that augment the activity of T cells may enhance efficacy (Li et al. Mol Cancer Ther 2023). Both daratumumab (dara), an anti-CD38 antibody, and pomalidomide (pom), an immunomodulatory drug (IMiD), exhibit T-cell co-stimulatory effects and are clinically active when administered alone or with dexamethasone (dex) in pts with RRMM (Lonial et al. Lancet 2016; San Miguel et al. Lancet Oncol 2013). CAMMA 1 (GO42552; NCT04910568) is an ongoing Phase 1b study evaluating the safety and activity of cevostamab alone (Arm A) or with pom + dex (Arm B) or dara + dex (Arm C) in pts with RRMM. We present initial data from the Arm B safety run-in, including the first efficacy results for a non-B-cell maturation antigen (BCMA)-targeting bispecific antibody + IMiD combination. **Methods:** Eligible pts must have RRMM and have received ≥2 prior lines of therapy, including ≥1 IMiD and ≥1 proteasome inhibitor. Prior pom exposure is allowed. After a pre-phase with step-up dosing, cevostamab is given intravenously every 2 weeks in Cycles (C) 1–6 (28 days per cycle) and every 4 weeks in C7+. From C1+, pom (4 mg PO) is given on Day (D) 1–21 and dex (20 mg) on D1, 8, 15, and 22. At the investigator's discretion, dex may be eliminated from C5+. Treatment continues until disease progression or unacceptable toxicity. **Results:** At data cut-off (February 20, 2023), 8 pts had been enrolled (median age: 64.5 years). Median prior lines of therapy was 4. All pts were triple-class exposed. Median follow-up was 4.8 months. The objective response rate was 100% (8/8 pts), with one patient (12.5%) in complete response, three pts (37.5%) in very good partial response, and 4 pts (50%) in partial response. At cut-off, all responders (8/8 pts) were in response, with responses deepening over time, and 7/8 pts remained on treatment. Grade (Gr) 3–4 adverse events (AEs) occurred in 7 pts (87.5%) and were most commonly neutropenia (Gr 3: 12.5%; Gr 4: 37.5%). Cytokine release syndrome (CRS) occurred in 7 pts (87.5%), with Gr 3 CRS in 2 pts. Both Gr 3 CRS events occurred during the cevostamab pre-phase prior to the addition of pom and resolved without sequelae. AEs leading to dose modification or interruption occurred in all pts. There were no Gr 5 (fatal) AEs. One patient discontinued study treatment due to a serious AE (Gr 3 drug reaction with eosinophils and systemic symptoms [DRESS]) in the setting of cevostamab, pom, and dapsone exposure. **Conclusions:** Cevostamab plus pom and dex shows promising activity in pts with RRMM and warrants further evaluation to optimize the benefit/risk profile. Biomarker and updated clinical data will be presented.

On treatment parameters - ANC, ALC at D1, IgG levels, receipt of IVIG, CRS grade, tocilizumab use and treatment dose steroids were also not different between the 3 groups [0,1 and 2 infections]. Multivariate analysis showed none of the covariates including receipt of BCMA vs non BCMA BisAb, HR MM, IgG at baseline, prior CART, or prior BCMA directed therapy to be significantly associated with an increased risk of infection. **Conclusions:** Our results demonstrate that early infection within 90 days is not associated with specific baseline risk factors. Importantly our analysis shows that patients who received prior immune engagers are not at an increased risk of early infections and that IgG levels, ALC and ANC were also not predictive. Other risk factors including duration of prior immune engagers should be explored to identify risk factors for recurrent infections.

Hoffmann-La Roche Ltd, Basel, Switzerland; [7]Genentech, Inc., South San Francisco, CA, USA; [8]Roche Products Ltd, Welwyn Garden City, United Kingdom; [9]Washington University, St. Louis, MO, USA

Introduction: Cevostamab, a FcRH5xCD3 bispecific antibody that facilitates T-cell directed killing of myeloma cells, has shown encouraging activity as monotherapy in patients (pts) with heavily pre-treated RRMM in a Phase 1 study (GO39775; NCT03275103; Trudel et al. ASH 2021). Combining cevostamab with anti-myeloma agents that augment the activity of T cells may enhance efficacy (Li et al. Mol Cancer Ther 2023). Both daratumumab (dara), an anti-CD38 antibody, and pomalidomide (pom), an immunomodulatory drug (IMiD), exhibit T-cell co-stimulatory effects and are clinically active when administered alone or with dexamethasone (dex) in pts with RRMM (Lonial et al. Lancet 2016; San Miguel et al. Lancet Oncol 2013). CAMMA 1 (GO42552; NCT04910568) is an ongoing Phase 1b study evaluating the safety and activity of cevostamab alone (Arm A) or with pom + dex (Arm B) or dara + dex (Arm C) in pts with RRMM. We present initial data from the Arm B safety run-in, including the first efficacy results for a non-B-cell maturation antigen (BCMA)-targeting bispecific antibody + IMiD combination. **Methods:** Eligible pts must have RRMM and have received ≥2 prior lines of therapy, including ≥1 IMiD and ≥1 proteasome inhibitor. Prior pom exposure is allowed. After a pre-phase with step-up dosing, cevostamab is given intravenously every 2 weeks in Cycles (C) 1–6 (28 days per cycle) and every 4 weeks in C7+. From C1+, pom (4 mg PO) is given on Day (D) 1–21 and dex (20 mg) on D1, 8, 15, and 22. At the investigator's discretion, dex may be eliminated from C5+. Treatment continues until disease progression or unacceptable toxicity. **Results:** At data cut-off (February 20, 2023), 8 pts had been enrolled (median age: 64.5 years). Median prior lines of therapy was 4. All pts were triple-class exposed. Median follow-up was 4.8 months. The objective response rate was 100% (8/8 pts), with one patient (12.5%) in complete response, three pts (37.5%) in very good partial response, and 4 pts (50%) in partial response. At cut-off, all responders (8/8 pts) were in response, with responses deepening over time, and 7/8 pts remained on treatment. Grade (Gr) 3–4 adverse events (AEs) occurred in 7 pts (87.5%) and were most commonly neutropenia (Gr 3: 12.5%; Gr 4: 37.5%). Cytokine release syndrome (CRS) occurred in 7 pts (87.5%), with Gr 3 CRS in 2 pts. Both Gr 3 CRS events occurred during the cevostamab pre-phase prior to the addition of pom and resolved without sequelae. AEs leading to dose modification or interruption occurred in all pts. There were no Gr 5 (fatal) AEs. One patient discontinued study treatment due to a serious AE (Gr 3 drug reaction with eosinophils and systemic symptoms [DRESS]) in the setting of cevostamab, pom, and dapsone exposure. **Conclusions:** Cevostamab plus pom and dex shows promising activity in pts with RRMM and warrants further evaluation to optimize the benefit/risk profile. Biomarker and updated clinical data will be presented.

center between Jan 2017 to Feb 2023. The receipt of a bispecific antibody (BisAb) regimen was considered as a treatment event (TE), if a patient received two different BisAb's regimens over a 12-month period it would be considered as two TE. Clinical predictors of risk and infection data within the first 90 days was collected for each event. **Results:** Our cohort contains 90 patients with 123 TE where 40, 48 and 35 represent regimens with BCMA, GPRC5D and FcRH5 respectively. Within these 123 TE, 77 infection episodes were recorded between days 1 and 90. No infections were recorded in 68 TE, while 41 had one infection and 14 with >=2 infections (36 total). The most common infections recorded were - 38% had Upper respiratory tract infection, 15% blood stream, 13% pneumonia, 14% GI, and 9% had CMV viremia/infection, 8% Urinary tract infections and 3% skin infections. Recurrent infections >1 was higher with BCMA directed therapies in the first 90 days (8.4 vs 17.5%). We divided the cohorts into no infection, 1 infection episode and greater than 1 infection episode. We observed no differences in baseline characteristics between the 3 cohorts including- HR, EMD, RISS, ECOG status, number of lines of prior therapy. On treatment parameters - ANC, ALC at D1, IgG levels, receipt of IVIG, CRS grade, tocilizumab use and treatment dose steroids were also not different between the 3 groups [0,1 and 2 infections]. Multivariate analysis showed none of the covariates including receipt of BCMA vs non BCMA BisAb, HR MM, IgG at baseline, prior CART, or prior BCMA directed therapy to be significantly associated with an increased risk of infection. **Conclusions:** Our results demonstrate that early infection within 90 days is not associated with specific baseline risk factors. Importantly our analysis shows that patients who received prior immune engagers are not at an increased risk of early infections and that IgG levels, ALC and ANC were also not predictive. Other risk factors including duration of prior immune engagers should be explored to identify risk factors for recurrent infections.

Introduction: We have developed a personalized cancer vaccine in which hybridomas are created between patient-derived multiple myeloma (MM) cells and autologous dendritic cells (DCs) such that a broad array of tumor antigens is presented in the context of DC-mediated co-stimulation. BMT CTN 1401 (NCT02728102) is a first-of-its-kind academically led national randomized trial for a personalized cell therapy. We assessed immunologic and clinical response following DC/MM vaccine combined with lenalidomide maintenance (Len) after autoHCT, as compared to maintenance alone. 203 patients were enrolled from 18 centers. To assess the impact of the DC/MM vaccine on the establishment of an anti-MM immune response, we profiled the peripheral blood (PB) immune landscape at the single-cell level pre-/post-vaccination. **Methods:** We performed single-cell immunoprofiling (gene expression + V(D)J sequencing) on 160 PB mononuclear cell (PBMC) samples from 40 patients (DC/MM vaccine/Len/GM-CSF: N=20; Len/GM-CSF: N=10; Len: N=10) collected at enrollment, after 2, and following 3 vaccines (1-year post-transplant). Samples were processed using the 10x Genomics single cell 5' assay. Assessment of samples from the initial cohort (13 vaccinated patients) captured approximately half a million cells, corresponding to 47 cell populations. **Results:** Vaccination with DC/MM fusions as compared to the maintenance therapy alone was associated with a durable expansion of MM reactive T cells at 1-year post-transplant. Preliminary analysis of the vaccine arm identified key immune subsets and provided a detailed characterization of the T-cell landscape (146,373 cells), including subsets of regulatory, effector, and memory compartments. A progressive rise in the relative abundance of CD4 and CD8 T cells was observed after 3 vaccinations compared to the pre-vaccination period. Immune cell repertoire profiling of full-length paired α/β T-cell receptors demonstrated a higher clonotypic expansion of the CD8 effector memory T cells (TCR clonotype frequency > 20) following 2 and 3 vaccinations as compared to pre-vaccination. CD8 T cells showed greater expansion than all other T-cell populations at each time point. Consistent with these findings, a higher proportion of shared epitope/paratope hotspots among the expanded TCR β clonotypes across the vaccinated patients was observed at 1-year post-transplant as compared to the early post-transplant period. The use of BEAM-T 10x Genomics technology is being employed to identify the antigenic targets of the expanded clonotypes. Transcriptomic analysis of the vaccine and control cohorts is being completed. **Conclusions:** Assessment of PBMC samples from vaccinated patients provided a detailed picture of the immune landscape. The constant T cell expansion in patients following vaccination coupled with the shared paratope/epitope hotspots among patients, indicated the TCR cross-reactivity and suggested for the establishment of an anti-MM immune response.

Introduction: CD19-directed CAR T cell therapy results in durable response in a subset of large B cell lymphoma (LBCL) patients in the absence of persistent circulating CAR T cells. We postulated that durable response to CAR T therapy depends on downstream triggering of native T cell immunity. We performed single-cell immunoprofiling on peripheral blood mononuclear cell (PBMC) and RNAseq on baseline tumor from patients participating in the ZUMA 1 study. **Methods:** Single cell immunoprofiling (5' expression + V(D)J, 10x Genomics) was performed on 92 PBMC samples from ZUMA-1 patients (N=32), collected at leukapheresis, 4 weeks, 6- and 12-months post CAR T. RNAseq was performed on FFPE baseline lymphoma samples (N=17). We defined 3 groups: non-responders, relapsed within 1 year from CAR T infusion, and long-term responders. Approximately half a million cells passed the quality check, capturing 73 cellular populations. **Results:** Patients with durable response exhibited significantly higher proportions of CD8 T cells and an increased CD8/CD4 ratio pre-/post-CAR T, compared to the other cohorts. Long-term responders were characterized by a significantly increased cytotoxic signature, mostly pronounced at 4 weeks and 6 months post-CAR T. A higher abundance of CD4 cytotoxic T cells, highly cytotoxic CD8 T cells, as well as of early effector memory and pro-inflammatory CD8 T cells was observed post-CAR T. In contrast, patients with early relapse showed increased levels of regulatory T cells pre-/post-CAR T. In the long-term responder group compared to the patients with refractory or relapsing disease, pairwise comparisons of the TCR proportions before and after CAR T infusion demonstrated a higher

Introduction: CD19-directed CAR T cell therapy results in durable response in a subset of large B cell lymphoma (LBCL) patients in the absence of persistent circulating CAR T cells. We postulated that durable response to CAR T therapy depends on downstream triggering of native T cell immunity. We performed single-cell immunoprofiling on peripheral blood mononuclear cell (PBMC) and RNAseq on baseline tumor from patients participating in the ZUMA 1 study. **Methods:** Single cell immunoprofiling (5' expression + V(D)J, 10x Genomics) was performed on 92 PBMC samples from ZUMA-1 patients (N=32), collected at leukapheresis, 4 weeks, 6- and 12-months post CAR T. RNAseq was performed on FFPE baseline lymphoma samples (N=17). We defined 3 groups: non-responders, relapsed within 1 year from CAR T infusion, and long-term responders. Approximately half a million cells passed the quality check, capturing 73 cellular populations. **Results:** Patients with durable response exhibited significantly higher proportions of CD8 T cells and an increased CD8/CD4 ratio pre-/post-CAR T, compared to the other cohorts. Long-term responders were characterized by a significantly increased cytotoxic signature, mostly pronounced at 4 weeks and 6 months post-CAR T. A higher abundance of CD4 cytotoxic T cells, highly cytotoxic CD8 T cells, as well as of early effector memory and pro-inflammatory CD8 T cells was observed post-CAR T. In contrast, patients with early relapse showed increased levels of regulatory T cells pre-/post-CAR T. In the long-term responder group compared to the patients with refractory or relapsing disease, pairwise comparisons of the TCR proportions before and after CAR T infusion demonstrated a higher

abundance of expanded clonotypes within the cytotoxic CD8 and CD4 T cell compartment, followed by gradually increased numbers over the course of the study. Similar shared PB T cell clones and tumor antigen sequences derived from the RNAseq samples, as well as the high mutational burden, observed in a subset of responders, suggest a (neo)antigen-specific response driven by common epitopes. Monocyte and NK cells were less prevalent in responders before treatment, guided by differences in phagocytic monocyte and inhibitory NK cell abundance. Ligand-receptor expression patterns revealed strong cell-cell interactions between phagocytic monocytes and T regulatory cells 6 months post-CAR T, suggesting a negative immunoregulatory role of these cells. **Conclusions:** The application of single-cell immunoprofiling on longitudinal samples from ZUMA-1 patients demonstrated distinct cellular and clonal profiles between long-term responders and patients with relapsed or refractory disease. These findings support our hypothesis of an important role of the non-CAR T immunity in maintaining sustained response to CAR T therapy. Our results can be used to better understand CAR T therapeutic efficacy and inform patient stratification and management across hematological malignancies.

Development of trogocytosis resistant CAR-NK for multiple myeloma

Marisa K. Kilgour[1], Shelby Kaczmarek[2], Seung-Hwan Lee[2], Scott McComb[3], Alissa Visram[4], Michele Ardolino[1]

[1]Ottawa Hospital Research Institute; [2]University of Ottawa; [3]National Research Council Canada; [4]The Ottawa Hospital

Introduction: Multiple Myeloma (MM) remains an incurable disease, with a median survival of 8.6 months in patients refractory to conventional therapies. There is a great interest in translating chimeric antigen receptor (CAR) therapies to MM, where new therapeutic options are direly needed. Both CAR-T cells, now widely used, and CAR-NK cells, still at an experimental stage, must face evasion mechanisms that make tumor cells resistant to CAR-mediated killing. One of these mechanisms, trogocytosis, has emerged as a major hurdle in the effectiveness of CAR therapy, but strategies to overcome it are still lacking. During trogocytosis, NK cells capture and express the membrane and associated proteins of MM cells on their cell surface leading to negative consequences such as fratricide and antigen loss on the target cells. **Methods:** We set up an in vitro model to study the extent to which CAR-NK cells perform trogocytosis with MM cells and assessed if the structure of the CAR would change the amount of trogocytosis that occurred. We took advantage of NK92 cells, a human NK cell line widely used in preclinical studies, that we transduced with a BCMA targeted CAR construct. We labelled MM cells (with variable expression of BCMA) with Cell Trace Violet (CTV) and co incubated the labelled cells with CAR NK cells. Following 1 hr co incubation, we assessed transfer of cell dye as well as other specific MM markers, including BCMA, by flow cytometry. We repeated this assay with CAR structures varying in the affinity of the antigen binding domain for BCMA and the hinge length. **Results:** Consistent with our hypothesis, CTV dye was transferred to CAR NK cells incubated with MM cell lines, along with BCMA. In contrast, after co incubation with BCMA deficient cells, CAR NK cells failed to stain for BCMA and had lower CTV. Importantly, pre incubating CAR NK cells with the trogocytosis inhibitor latrunculin abolished BCMA acquisition from MM cells. Surprisingly, changing the affinity of the binding domain for BCMA did not alter trogocytosis, however, we found that hinge length had a positive correlation with trogocytosis. In the future, we will apply these methods to primary NK and MM cells as well as in vivo to assess the efficacy of our CAR constructs. **Conclusions:** Taken together, these experiments show that BCMA targeted CAR expression in NK cells greatly enhances trogocytosis of MM antigens, including BCMA. In addition, we demonstrated that the structure of the CAR influences the amount of trogocytosis that occurs. Further studies are needed to determine how we can generate trogocytosis-resistant CAR-NK to improve therapy for MM.

Introduction: Talquetamab (Tal) is a first-in-class GPRC5D×CD3 bispecific antibody that has shown >71% overall response rates (ORRs) and clinically manageable safety in patients (pts) with relapsed/refractory multiple myeloma (RRMM) in the MonumenTAL-1 study. We present subgroup analysis of the efficacy and safety of Tal in pts with disease and clinical features typically associated with poorer outcomes on established myeloma therapies. **Methods:** MonumenTAL-1 (NCT03399799/NCT04634552) is an open-label, single arm, phase 1/2 trial in pts with RRMM.

abundance of expanded clonotypes within the cytotoxic CD8 and CD4 T cell compartment, followed by gradually increased numbers over the course of the study. Similar shared PB T cell clones and tumor antigen sequences derived from the RNAseq samples, as well as the high mutational burden, observed in a subset of responders, suggest a (neo)antigen-specific response driven by common epitopes. Monocyte and NK cells were less prevalent in responders before treatment, guided by differences in phagocytic monocyte and inhibitory NK cell abundance. Ligand-receptor expression patterns revealed strong cell-cell interactions between phagocytic monocytes and T regulatory cells 6 months post-CAR T, suggesting a negative immunoregulatory role of these cells. **Conclusions:** The application of single-cell immunoprofiling on longitudinal samples from ZUMA-1 patients demonstrated distinct cellular and clonal profiles between long-term responders and patients with relapsed or refractory disease. These findings support our hypothesis of an important role of the non-CAR T immunity in maintaining sustained response to CAR T therapy. Our results can be used to better understand CAR T therapeutic efficacy and inform patient stratification and management across hematological malignancies.

Introduction: Multiple Myeloma (MM) remains an incurable disease, with a median survival of 8.6 months in patients refractory to conventional therapies. There is a great interest in translating chimeric antigen receptor (CAR) therapies to MM, where new therapeutic options are direly needed. Both CAR-T cells, now widely used, and CAR-NK cells, still at an experimental stage, must face evasion mechanisms that make tumor cells resistant to CAR-mediated killing. One of these mechanisms, trogocytosis, has emerged as a major hurdle in the effectiveness of CAR therapy, but strategies to overcome it are still lacking. During trogocytosis, NK cells capture and express the membrane and associated proteins of MM cells on their cell surface leading to negative consequences such as fratricide and antigen loss on the target cells. **Methods:** We set up an in vitro model to study the extent to which CAR-NK cells perform trogocytosis with MM cells and assessed if the structure of the CAR would change the amount of trogocytosis that occurred. We took advantage of NK92 cells, a human NK cell line widely used in preclinical studies, that we transduced with a BCMA targeted CAR construct. We labelled MM cells (with variable expression of BCMA) with Cell Trace Violet (CTV) and co incubated the labelled cells with CAR NK cells. Following 1 hr co incubation, we assessed transfer of cell dye as well as other specific MM markers, including BCMA, by flow cytometry. We repeated this assay with CAR structures varying in the affinity of the antigen binding domain for BCMA and the hinge length. **Results:** Consistent with our hypothesis, CTV dye was transferred to CAR NK cells incubated with MM cell lines, along with BCMA. In contrast, after co incubation with BCMA deficient cells, CAR NK cells failed to stain for BCMA and had lower CTV. Importantly, pre incubating CAR NK cells with the trogocytosis inhibitor latrunculin abolished BCMA acquisition from MM cells. Surprisingly, changing the affinity of the binding domain for BCMA did not alter trogocytosis, however, we found that hinge length had a positive correlation with trogocytosis. In the future, we will apply these methods to primary NK and MM cells as well as in vivo to assess the efficacy of our CAR constructs. **Conclusions:** Taken together, these experiments show that BCMA targeted CAR expression in NK cells greatly enhances trogocytosis of MM antigens, including BCMA. In addition, we demonstrated that the structure of the CAR influences the amount of trogocytosis that occurs. Further studies are needed to determine how we can generate trogocytosis-resistant CAR-NK to improve therapy for MM.

Introduction: Talquetamab (Tal) is a first-in-class GPRC5D×CD3 bispecific antibody that has shown >71% overall response rates (ORRs) and clinically manageable safety in patients (pts) with relapsed/refractory multiple myeloma (RRMM) in the MonumenTAL-1 study. We present subgroup analysis of the efficacy and safety of Tal in pts with disease and clinical features typically associated with poorer outcomes on established myeloma therapies. **Methods:** MonumenTAL-1 (NCT03399799/NCT04634552) is an open-label, single arm, phase 1/2 trial in pts with RRMM.

abundance of expanded clonotypes within the cytotoxic CD8 and CD4 T cell compartment, followed by gradually increased numbers over the course of the study. Similar shared PB T cell clones and tumor antigen sequences derived from the RNAseq samples, as well as the high mutational burden, observed in a subset of responders, suggest a (neo)antigen-specific response driven by common epitopes. Monocyte and NK cells were less prevalent in responders before treatment, guided by differences in phagocytic monocyte and inhibitory NK cell abundance. Ligand-receptor expression patterns revealed strong cell-cell interactions between phagocytic monocytes and T regulatory cells 6 months post-CAR T, suggesting a negative immunoregulatory role of these cells. **Conclusions:** The application of single-cell immunoprofiling on longitudinal samples from ZUMA-1 patients demonstrated distinct cellular and clonal profiles between long-term responders and patients with relapsed or refractory disease. These findings support our hypothesis of an important role of the non-CAR T immunity in maintaining sustained response to CAR T therapy. Our results can be used to better understand CAR T therapeutic efficacy and inform patient stratification and management across hematological malignancies.

Introduction: Talquetamab (Tal) is a first-in-class GPRC5D×CD3 bispecific antibody that has shown >71% overall response rates (ORRs) and clinically manageable safety in patients (pts) with relapsed/refractory multiple myeloma (RRMM) in the MonumenTAL-1 study. We present subgroup analysis of the efficacy and safety of Tal in pts with disease and clinical features typically associated with poorer outcomes on established myeloma therapies. **Methods:** MonumenTAL-1 (NCT03399799/NCT04634552) is an open-label, single arm, phase 1/2 trial in pts with RRMM.

Safety and efficacy of pts treated at the recommended phase 2 doses of subcutaneous Tal at 0.4 mg/kg weekly (QW) and 0.8 mg/kg every other week (Q2W) were previously reported. Pt subgroups assessed were age ≥75 years; high-risk cytogenetics [del(17p), t(4;14), and/or t(14;16)]; ISS stage III; renal impairment (baseline function ≤60 mL/min/1.73m^2); triple-class refractory (to a proteasome inhibitor, immunomodulatory drug, and anti-CD38 antibody); and extramedullary disease (EMD; ≥1, including soft tissue plasmacytomas). **Results:** As of Jan 17, 2023, 143 and 145 pts received Tal 0.4 mg/kg QW and 0.8 mg/kg Q2W, respectively. Of these, respectively, 106 (74.1%) and 100 (69.0%) were triple-class refractory; 21 (14.7%) and 32 (22.1%) were ≥75 years; 41 (28.7%) and 37 (25.5%) had high-risk cytogenetics; 28 (19.6%) and 35 (24.1%) were ISS III; 40 (28.0%) and 45 (31.0%) had renal impairment; and 33 (23.1%) and 37 (25.5%) had EMD. Median follow-up for the subgroups was consistent with their respective dose cohorts in the overall population (QW, 19 mo; Q2W, 13 mo). In the Q2W cohort, efficacy was consistent with the broader population (ORR, 72%; 9-mo DOR, 76%; 12-mo PFS, 54%; 12-mo OS, 77%) in the following subgroups: age ≥75 years (ORR, 75%; 9-mo DOR, 92%; 12-mo PFS, 71%; 12-mo OS, 83%), high-risk cytogenetics (ORR, 76%; 9-mo DOR, 78%; 12-mo PFS, 63%; 12-mo OS, 62%), triple-class refractory (ORR, 69%; 9-mo DOR, 73%; 12-mo PFS, 50%; 12-mo OS, 73%) and renal (ORR, 67%; 9-mo DOR, 64%; 12-mo PFS, 40%; 12-mo OS, 72%). Efficacy was lower in ISS III (ORR, 60%; 9-mo DOR, 61%; 12-mo PFS, 38%; 12-mo OS, 67%) and EMD (ORR, 43%; 9-mo DOR, 56%; 12-mo PFS, 27%; 12-mo OS, 65%) subgroups. Trends were similar in the QW cohort. The safety profile among subgroups in both cohorts was generally consistent with the overall population. Rates of discontinuation due to adverse events were higher than the overall population (QW and Q2W, 5–8%) in age ≥75 years (14.3%) and ISS III (10.7%) subgroups in the QW cohort and ISS III (14.3%) and renal (13.3%) subgroups in the Q2W cohort. **Conclusions:** Most pts with traditional high-risk features experience clinical benefit with Tal monotherapy that is consistent with the overall study population. While responses were less consistent in EMD and ISS III subgroups, Tal still provided responses in over one-third and one-half of these pts, respectively.

Early outcomes and therapy modification strategies in multiple myeloma patients treated with teclistamab, CD3XBCMA BITE: a single center experience

Swarup Kumar[1], Katharine Hooper[1], Jackson Clark[1], Alvaro Alvarez-Soto[1], Allison Rounds[1]

[1]University of Connecticut, UCONN Health

Introduction: Cellular therapies in Multiple Myeloma have gained attention in recent years with the first commercially available Bispecific T-cell Engaging Monoclonal Antibody (BITE), CD3XBCMA teclistamab being approved for use for patients with relapsed disease following four or more lines of prior therapy in 2022. The impact of early treatment frequency modification as well as predictive immune markers of response are incompletely understood in this patient population. We aimed to assess and characterize early responses to teclistamab in our patient population as well as understand genomic profiling related mutations identifiable through commercially available assays in predicting treatment response. **Methods:** Nine patients who were treated at our health center with teclistamab between November 2022 and February 2023 were included in this analysis. Patients' baseline characteristics, markers of disease response including hematologic, bone marrow molecular, evaluable minimal residual disease (MRD) at three months post dose escalation completion were abstracted. ClonoSEQ® and Tempus xT® 648 gene DNA NGS panel were utilized for MRD tracking and genomic profiling respectively. **Results:** The median age of the patient population was 75 years (41-81) and the median number of prior lines being 6(4-9). 3 patients had IMWG defined high risk FISH abnormalities and 2 patients had EMP prior to therapy. Mean Absolute Lymphocyte Count prior to therapy was 1.16 (x10^3/ul). 7 patients had cytokine release syndrome (CRS) event while 1 patient had immune effector cell related neurotoxicity (ICANS) event. None of the CRS or ICANS events were grade 3 or higher. Mean absolute CD4 count and CD8 count prior to therapy was 550/cu mm and 622/cu mm. At the 3-moth evaluation, 3 patients had achieved a CR, with 2 being stringent CR, MRD-. 1 VGPR, 2 PR and 3 PD were also observed. Of the 3 patients with CR, 2 patients were treated with Q2 weekly dosing immediately following the dose escalation cycle due to patient tolerance issues, one of whom had also achieved a stringent CR. Amongst all patients with response at the 3-month bone marrow evaluation, 1 patient had DNA damage related mutation (CHEK2) whilst 2 had residual CHIP mutations (TET2 and DNMT3A) with prior exposure to multi-agent antineoplastic therapy (DNA damage agents). **Conclusions:** In our limited patient dataset, 6 (66.7%) patients had achieved an early best response of PR or higher, consistent with clinical trial data. Despite treatment frequency modification, two patients achieved a CR with one patient achieving a stringent CR at the 3-month evaluation. Further studies are needed to assess response adapted treatment frequency modification as well as study genomic perturbations that can alter the function of immune cells (T cells) and impact response to BITE.

Introduction: Cereblon E3 ligase modulator (CELMoD®) agents, including classic immunomodulatory (IMiD®) agents, have antitumor activity in MM. ALNUC is an IgG TCE that binds BCMA and CD3ε in a 2+1 format. ALNUC mediates myeloma cell killing by recruiting T cells to BCMA-expressing target cells, leading to T cell cytotoxic activity. Combining CELMoD agents with ALNUC may enhance antitumor activity. We evaluated the anti-MM potential of ALNUC + pomalidomide (POM) and novel CELMoD agents mezigdomide (MEZI) and iberdomide (IBER) in preclinical models. **Methods:** To evaluate effects of CELMoD agents on ALNUC-mediated T cell anti-MM activity, healthy donor (HD) T cells and/or BCMA-expressing MM cell lines were pretreated with POM, MEZI, IBER, or DMSO for 16 h (T cells) or 72 h (MM cells) prior to coculture; ALNUC was added for 72 h and T cell activation and MM target cell depletion were measured. To evaluate CELMoD agent effects on artificially exhausted T cells, HD CD3+ T cells were pretreated with anti-CD3/CD28 beads and POM, MEZI, IBER, or DMSO for 7 d prior to coculture with MM cells and ALNUC. To determine if CELMoD treatment could reverse T cell dysfunction, pretreatment PBMCs from pts with MM who had response (n=2) or nonresponse (n=3) to ALNUC in a phase 1 trial (NCT03486067) were cocultured with H929 cells. Cocultures were pretreated with MEZI 1 nM for 24 h prior to adding ALNUC. The effects of concurrent and sequential MEZI and ALNUC were studied in a humanized mouse H929 MM xenograft model. **Results:** In cocultures with HD T cells, pretreatment of MM cells with MEZI, IBER, and POM increased ALNUC-induced tumor-cell killing potency and efficacy across all cell lines vs ALNUC alone. ALNUC antitumor activity against the OPM-2 cell line was also enhanced by pretreating T cells with MEZI and IBER, but not POM. MEZI showed the greatest overall enhancement of ALNUC activity. In artificially exhausted HD T cells, enhanced antitumor activity was observed with MEZI and IBER, but not POM, vs DMSO. In a mouse MM xenograft model, priming or concurrent treatment with MEZI enhanced T cell activation, promoted T cell infiltration of tumor tissue, and increased ALNUC-induced tumor clearance. MEZI pretreatment of MM pt-derived PBMCs increased ALNUC-mediated antitumor activity vs control in samples from both responders and nonresponders. **Conclusions:** Combining ALNUC with novel CELMoD agents enhanced T cell mediated antitumor activity in both in vitro and ex vivo MM models. MEZI showed the greatest ability to enhance TCE-mediated antitumor activity while reversing artificial T cell dysfunction/exhaustion. Priming and concurrent treatment with MEZI enhanced ALNUC-induced T cell infiltration and activation in a MM xenograft model. Enhancement of ALNUC T cell antitumor function by MEZI was confirmed using MM patient-derived PBMCs. These results provide a strong biological rationale for combining MEZI or IBER with ALNUC to enhance responses in pts with MM. Presented at ASH 2022. Paiva B et al. Abstract 3135.

[1]Hadassah Medical center; [2]Tel-Aviv Sourasky (Ichilov) Medical Center; [3]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [4]Bar-Ilan University

Introduction: Anti-B-cell maturation antigen (BCMA) chimeric antigen receptor T-cell (CART) therapy shows remarkable efficacy in patients with relapsed and/or refractory (R/R) multiple myeloma (MM). HBI0101 is a novel second generation optimized anti-BCMA CART, that was developed in an academic setting. The phase Ia study evaluating HBI0101 (NCT04720313) proved manageable safety profile and initial high efficacy (Asherie, Haematologica 2022). Here we present the updated phase 1a results as well as the phase 1b results including 50 patients treated to date. **Methods:** At Hadassah Medical Center we have developed a new anti-BCMA CAR T with 4-1BB co-stimulatory domain (HBI0101) for the treatment of R/R MM. Following phase 1a study, evaluating the first 20 R/R MM patients with three or more prior lines of therapy, including a PI, IMiD and anti CD38 antibody (infusing $150x10^6$ (n=6), $450x10^6$ (n=7) and $800x10^6$ (n=7) CAR T cells), the phase Ib study further evaluated the infusion of $800x10^6$ CAR T cells. **Results:** Fifty R/R MM patients were included in the phase Ia and Ib cohorts. The median number of prior lines was 5 (3-13) and most (92%) were triple refractory to PI, IMiDs and anti-CD38 antibodies. 30% were penta-refractory and 30% were refractory to belantamab mofadotin. Safety was manageable with grade 3-4 hematological toxicities common (anemia - 54%, thrombocytopenia - 60%, neutropenia & lymphopenia- 100%). Cytokine release syndrome (CRS) occurred in 46/50 (92%), but were mostly (41/46) of grade 1-2, and manageable with frequent use of tocilizumab (70%). No immune effector cell associated neurotoxicity syndrome (ICANS) cases were observed, and no irreversible organ toxicities or treatment related deaths occurred. The overall response rate (ORR) of the established $800x10^6$ CAR T cells was 87%. Of 37 patients treated with this dose, 21 (57%) achieved complete response (CR)/ stringent CR, and 27 (73%) achieved minimal residual disease (MRD) negativity at day +30. At data cutoff, with a median follow-up of 6 months (range 1-17.4), the median progression-free survival was 11 months and the median overall survival was not reached. Although the presence of extra-medullary disease and prior anti-BCMA therapy correlated with worse outcome, high response rates were still observed (ORR of 96%/63% for patients without/with extra-medullary disease, respectively, and 93%/73% for patients without/with prior anti-BCMA therapy, respectively). **Conclusions:** Our findings demonstrate the manageable safety and high efficacy profiles of HBI0101, comparable to those reported of commercial anti-BCMA CART products. These favorable data are encouraging

Hotspot mutations in BCMA extracellular domain lead to differential susceptibility to anti-BCMA targeted immunotherapies

[1]University of Calgary; [2]University of Miami; [3]MLL Munich; [4]Myeloma Service, Sylvester Comprehensive Cancer Center, University of Miami; [5]Sylvester Comprehensive Cancer Center; [6]Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany; [7]Harvard Medical School; [8]TGen; [9]City of Hope; [10]University Hospital Würzburg; [11]Arnie Charbonneau Cancer Institute, University of Calgary

Introduction: Mutations in TNFRSF17 extracellular domain were recently reported to mediate escape to anti-BCMA bispecific T cell engagers (TCE). The prevalence of these mutations and how they impact other anti-BCMA therapies remain undefined. Furthermore, it is unclear whether these mutations affect BCMA canonical ligand binding and signaling. We here investigated the impact of hotspot mutations in BCMA extracellular domain on the efficacy of anti-BCMA therapies and the emergence of oncogenic dependencies. **Methods:** In order to define the frequency of TNFRSF17 alterations post anti-BCMA therapies and interrogate their functional significance, we collected CD138+ cells from patients treated with anti-BCMA CAR T/ TCE, and subjected the cells to WGS or single cell CNV analysis. Identified BCMA mutations were cloned and transduced into K562 myelogenous cell line for in vitro functional evaluation. **Results:** Recipients of anti-BCMA therapy (CAR T n=5, TCE n=16, both n=3) were included in this analysis. In patients progressing on anti-BCMA CAR T, only one (20%) had biallelic deletion of TNFRSF17 with no BCMA extracellular domain mutations. In contrast, among patients progressing on anti-BCMA TCE (n=14), mutations in TNFRSF17 were observed in 42.8% including TNFRSF17 biallelic loss (n=1) and extracellular domain mutations (n=5). Monoallelic TNFRSF17 deletion were coupled with p.Arg27Pro in one case, while p.Pro34del, or p.Ser30del were observed in 3 and 2 patients, with one patient harboring both mutations, consistent with convergent evolution. None of these mutations were identified in pre-therapy samples using WGS (100x) and digital PCR (0.1% sensitivity). Lentivirally transduced K562 cells were used to characterize the impact of BCMA mutations on the efficacy of various TCEs and cross resistance to CAR T. Of interest, while these mutations differentially impacted the sensitivities of TCEs based on their geometry and valency, cross resistance was not carried out to CAR T cells. As such, while p.Arg27Po, p.Ser30del, and p.Pro34del abrogated teclistamab mediated T cell killing, T cells transduced with teclistamab based scFv CAR retained cytolytic activity. Therefore, TCE resistance derived from BCMA extracellular domain mutations does not preclude retreatment with another anti-BCMA TCE or CAR T. Functionally, while BCMA extracellular domain mutations abrogated the binding of most anti-BCMA TCEs, they did not impair the binding of Fc-tagged APRIL, p65 nuclear translocation, and ERK phosphorylation. **Conclusions:** Collectively, our studies reveal that convergent evolution of MM clones harboring BCMA extracellular domain mutations selectively evade recognition by anti-BCMA TCEs while retaining the pro-survival signaling of the APRIL-BCMA-NFkB axis. Furthermore, these hotspot mutations do not equally confer resistance to all anti-BCMA TCEs or CAR Ts. Dynamic surveillance and functional evaluation of emerging mutant clones will be required to inform and guide therapy selection and sequence.

Introduction: Chimeric antigen receptor (CAR)-T cells directed against B-cell maturation antigen (BCMA), have yielded impressive results in clinical trials for multiply relapsed/refractory multiple myeloma (MM). However, progression free survival is short, demonstrating a need for improvements to this therapy. **Methods:** To enable novel CAR-T cell designs to address this issue, we developed a single domain antibody (sdAb)-based BCMA CAR construct (sdBCMA.41BB.CD3z) upon which to test our modifications. In vitro characterization of our sdAb-based BCMA-directed CAR T-cells using cells isolated from healthy donors will include cytotoxicity, cytokine release, proliferation, and repetitive stimulation. Following these initial in vitro assays, the novel CAR-T cell constructs will be assessed using xenograft models of human MM. As an example of a modification to BCMA CAR-T cells that would address the immunosuppressive MM tumour microenvironment (TME), a cassette containing a single chain IL-12 (schIL-12) was inserted into our CAR transgene, separated by a 2A skip sequence. To enable the study of the MM TME in response to CAR-T cells, we have also developed a murine version of our CAR-T cell construct and are currently evaluating these CAR-T cells in the transplantable Vk*MYC immunocompetent model of MM. **Results:** Using T-cells isolated from human healthy donors, four different sdAb-based BCMA CAR T-cells derived using BCMA sdAbs with varying affinities were tested in co-culture experiments with target cells. When co-cultured with BCMA-expressing target cells, all four CAR-T cells effectively lysed the targets, released inflammatory cytokines, and proliferated. As these short terms in vitro assays showed minimal

and support decentralization of CART production at an academic setting, ensuring a sufficient CART supply in the light of the increasing local demand.

However, progression free survival is short, demonstrating a need for improvements to this therapy. **Methods:** To enable novel CAR-T cell designs to address this issue, we developed a single domain antibody (sdAb)-based BCMA CAR construct (sdBCMA.41BB.CD3z) upon which to test our modifications. In vitro characterization of our sdAb-based BCMA-directed CAR T-cells using cells isolated from healthy donors will include cytotoxicity, cytokine release, proliferation, and repetitive stimulation. Following these initial in vitro assays, the novel CAR-T cell constructs will be assessed using xenograft models of human MM. As an example of a modification to BCMA CAR-T cells that would address the immunosuppressive MM tumour microenvironment (TME), a cassette containing a single chain IL-12 (schIL-12) was inserted into our CAR transgene, separated by a 2A skip sequence. To enable the study of the MM TME in response to CAR-T cells, we have also developed a murine version of our CAR-T cell construct and are currently evaluating these CAR-T cells in the transplantable Vk*MYC immunocompetent model of MM. **Results:** Using T-cells isolated from human healthy donors, four different sdAb-based BCMA CAR T-cells derived using BCMA sdAbs with varying affinities were tested in co-culture experiments with target cells. When co-cultured with BCMA-expressing target cells, all four CAR-T cells effectively lysed the targets, released inflammatory cytokines, and proliferated. As these short terms in vitro assays showed minimal

differences between constructs, longer-term repetitive stimulation to model chronic antigen exposure, paired with immunophenotyping, is underway to identify differences among the constructs. In an NSG xenograft model using MM1S::eGFP cells, administration of one of our constructs, sdBCMA1.41BB.CD3z, CAR T-cells demonstrated a significant improvement in survival and disease control, when compared to control T-cells. Further in vivo testing of the remaining constructs is planned. Insertion of the schIL-12 cassette into the sdBCMA1.41BB.CD3z construct demonstrated effective secretion of IL-12 as detected by ELISA, demonstrating the feasibility of modifications to our sdAb-BCMA CAR-T cells. We provide preliminary evidence of activity in the Vk*MYC model and further work is ongoing to optimize the Vk*MYC model system for murine CAR-T cell evaluation. **Conclusions:** We have shown that our sdAb-based BCMA CAR T-cells are functional, both using in vitro and in vivo models, and now have an asset for further characterization prior to clinical translation. Additional work is on-going to develop an immunocompetent model of CAR-T cells in MM to understand the interactions between the TME, MM cells, and CAR-T cells in vivo.

Prognostic markers for CAR-T cell therapy in patients with relapsed/refractory multiple myeloma

Yang Liu[1], Zhiling Yan[2], Qingyun Wu[2], Chong Chen[2], Jiang Cao[2], Zhenyu Li[2], Kailin Xu[2]

[1]Department of Hematology, The Affiliated Hospital of Xuzhou Medical University; [2]Blood Diseases Institute, Xuzhou Medical University

Introduction: Chimeric antigen receptor (CAR)-T cell therapy has achieved encouraging response rates in patients with Relapsed/Refractory multiple myeloma (R/R MM). However, factors associated with the efficacy and toxicity of CAR-T therapy have not been fully elucidated. We investigated the impact of baseline inflammatory markers and lymphocyte count on the outcomes of R/R MM patients treated with CAR-T cells. **Methods:** The medical records of 109 R/R MM patients who received CAR-T therapy were collected. Biological markers, including absolute lymphocyte count (ALC), ferritin, c-reactive protein (CRP), and interleukin-6 (IL-6) before CAR-T cell infusion were categorized by quartiles. Spearman correlation analysis tested the correlation between inflammatory markers and CRS. Progression-free survival (PFS) and overall survival time (OS) were calculated using Kaplan-Meier method. Factors associated with PFS and OS were evaluated by Log-rank test and Cox proportional hazard model. **Results:** According to the quartile method, 84 patients had high ALC (≥0.8×10^9/L), 27 had high ferritin (>920ng/mL), 27 had high CRP (>20.3 mg/L), 27 had high IL-6 (>14.1 pg/mL). The complete response rate was significantly higher in the high ALC group than in the low ALC group (64% vs. 36%, P = 0.02). Baseline ferritin levels were negatively associated with tumor burden-adjusted CAR-T expansion. High ferritin (hazard ratio [HR] 3.382, P = 0.0007), high CRP (HR 2.043, P = 0.044), high IL-6 (HR 3.298, P = 0.0013) and low ALC (HR 2.7, P = 0.01) were risk factors for OS. High ferritin (HR 2.61, P = 0.002), high IL-6 (HR 2.03, P = 0.018) and low ALC (HR 2.77, P = 0.002) were risk factors of PFS. According to the HR values, the inflammatory prognosis index (InPI) was constructed, high CRP socred 0.5 point, high ferritin and high IL-6 each scored 1 point. The patients were stratified into 3 risk groups: good (0 - 0.5 point, n=67); intermediate (1 - 1.5 points, n=30); poor (2 - 2.5 points, n=12). Median OS for patients with good, intermediate, and poor InPI was not reached, 24 months, and 4 months, respectively, and median PFS was 19.1 months, 12.3 months, and 2.9 months, respectively. Multivariate analysis showed that low ALC, poor InPI and plasma cell ratio ≥50% were independent risk factors for PFS. Light chain type, low ALC, poor InPI and plasma cell ratio ≥50% were independent risk factors for OS. CRS occurred in 91% of the patients, and 13% were grade 3 - 5. The incidence of severe CRS was significantly higher in patients with high IL-6 than in patients with low IL-6 (26% vs. 9%, P = 0.0405). Baseline ferritin (P = 0.0369) and IL-6 (P = 0.0117) were positively correlated with the grade of CRS. Baseline ferritin, CRP and IL-6 were positively correlated with each peak values within the first month after infusion. **Conclusions:** Pre-infusion ALC and inflammatory markers were potential predictors of durable remission and long-term survival, and high inflammation at baseline might predispose patients to severe CRS.

Introduction: Tec is the only approved BCMA×CD3 bispecific antibody with a personalized, weight-based, and flexible dosing schedule for the treatment of triple-class exposed RRMM. Tal, a bispecific antibody targeting the novel myeloma antigen GPRC5D, has shown promising efficacy in pts with RRMM. By simultaneously targeting 2 validated myeloma target antigens, using tec + tal in combination may lead to improved outcomes by overcoming resistance mechanisms, such as antigen escape. Here, we report the first results from the phase 1b RedirecTT-1 trial (NCT04586426) in pts with RRMM. **Methods:** Enrolled pts had MM per International Myeloma Working Group 2016 criteria; were relapsed/refractory or intolerant to the last line of therapy (LOT); were exposed to a proteasome inhibitor, immunomodulatory drug, and anti-CD38 therapy; and had measurable disease. The primary objectives are to evaluate safety and identify a recommended phase 2 regimen (RP2R) for the combination. Responses were investigator-assessed. Adverse events (AEs) were graded per CTCAE v5.0. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded per ASTCT criteria. **Results:** As of Dec 12, 2022, 63 pts had received tec + tal. Median (range) age was 67 years (39–81); median (range) prior LOT was 5 (1–11); 33% (15/45) had high-risk cytogenetics; 78% (49/63) were triple-class refractory; 63% (40/63) were penta-drug exposed; and 43% (27/63) had extramedullary disease (EMD; all bone independent). Median (range) duration of follow-up was 14.4 months (0.5–21.9). The most common treatment-emergent AEs were CRS (81%; grade [gr] 3, 3%, no gr 4), neutropenia (76%; gr 3/4, 75%), and anemia (60%; gr 3/4, 43%). Dose-limiting toxicities (DLTs) were reported at dose level 1 (gr 3 herpetic stomatitis) and dose level 3 (gr 3 AST/ALT elevation). 1 ICANS event was reported at dose level 3. No DLTs were reported at the RP2R. Across all dose levels, overall response rate (ORR) was 84% (52/62) among all evaluable pts and 73% (19/26) among evaluable pts with EMD; rate of complete response or better (≥CR) was 34% (21/62) and 31% (8/26), respectively. At the RP2R, ORR was 92% (12/13) among all evaluable pts and 83% (5/6) among evaluable pts with EMD; rate of ≥CR was 31% (4/13) and 33% (2/6), respectively. Median duration of response has not been reached. Updated data, with 19 additional pts at the RP2R, will be presented. **Conclusions:** In this first combination study of two bispecific antibodies in MM, targeting BCMA and GPRC5D, tec + tal at the RP2R has a manageable safety profile consistent with each of the monotherapies. A 92% ORR was observed in pts with advanced RRMM at the RP2R and an ORR of 83% was achieved in pts with EMD, a high-risk population with unmet need, supporting further evaluation of the combination. © 2023 American Society of Clinical Oncology, Inc. Introduction: With use of combination therapy (Tx), patients (pts) with RRMM become TCE earlier in their disease course and represent a therapeutic challenge. In the phase 3 KarMMa 3 trial (NCT03651128), ide-cel significantly improved median progression-free survival (mPFS 13.3 vs 4.4 mo; HR 0.49; P< 0.001) and overall response rate (ORR 71% vs 42%; P< 0.001) vs standard (std) regimens in pts with TCE RRMM who received 2–4 prior lines of Tx (LoT). We assessed efficacy and safety of ide-cel vs std regimens across numbers (no.) of prior LoT (2, 3, 4, and 3 or 4) in pts with TCE RRMM in KarMMa 3. **Methods:** Pts with RRMM who received 2–4 prior LoT, were TCE (immunomodulatory agents, proteasome inhibitors, and daratumumab), and had disease refractory to the last regimen were randomized 2:1 to receive ide-cel (range 150–450 x 10^6 CAR+ T cells) or a std regimen (DPd, DVd, IRd, Kd, or EPd); stratification factors included no. of prior LoT (2 vs 3 or 4). Analysis was performed to assess the relationship between soluble BCMA (sBCMA) levels and prior LoT. **Results:** Baseline

Dose-limiting toxicities (DLTs) were reported at dose level 1 (gr 3 herpetic stomatitis) and dose level 3 (gr 3 AST/ALT elevation). 1 ICANS event was reported at dose level 3. No DLTs were reported at the RP2R. Across all dose levels, overall response rate (ORR) was 84% (52/62) among all evaluable pts and 73% (19/26) among evaluable pts with EMD; rate of complete response or better (≥CR) was 34% (21/62) and 31% (8/26), respectively. At the RP2R, ORR was 92% (12/13) among all evaluable pts and 83% (5/6) among evaluable pts with EMD; rate of ≥CR was 31% (4/13) and 33% (2/6), respectively. Median duration of response has not been reached. Updated data, with 19 additional pts at the RP2R, will be presented. **Conclusions:** In this first combination study of two bispecific antibodies in MM, targeting BCMA and GPRC5D, tec + tal at the RP2R has a manageable safety profile consistent with each of the monotherapies. A 92% ORR was observed in pts with advanced RRMM at the RP2R and an ORR of 83% was achieved in pts with EMD, a high-risk population with unmet need, supporting further evaluation of the combination. © 2023 American Society of Clinical Oncology, Inc. Introduction: With use of combination therapy (Tx), patients (pts) with RRMM become TCE earlier in their disease course and represent a therapeutic challenge. In the phase 3 KarMMa 3 trial (NCT03651128), ide-cel significantly improved median progression-free survival (mPFS 13.3 vs 4.4 mo; HR 0.49; P< 0.001) and overall response rate (ORR 71% vs 42%; P< 0.001) vs standard (std) regimens in pts with TCE RRMM who received 2–4 prior lines of Tx (LoT). We assessed efficacy and safety of ide-cel vs std regimens across numbers (no.) of prior LoT (2, 3, 4, and 3 or 4) in pts with TCE RRMM in KarMMa 3. **Methods:** Pts with RRMM who received 2–4 prior LoT, were TCE (immunomodulatory agents, proteasome inhibitors, and daratumumab), and had disease refractory to the last regimen were randomized 2:1 to receive ide-cel (range 150–450 x 10^6 CAR+ T cells) or a std regimen (DPd, DVd, IRd, Kd, or EPd); stratification factors included no. of prior LoT (2 vs 3 or 4). Analysis was performed to assess the relationship between soluble BCMA (sBCMA) levels and prior LoT. **Results:** Baseline

characteristics and high-risk clinical features were generally balanced across prior LoT in each arm. Proportion of pts with triple-class–refractory (TCR) disease increased and median time to progression on last prior Tx decreased from 2 to 4 prior LoT (ide-cel: 50% to 88% and 9.3 to 5.1 mo, respectively), for both arms. At a median follow-up of 18.6 (range 0.4–35.4) mo, PFS improvement for ide-cel vs std regimens was consistent across prior LoT (HR 0.44–0.58). In pts with 2 and 3 or 4 prior LoT, mPFS with ide-cel was 15.1 and 12.0 mo, vs 4.8 and 4.2 mo with std regimens, respectively. The 12-mo PFS rates in the ide-cel arm were 64%, 54%, 46% in pts with 2, 3, 4 prior LoT, respectively. Ide-cel showed numerically higher ORRs (69–74% vs 35–51%) and complete response rates (34–42% vs 2–13%) vs std regimens regardless of prior LoT. Baseline sBCMA levels were similar in pts with 2 vs 3 or 4 prior LoT in both arms; at nadir, a greater proportion of pts in the ide-cel arm with 2 vs 3 or 4 prior LoT cleared sBCMA level (82% vs 68%; P=0.0238). Proportion of pts who had serious AEs was similar in subgroups by prior LoT (ide-cel 51–55%; std regimens 37–39%) vs the overall population (ide-cel 52%; std regimens 38%). Safety profile of ide-cel including cytokine release syndrome (CRS) was similar across prior LoT. Grade 5 CRS occurred in 1 pt each in the 2 and 3 prior LoT subgroups. Investigator-identified neurotoxicity was lowest in pts with 2 prior LoT (2, 7%; 3 or 4, 19%). **Conclusions:** Across prior LoT, the benefit of ide-cel vs std regimens was maintained with consistent safety profile. With increasing LoT, pts were more likely to have TCR disease and numerically poorer efficacy outcomes in both arms. Greater proportion of pts in the ide cel arm with 2 vs 3 or 4 prior LoT had clearance of tumor burden as measured by sBCMA, raising the possibility of earlier ide-cel use in TCE RRMM.

Introduction: With use of combination regimens, including immunomodulatory (IMiD®) agents, proteasome inhibitors (PI) and daratumumab, patients (pts) with RRMM become TCE earlier in their treatment (tx), which represents an unmet need. In KarMMa-3 (NCT03651128), ide-cel significantly improved median progression-free survival (mPFS 13.3 vs 4.4 mo; HR 0.49; P< 0.001) and overall response rates (ORR 71% vs 42%; P< 0.001) vs standard (std) regimens in pts with TCE RRMM (Rodriguez-Otero, NEJM 2023). Efficacy was analyzed in the KarMMa-3 intent-to-treat (ITT) population (pop). Here, we report outcomes in the mITT pop of pts who received the study tx to which they were randomly assigned. **Methods:** Pts with RRMM who received 2–4 prior lines of therapy, were TCE (IMiD agents, PI, and daratumumab), and had disease refractory to the last regimen, were randomized 2:1 to receive ide-cel or a std regimen (DPd, DVd, IRd, Kd or EPd). Efficacy (PFS and ORR) and safety were assessed in the mITT pop who received the study tx to which they were randomly assigned. **Results:** Of the 386 pts in the ITT pop, 351 received study tx and constituted the mITT pop (225 pts, ide-cel; 126 pts, std regimens); 35 randomized pts in the ITT pop did not receive ide-cel (n=29) or std regimens (n=6). Of the 29 pts who did not receive ide-cel, 5 did not undergo leukapheresis and 24 underwent leukapheresis but did not receive ide-cel due to physician decision (n=7), eligibility criteria (n=6), death (n=4), adverse events (AEs; n=4), and manufacturing failure (n=3). Six pts did not receive std regimens (consent withdrawal [n=3], physician decision [n=2], and progressive disease [PD; n=1]). In the mITT pop, baseline characteristics were generally balanced between tx arms, and comparable to the ITT pop. Among pts who did not receive ide-cel (n=29), a greater proportion had high-risk features vs the mITT pop (R-ISS stage III [38% vs 9%] and higher tumor burden [52% vs 25%]). In the mITT pop, tx with ide-cel led to longer PFS vs std regimens (mPFS [95% CI], 14.5 [12.2–17.3] vs 4.4 [3.4–5.9] mo; HR 0.43; 95% CI 0.33–0.56). ORR was higher with ide-cel vs std regimens (80% vs 44%), with higher rates of deep response (≥complete response: 44% vs 6%). In the mITT pop, grade 3/4 AEs occurred in 213/225 (95%) and 94/126 (75%) pts in the ide-cel and std regimens arms, respectively; most commonly neutropenia (80% vs 40%), anemia (51% vs 18%) and thrombocytopenia (44% vs 17%). Grade 5 AEs occurred in 12% and 6% of pts, of which 4.9% and 2.4%, respectively, were due to PD. **Conclusions:** In the mITT pop, the benefit of ide-cel over std regimens was consistent with the ITT pop; while the mPFS for std regimens remained same in both pop, the mPFS for ide-cel was longer in the mITT pop than in the ITT pop, reflecting ide-cel efficacy in infused pts.

characteristics and high-risk clinical features were generally balanced across prior LoT in each arm. Proportion of pts with triple-class–refractory (TCR) disease increased and median time to progression on last prior Tx decreased from 2 to 4 prior LoT (ide-cel: 50% to 88% and 9.3 to 5.1 mo, respectively), for both arms. At a median follow-up of 18.6 (range 0.4–35.4) mo, PFS improvement for ide-cel vs std regimens was consistent across prior LoT (HR 0.44–0.58). In pts with 2 and 3 or 4 prior LoT, mPFS with ide-cel was 15.1 and 12.0 mo, vs 4.8 and 4.2 mo with std regimens, respectively. The 12-mo PFS rates in the ide-cel arm were 64%, 54%, 46% in pts with 2, 3, 4 prior LoT, respectively. Ide-cel showed numerically higher ORRs (69–74% vs 35–51%) and complete response rates (34–42% vs 2–13%) vs std regimens regardless of prior LoT. Baseline sBCMA levels were similar in pts with 2 vs 3 or 4 prior LoT in both arms; at nadir, a greater proportion of pts in the ide-cel arm with 2 vs 3 or 4 prior LoT cleared sBCMA level (82% vs 68%; P=0.0238). Proportion of pts who had serious AEs was similar in subgroups by prior LoT (ide-cel 51–55%; std regimens 37–39%) vs the overall population (ide-cel 52%; std regimens 38%). Safety profile of ide-cel including cytokine release syndrome (CRS) was similar across prior LoT. Grade 5 CRS occurred in 1 pt each in the 2 and 3 prior LoT subgroups. Investigator-identified neurotoxicity was lowest in pts with 2 prior LoT (2, 7%; 3 or 4, 19%). **Conclusions:** Across prior LoT, the benefit of ide-cel vs std regimens was maintained with consistent safety profile. With increasing LoT, pts were more likely to have TCR disease and numerically poorer efficacy outcomes in both arms. Greater proportion of pts in the ide cel arm with 2 vs 3 or 4 prior LoT had clearance of tumor burden as measured by sBCMA, raising the possibility of earlier ide-cel use in TCE RRMM.

Real world evaluation of teclistamab in patients with RRMM: results from the IMF immunotherapy database project

Yi Lin[1], Sireesha Asoori Maringanti[2], Efstathios Kastritis[3], Joaquín Martínez-López[4], Larissa Argenau Marques Brunaldi[5], Radhika Bansal[5], Despina Fotiou[3], Magdelana Corona[6], Reyes Mas[6], Andre De Menezes Silva Corraes[5], Prashant Kapoor[5], Meletios Dimopoulos[3], Andre Tamayo[6], Sikander Ailawadhi[5], Ricardo Parrondo[5], Brian Durie[7], Thomas Martin[2]

[1]Mayo Clinic, Rochester, MN, USA; [2]University of California, San Francisco; [3]National and Kapodistrian University of Athens/ Department of Clinical Therapeutics; [4]Hematología Hospital 12 de Octubre, Madrid, Spain; [5]Mayo Clinic; [6]Hematology Department, Complutense University, Madrid, Spain; [7]Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, CA

Introduction: Teclistamab (TEC) is a bispecific BCMA-CD3 directed T-cell antibody (BsAb), which received EMA approval on 8/24/22 and subsequent FDA approval on 10/25/22, based on the MajesTEC-1 study showing high single agent response rates (≥PR in 63.0%) in heavily pretreated patients with relapsed/refractory multiple myeloma (RRMM). Also reported were unique side effects including, cytokine release syndrome (CRS) and neurotoxicity (ICANS), and prompting the FDA/EMA to recommend inpatient monitoring during the initial step-up and first full-dose of TEC. In addition, a high incidence of infections (76.4%; ≥grade 3: 44.8%) have been reported. Thus, the IMF Immunotherapy subgroup embarked on this international analysis of real-word use of Teclistamab in RRMM. **Methods:** Patients treated with Teclistamab at 6 academic centers from 3 countries (US, Greece, Spain), were included. Data was collected up until May 23, 2023. **Results:** 77 patients were included in this analysis; median age was 69 (range 38-91y); 16 pts. (21%) were >75 yrs; 53% male, 68% Caucasian, 15% Hispanic, and 14% Asian. Pts received a median of 6 PLT (range 1-21); 75% were triple-class-refractory (n=44/59), 23% had high-risk cyto/fish and 32% had 1q21 gain. At least 59% of pts would not have been eligible for MajesTEC-1 (51% prior BCMA (n=26 BCMA-CAR, n=8 BCMA-ADC; n=2 BCMA-bisp; n=3 Car+ADC); 13% had CrCl < 30ml/min with 2 on HD). Median number of hospital days was 7 but 26 patients were treated entirely as outpatients (Mayo clinic Rochester and Arizona). CRS was seen in 52% (all grade 1: except 1Gr2, 1Gr4); it generally resolved within 24 hours and was managed with either 1 dose of tocilizumab or 1-4 doses of dex. CRS was more common in patients treated in the inpatient versus outpatient (CRS 64% vs. 35%) setting. CrCl < 30 mls, did not appear to alter the incidence or severity of CRS (55%; all Gr1). ICANS was infrequent (n=5; 7%, 1 pt with Gr 4-Sz requiring HD-steroids and treatment discontinuation). Infections were common, seen in 37% of patients, and the majority of infections were reported as viral URI or CMV reactivation. No CMV organ disease and no Covid deaths occurred. The overall response rate for evaluable patients (n=56) was 61%; (sCR/CR 7; VGPR 19; PR 8; SD 11; PD 11). In pts treated with prior BCMA (n=32) the ORR was 59% (sCR 1; VGPR 14; PR 4; SD 6; PD 7). The most common reason for treatment discontinuation was PD (12%). **Conclusions:** In this Real-World evaluation of Teclistamab, a high ORR was seen 61%, similar to the results of the MajesTEC-1 study. Responses were rapid and are expected to deepen over time (median f/u only 3m). CRS rates were similar to MajesTEC-1 and no unexpected toxicity was noted. Infection rates were low but may increase with longer follow-up. Details regarding the timing and types of infection and the global use of IVIG will be presented. Additional patient data will be presented at the IMS meeting from global IMWG centers.

Thus, the IMF Immunotherapy subgroup embarked on this international analysis of real-word use of Teclistamab in RRMM. **Methods:** Patients treated with Teclistamab at 6 academic centers from 3 countries (US, Greece, Spain), were included. Data was collected up until May 23, 2023. **Results:** 77 patients were included in this analysis; median age was 69 (range 38-91y); 16 pts. (21%) were >75 yrs; 53% male, 68% Caucasian, 15% Hispanic, and 14% Asian. Pts received a median of 6 PLT (range 1-21); 75% were triple-class-refractory (n=44/59), 23% had high-risk cyto/fish and 32% had 1q21 gain. At least 59% of pts would not have been eligible for MajesTEC-1 (51% prior BCMA (n=26 BCMA-CAR, n=8 BCMA-ADC; n=2 BCMA-bisp; n=3 Car+ADC); 13% had CrCl < 30ml/min with 2 on HD). Median number of hospital days was 7 but 26 patients were treated entirely as outpatients (Mayo clinic Rochester and Arizona). CRS was seen in 52% (all grade 1: except 1Gr2, 1Gr4); it generally resolved within 24 hours and was managed with either 1 dose of tocilizumab or 1-4 doses of dex. CRS was more common in patients treated in the inpatient versus outpatient (CRS 64% vs. 35%) setting. CrCl < 30 mls, did not appear to alter the incidence or severity of CRS (55%; all Gr1). ICANS was infrequent (n=5; 7%, 1 pt with Gr 4-Sz requiring HD-steroids and treatment discontinuation). Infections were common, seen in 37% of patients, and the majority of infections were reported as viral URI or CMV reactivation. No CMV organ disease and no Covid deaths occurred. The overall response rate for evaluable patients (n=56) was 61%; (sCR/CR 7; VGPR 19; PR 8; SD 11; PD 11). In pts treated with prior BCMA (n=32) the ORR was 59% (sCR 1; VGPR 14; PR 4; SD 6; PD 7). The most common reason for treatment discontinuation was PD (12%). **Conclusions:** In this Real-World evaluation of Teclistamab, a high ORR was seen 61%, similar to the results of the MajesTEC-1 study. Responses were rapid and are expected to deepen over time (median f/u only 3m). CRS rates were similar to MajesTEC-1 and no unexpected toxicity was noted. Infection rates were low but may increase with longer follow-up. Details regarding the timing and types of infection and the global use of IVIG will be presented. Additional patient data will be presented at the IMS meeting from global IMWG centers.

Introduction: ALNUC, a 2+1 T-cell engager (TCE) with bivalent binding to BCMA, demonstrated clinical activity in RRMM in a phase 1 study (NCT03486067). IV ALNUC had a long duration of response (DOR) but resulted in cytokine release syndrome (CRS) in 76% of pts. Subcutaneous (SC) dosing reduced

CRS rate and severity, allowing higher target doses with promising antitumor activity. We present long-term data from IV pts and safety and efficacy in SC pts treated in the phase 1 study. **Methods:** Pts had ≥3 prior lines of therapy (LOTs), including an immunomodulatory drug, a proteasome inhibitor, and an anti-CD38 therapy. IV ALNUC was given at target doses of 0.15–10 mg with both fixed and step-up dosing (Costa LJ et al. Blood 2019). SC ALNUC was given on D 1, 4, 8, 15, and 22 of cycle 1 (C1), QW in C2–3, Q2W in C4–6, and Q4W in C7+ (28-d cycles). Step-up doses were given on C1D1 (3 mg) and C1D4 (6 mg), and target doses (≥10 mg) on C1D8 and thereafter. Safety and tolerability were primary objectives. Data cutoff was Nov 9 2022. **Results:** In total, 70 pts received IV ALNUC. Overall response rate (ORR) was 39% (27/70); median DOR was 33.6 mo (95% CI, 10.6–NA). Median PFS was 3.1 mo (95% CI, 1.9–5.5). CRS was reported in 53 (76%) pts, with grade (G) ≥3 in 5 (7%) pts. Of 73 pts treated with SC ALNUC in dose escalation (target dose: 10 mg, 6; 15 mg, 4; 30 mg, 6; 60 mg, 7) and dose expansion (target dose: 10 mg, 19; 30 mg, 21; 60 mg, 10), median age was 64 y; 42% were female. Pts had a median of 4 prior regimens; 93% were refractory to last LOT, 100%/63% had triple-class exposed/refractory MM; 66%/26% had penta-drug exposed/refractory MM. Median follow-up was 4.3 mo (range, 0.5–16.0); 39 (53%) pts were on treatment at data cutoff. Any-G/G3–4 treatment-emergent adverse events occurred in 99%/79% of SC pts; most common were CRS (56%/0%), neutropenia (49%/42%), infections (47%/10%), anemia (41%/25%), and thrombocytopenia (33%/14%). SC pts had CRS limited to G1 (44%) or G2 (12%); 35 pts received ≥1 concomitant medication for CRS, including tocilizumab (30%) and/or corticosteroids (15%). Median time to CRS was 3 d (range, 1–20); median duration was 2 d (range, 1–11). SC ALNUC bioavailability was ~61%; t½ was 15 d. Trough concentrations at the 30-mg target dose exceeded levels predicted for efficacy by C2D1. In 55 efficacy-evaluable pts receiving SC ALNUC, ORR was 53% across all doses and 65% at the 30-mg target dose; 20/29 responders were minimal residual disease (MRD)-evaluable, of whom 16 (80%) were MRD-negative (10e-5 sensitivity) at C2D1 or C4D1. Median time to response was 1.0 mo (95% CI, 0.7–1.3); 25 responses (86%) were ongoing. **Conclusions:** IV ALNUC led to durable responses in heavily pretreated pts with RRMM. SC ALNUC had an improved safety profile vs IV ALNUC, with CRS limited to low-grade, short-lived events. SC ALNUC showed promising dose-dependent antitumor activity and a high proportion of responders were MRD-negative. The phase 1 study is ongoing. Presented at EHA 2023. Wong SW et al. Abstract P883.

Introduction: Teclistamab is a bispecific t-cell engaging (BiTE) therapy that was approved by the US FDA in October 2022 for treatment of relapsed and refractory multiple myeloma (RRMM) in patients who have received ≥ 4 lines of therapy. We report our initial experience with commercial teclistamab use at the Dana-Farber Cancer Institute/Brigham and Women's Hospital. **Methods:** Patients treated with teclistamab until April 15, 2023 were included in the analysis. Data was collected for baseline demographics, prior therapies, efficacy including response rates (ORR), and safety variables such as rates of cytokine release syndrome (CRS), neurological toxicity (NT), cytopenias and infectious complications. **Results:** 34 patients were treated with teclistamab from December 15, 2022 to April 15, 2023. The median age was 65 (range 51-83), with 10 females (29%) and 24 males (71%). Median prior lines of therapy was 6 (range 4-12) with 55% of patients having had a prior stem cell transplant. Seven patients (21%) had received prior BCMA-directed CAR-T therapy and 10 (29%) had received prior BCMA-targeting antibody-drug conjugate therapy. Twenty-one patients (62%) had at least one high-risk (HR) cytogenetic risk factor among del 17p, t(4;14), t(14;16) or 1q21 gain or amplification with breakdown as follows: 1 HR factor: 11 (32%), 2 HR factors: 9 (26%), 3 HR factors: 1 (3%). Eight patients (24%) had a creatinine clearance < 40 ml/min. Thirteen patients (38%) treated had extramedullary disease (EMD) and 5 (15%) had CNS involvement. Hematologic toxicity included anemia (n=34, 100%, grade ≥3; 62%), neutropenia (n=24, 71%, grade ≥3; 47%), and thrombocytopenia (n=31, 91%, grade ≥3; 53%) with most present prior to treatment. CRS was reported in 19 patients (56%), 12 with grade 1 (35%), 7 with grade 2 (21%) and none with grade 3 or higher. Tocilizumab was used in 8 patients (24%) and dexamethasone was used in 4 patients (12%). Grade 1 neurotoxicity was assessed in 1 patient (3%), which did not require treatment. Eleven (32%) infectious complications were observed with 3 (9%) patients presenting with grade 3 or greater infections requiring hospitalization or urgent intervention, all non-fatal. At a median follow-up of 6 weeks, ORR is 44%, with 3 patients (9%) achieving a complete response (CR), and 10 (29%) achieving VGPR or greater. Thirteen patients have had disease progression or died at the time of data cut-off (38%). The ORRs of those with renal dysfunction (CrCl < 40 ml/min), EMD or ≥1 HR cytogenetic risk factor is 25%, 23% and 48%, respectively. ORR in patients with prior BCMA-targeted therapy exposure is 27%. **Conclusions:** Overall, we observed that teclistamab treatment in a commercial setting generated comparable responses to the previously reported clinical trials without any new toxicity signals. While additional follow up with commercial Teclistamab use in the real-world is needed to validate these results, this study reveals the need for efficacious therapies in high-risk or ultra-high-risk disease.

CRS rate and severity, allowing higher target doses with promising antitumor activity. Real world single center expeirence of long-term toxicities with anti-BCMA CAR T-cell therapy in relapsed and refractory multiple myeloma

Patrick Costello[1], Jacob Laubach[1], Clifton Mo[1], Adam Sperling[1], Sarah Nikiforow[1], Robert Redd[1], Linda Ramsdell[1], Kathleen Finn[1], Lauren Desnoyers[1], Michelle Denisco[1], Esther Fraser[1], Giada Bianchi[2], Monique Hartley-Brown[1], Irene Ghobrial[1], Paul Richardson[1], Kenneth Anderson[3], Nikhil Munshi[4], Omar Nadeem[1], Shonali Midha[1]

[1]Dana Farber Cancer Institute; [2]Brigham and Women/s Hospital/ Harvard Medical School/Dana Farber Cancer Institute; [3]LeBow Institute for Myeloma Therapeutics and Jerome Lipper Center for Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts; [4]Dana-Farber Cancer Institute, Boston, MA, USA, Veterans Affairs Boston Healthcare System/Harvard Medical School

Introduction: Anti-BCMA CAR T-cell therapy is approved for relapsed and refractory multiple myeloma (RRMM) with two available products (idecabtagene vicleucel, ide-cel and ciltacabtagene autoleucel, cilta-cel). Data regarding long-term toxicities in a real-world population is lacking. We report long-term toxicities in patients treated with ide-cel or cilta-cel at Dana-Farber Cancer Institute/Brigham and Women's Hospital. **Methods:** Patients who received an anti-BCMA CAR T-cell infusion for RRMM between 8/9/2021 – 2/22/23 were retrospectively analyzed. Toxicities were divided into early (90d). **Results:** Fifty-four patients, median age 66 yrs. (34-79) received cilta-cel (n = 7, 13%) or ide-cel (n = 47, 87%) and were followed for median 158 days (range 29-395). Median number of prior regimens was 8 (3-15). A total of 13 patients (24%) received prior belantamab mafodotin (blmf). Bridging therapy was used in 41 (76%) patients with most receiving alkylator therapy and 4 on continued blmf. Cytokine release syndrome (CRS) was reported in 76% of patients (G1: n=30, 56%; G2: n=11, 20%) and neurotoxicity in 4 patients (G1: n=2, 7%; G2: n=2, 4%; grade 2: n=2, 4%,). Any-grade cytopenias included: anemia (n=51, 94%), thrombocytopenia (n=45, 83%) and neutropenia (n=45, 83%). Grade ≥3 (high-grade) early cytopenias included neutropenia (n=14, 26%; G3: 19%, G4: 7%) thrombocytopenia (n=13, 24%; G3: 13%, G4: 11%) and anemia (G3: n=1, 2%). High-grade late cytopenias included thrombocytopenia (n=14, 26%; G3: 19%, G4: 7%), neutropenia (n=13, 24%; G3: 13%, G4: 11%) and anemia (G3: n=3, 6%). High-grade prolonged cytopenias included neutropenia (G3: n=6, 11%), thrombocytopenia (n=6, 11%; G3: 7%, G4: 4%), and anemia (G3: n=2, 4%). Ten patients (19%) had one or more prolonged high-grade cytopenias; the median age of patients who recovered counts was 60 (n=5, 50%) versus 74 for those who did not (n=5, 50%). Supportive care for all 10 patients included: IVIg (50%), G-CSF (40%), darbepoeitin alfa (40%), and romiplostim (30%). Eleven patients (20%), median age 68 yrs. (51-75) developed nonfatal infections, with 5 requiring hospitalization. Most common infections involved the respiratory tract (n=9, 17%); 5 patients with COVID-19 and 4 with pneumonia. A total of 41 patients (76%) had hypogammaglobulinemia (< 600 mg/dL), including 9 of the 11 patients (82%) with infections. No treatment related deaths or myeloid neoplasms were observed. Overall response rate was 85% (n=46) with 65% (n=35) achieving a very good partial response or better, including 26% (n=14) with a complete response. A total of 25 patients (46%) had either progressive disease or started new therapy at data cutoff with 12 deaths due to progression. **Conclusions:** This analysis reports less frequent high-grade cytopenias as compared to previous clinical trial data. Number of prior therapies, bridging regimens, and CRS were not found to be predictive of prolonged toxicity.

Introduction: Chimeric antigen receptor (CAR) T-cell therapies targeting B cell maturation antigen (BCMA) have shown deep response in RRMM but new targets are needed as most patients (pts) relapse. GPRC5D, an orphan receptor expressed on MM cells with limited expression in other tissues, is a promising therapeutic target for MM. We present safety and efficacy from the Part A dose escalation of CC-95266-MM-001 (NCT04674813), a phase 1, first-in-human, multicenter open-label study of BMS-986393 (CC-95266), a GPRC5D-targeted autologous CAR T-cell therapy, in pts with RRMM. **Methods:** Part A included pts with ≥3 prior lines of therapy, with prior BCMA-directed and CAR T-cell therapies allowed. After leukapheresis and lymphodepletion, pts had a single infusion of BMS-986393. Safety, maximum tolerated dose (MTD), and/or recommended phase 2 dose were primary objectives. **Results:** As of 7 Sept 2022, 33/40 enrolled pts received BMS-986393 at doses of 25, 75, 150, 300, and 450 × 10^6 CAR T cells. Of these, 48% had high-risk cytogenetics and 45% had extramedullary plasmacytomas. Eighteen (55%) pts had received prior BCMA-targeted therapies, including BCMA-directed CAR T-cell therapy (13 pts); 24% had penta-refractory MM. Grade (G) 3/4 treatment-emergent adverse events (TEAEs) occurred in 24/33 (73%) pts; most frequently

We report long-term toxicities in patients treated with ide-cel or cilta-cel at Dana-Farber Cancer Institute/Brigham and Women's Hospital. **Methods:** Patients who received an anti-BCMA CAR T-cell infusion for RRMM between 8/9/2021 – 2/22/23 were retrospectively analyzed. Toxicities were divided into early (90d). **Results:** Fifty-four patients, median age 66 yrs. (34-79) received cilta-cel (n = 7, 13%) or ide-cel (n = 47, 87%) and were followed for median 158 days (range 29-395). Median number of prior regimens was 8 (3-15). A total of 13 patients (24%) received prior belantamab mafodotin (blmf). Bridging therapy was used in 41 (76%) patients with most receiving alkylator therapy and 4 on continued blmf. Cytokine release syndrome (CRS) was reported in 76% of patients (G1: n=30, 56%; G2: n=11, 20%) and neurotoxicity in 4 patients (G1: n=2, 7%; G2: n=2, 4%; grade 2: n=2, 4%,). Any-grade cytopenias included: anemia (n=51, 94%), thrombocytopenia (n=45, 83%) and neutropenia (n=45, 83%). Grade ≥3 (high-grade) early cytopenias included neutropenia (n=14, 26%; G3: 19%, G4: 7%) thrombocytopenia (n=13, 24%; G3: 13%, G4: 11%) and anemia (G3: n=1, 2%). High-grade late cytopenias included thrombocytopenia (n=14, 26%; G3: 19%, G4: 7%), neutropenia (n=13, 24%; G3: 13%, G4: 11%) and anemia (G3: n=3, 6%). High-grade prolonged cytopenias included neutropenia (G3: n=6, 11%), thrombocytopenia (n=6, 11%; G3: 7%, G4: 4%), and anemia (G3: n=2, 4%). Ten patients (19%) had one or more prolonged high-grade cytopenias; the median age of patients who recovered counts was 60 (n=5, 50%) versus 74 for those who did not (n=5, 50%). Supportive care for all 10 patients included: IVIg (50%), G-CSF (40%), darbepoeitin alfa (40%), and romiplostim (30%). Eleven patients (20%), median age 68 yrs. (51-75) developed nonfatal infections, with 5 requiring hospitalization. Most common infections involved the respiratory tract (n=9, 17%); 5 patients with COVID-19 and 4 with pneumonia. A total of 41 patients (76%) had hypogammaglobulinemia (< 600 mg/dL), including 9 of the 11 patients (82%) with infections. No treatment related deaths or myeloid neoplasms were observed. Overall response rate was 85% (n=46) with 65% (n=35) achieving a very good partial response or better, including 26% (n=14) with a complete response. A total of 25 patients (46%) had either progressive disease or started new therapy at data cutoff with 12 deaths due to progression. **Conclusions:** This analysis reports less frequent high-grade cytopenias as compared to previous clinical trial data. Number of prior therapies, bridging regimens, and CRS were not found to be predictive of prolonged toxicity.

Introduction: Chimeric antigen receptor (CAR) T-cell therapies targeting B cell maturation antigen (BCMA) have shown deep response in RRMM but new targets are needed as most patients (pts) relapse. GPRC5D, an orphan receptor expressed on MM cells with limited expression in other tissues, is a promising therapeutic target for MM. We present safety and efficacy from the Part A dose escalation of CC-95266-MM-001 (NCT04674813), a phase 1, first-in-human, multicenter open-label study of BMS-986393 (CC-95266), a GPRC5D-targeted autologous CAR T-cell therapy, in pts with RRMM. **Methods:** Part A included pts with ≥3 prior lines of therapy, with prior BCMA-directed and CAR T-cell therapies allowed. After leukapheresis and lymphodepletion, pts had a single infusion of BMS-986393. Safety, maximum tolerated dose (MTD), and/or recommended phase 2 dose were primary objectives. **Results:** As of 7 Sept 2022, 33/40 enrolled pts received BMS-986393 at doses of 25, 75, 150, 300, and 450 × 10^6 CAR T cells. Of these, 48% had high-risk cytogenetics and 45% had extramedullary plasmacytomas. Eighteen (55%) pts had received prior BCMA-targeted therapies, including BCMA-directed CAR T-cell therapy (13 pts); 24% had penta-refractory MM. Grade (G) 3/4 treatment-emergent adverse events (TEAEs) occurred in 24/33 (73%) pts; most frequently

neutropenia (61%), anemia (21%) and thrombocytopenia (21%). On-target off-tumor TEAEs, all G1, included skin TEAEs (30%), dysgeusia (15%), nail TEAEs (9%) and dysphagia (3%). Dose-limiting toxicities of prolonged (out to day 42) G4 neutropenia and/or thrombocytopenia occurred in 2 pts; MTD was not exceeded. Cytokine release syndrome (CRS) occurred in 21/33 pts (19 G1/2; 2 G3). Immune effector cell-associated neurotoxicity syndrome (ICANS)–type neurotoxicity occurred in 2 pts and was low-grade and reversible with steroid treatment. Overall response rate was 89% (17/19) in efficacy-evaluable pts, including 7/9 pts with prior BCMA-directed therapies including CAR T cells. Median follow-up for treated pts was 3.1 mo (range, 0.1–15.5). At data cutoff, 15/17 pts with a response were ongoing. All 4 pts with available minimal residual disease (MRD) data and best overall response of complete response (CR) were MRD-negative (10^{-5} depth) at 3 mo. BMS-986393 reduced soluble BCMA levels across all dose levels; BMS-986393 exposure showed dose-dependence. **Conclusions:** As of data cutoff, dose escalation of BMS-986393 from 25–450 × 10^6 CAR T cells did not exceed MTD. CRS was mostly G1/2. ICANS-type neurotoxicity was infrequent, low-grade and reversible. A minority of pts had on-target off-tumor TEAEs, all G1. BMS-986393 showed durable responses and efficacy at all tested dose levels, including MRD-negative CRs and in pts previously exposed to BCMA-directed therapies. These preliminary data support GPRC5D-directed CAR T-cell therapy with BMS-986393 for treating RRMM, irrespective of prior BCMA-directed therapy. Part B dose expansion is underway. Updated data will be reported. Presented at EHA 2023. Abst S193.

[1]Department of Medicine, Memorial Sloan Kettering Cancer Center; [2]Memorial Sloan Kettering Cancer Senter; [3]Mount Sinai Morningside/West, Icahn School of Medicine, Mount Sinai; [4]Bone Marrow Transplant and Cellular Therapy, Memorial Sloan Kettering Cancer Center, New York City NY, USA; [5]Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: CAR-T cell therapy has been approved for patients with RRMM and 4 or more prior lines of therapy. Due to multiple prior treatments, some patients have a low absolute lymphocyte count (ALC) and data on the prognostic impact of pre-therapy ALC is conflicting. This real-world analysis investigated pre-apheresis (A) and pre-lymphodepletion (LD) ALC, and the ALC reduction between A and LD, on survival outcomes post CAR-T for RRMM. **Methods:** This was a single center, retrospective analysis of 88 patients with RRMM who received CAR-T cell therapy between March 2017 and December 2022. Both commercial (n=22) (BCMA-directed), and investigational (n=66) (BCMA- or GPRC5D-directed) CAR-T were included. We assessed the impact of Pre-A and Pre-LD ALC as well as the reduction in ALC (measured as the difference between pre-LD and pre-A ALC) on the progression-free survival (PFS) and overall survival (OS) using the Cox proportional hazard models. **Results:** The median age was 60 years (range, 37–79), of whom 52% were male. The median number of prior lines of therapy was 7 (range: 2–20). Extramedullary disease (EMD) was present in 51%, and 52% of patients received bridging therapy. The median pre-A and pre-LD ALC was 0.7×10^9/L (range, 0.1–3.4) and 0.7×10^9/L (range, 0.1–3.1), respectively. The median absolute reduction in ALC was 0.0 (range, -2.7 to 2.3). Using the lowest quartiles, low pre-A ALC and low pre-LD ALC were defined as ≤ 0.5×109/L and ≤ $0.4x10^9$/L, respectively. A high reduction was set ≥ 0.27×10^9/L, as described in a prior study. The median follow-up duration post CAR-T infusion was 24 months. There was no significant difference in PFS with either a low vs. high pre-A ALC (HR 1.52, 95% CI 0.92–2.50, p=0.11), low vs. high pre-LD ALC (HR 1.57, 95%CI 0.93–2.68, p=0.10), or a high absolute reduction in ALC between these timepoints (HR 1.39, 95%CI 0.82–2.36, p=0.24). On multivariate analysis, only EMD, high-risk cytogenetics, and ECOG-score of 1/2 were independently associated with a significantly inferior PFS. Regarding OS, on univariate analysis, low pre-LD ALC was significantly associated with a shorter OS (median OS, 13 vs. 29 months, HR 0.47, 95% CI 0.24–0.92, p=0.032), as was presence of EMD, double refractory status, and Revised-International Staging System (R-ISS) of 2/3. Low pre-A ALC and a high absolute reduction in ALC between A and LD (≥0.27) had no significant impact on OS. On multivariate analysis, only EMD was associated with a significantly shorter OS (HR 4.17, 95% CI 1.96–8.87, p< 0.001). **Conclusions:** On multivariate analysis, the pre-A, -pre-LD, and the absolute reduction in ALC prior to CAR-T administration had no significant impact on either PFS or OS. Inferior survival outcomes post-CAR-T appear to be driven by previously recognized factors like the presence of EMD, high-risk cytogenetics, and reduced baseline performance status. Of note, all patients had an ALC > $0.1x10^9$/L and the impact of pre-treatment ALC below this level cannot be assessed from this analysis.

Introduction: Vitamin D (VitD) deficiency is a potentially modifiable risk factor for poor outcomes in relapsed/refractory multiple myeloma (RRMM). Recent studies demonstrated that VitD deficiency may be associated with inferior survival in recipients of autologous stem-cell transplant (ASCT) (Eicher, Hem Onc, 2020). Additionally, we previously demonstrated that VitD insufficiency is associated with inferior clinical outcomes in patients with B-cell lymphoma treated with CD19-directed chimeric antigen receptor T-cell therapy (CAR-T) (Nath, TCT, 2022). The role of circulating vitamin D in patients with RRMM treated with CAR-T is currently unknown. Here, we evaluated the impact of vitamin D status on clinical outcomes in this patient population. **Methods:** We performed a single-center, retrospective analysis of adult patients with RRMM who received commercial or investigational CAR-T between 04/2017–09/2022 and had a serum vitamin D (25[OH]D) measured pre-CAR-infusion. Vitamin D deficiency was defined as < 20ng/mL as per the Endocrine Society guidelines. Cox proportional hazards models were used to assess the impact of pre-CAR-T vitamin D status on progression-free survival (PFS) and overall survival (OS). **Results:** Of the 102 patients with RRMM who received CAR-T, 61 patients had a pre-CAR infusion vitamin D level available. The median age of the 61 patients was 62 years (range, 38-79), with 57% males. Patients were heavily pretreated with a median 6 prior lines of therapy (range, 2 – 14), and 97% had a prior ASCT. Triple-class refractoriness (TCR), extramedullary disease (EMD), and high-risk cytogenetics (HRC) were observed in 80%, 52%, and 70% of patients, respectively. Baseline characteristics were overall comparable between vitamin D deficient (< 20ng/mL; n= 11) and vitamin D replete (≥20ng/mL; n=50) patients. On univariate analysis, vitamin D deficient compared to replete patients had a significantly inferior PFS (median PFS, 3.5 months vs. 6.5months, HR of 2.24, 95% Confidence Interval [CI] 1.09-4.59, p=0.041). These differences-maintained significance in a multivariate analysis adjusting for baseline characteristics (age, gender, ECOG performance status, HRC, EMD, penta-refractory status) (HR of 2.53, 95%CI 1.14–5.66, p=0.032). There was no significant difference in OS based on vitamin D status in both the univariate and multivariate analysis. Only EMD and decreased performance status (ECOG 1 or 2) was an independently significant poor prognostic factor for OS. **Conclusions:** In this modest cohort of patients with RRMM, VitD deficiency (< 20ng/mL) prior to CAR-T cell therapy was potentially associated with inferior PFS. However, the small sample size and the possibility of residual confounding precludes concrete conclusions. Future studies with larger cohorts of patients will be needed to confirm these findings.

Introduction: Despite improvements in the treatment landscape of RRMM, outcomes remain poor in patients (pts) with high-risk features such as cytogenetic abnormalities, advanced-disease stage, high tumor burden (HTB), presence of extramedullary plasmacytoma (EMP), and triple-class refractory disease (TCRMM). Ide-cel, a BCMA-directed CAR T cell therapy, significantly improved median progression-free survival (mPFS; 13.3 vs 4.4 mo; HR 0.49; P< 0.001) and overall response rate (ORR; 71 vs 42%; P< 0.001) vs standard (std) regimens in the overall population of pts with TCE RRMM in KarMMa-3 (NCT03651128). Here we assess efficacy and safety of ide-cel vs std regimens in high-risk subgroups in KarMMa-3. **Methods:** In KarMMa-3, pts with RRMM who received 2–4 prior regimens, who were TCE (immunomodulatory agent, proteasome inhibitor [PI], and daratumumab), and had disease refractory to the last regimen, were randomized 2:1 to receive ide-cel (target dose range: 150–450x10^6 CAR+ T cells) or a std regimen (DPd, DVd, IRd, Kd, or EPd, based on prior regimen, per investigator). Efficacy was assessed in high-risk groups including pts with cytogenetic

Introduction: Vitamin D (VitD) deficiency is a potentially modifiable risk factor for poor outcomes in relapsed/refractory multiple myeloma (RRMM). Recent studies demonstrated that VitD deficiency may be associated with inferior survival in recipients of autologous stem-cell transplant (ASCT) (Eicher, Hem Onc, 2020). Additionally, we previously demonstrated that VitD insufficiency is associated with inferior clinical outcomes in patients with B-cell lymphoma treated with CD19-directed chimeric antigen receptor T-cell therapy (CAR-T) (Nath, TCT, 2022). The role of circulating vitamin D in patients with RRMM treated with CAR-T is currently unknown. Here, we evaluated the impact of vitamin D status on clinical outcomes in this patient population. **Methods:** We performed a single-center, retrospective analysis of adult patients with RRMM who received commercial or investigational CAR-T between 04/2017–09/2022 and had a serum vitamin D (25[OH]D) measured pre-CAR-infusion. Vitamin D deficiency was defined as < 20ng/mL as per the Endocrine Society guidelines. Cox proportional hazards models were used to assess the impact of pre-CAR-T vitamin D status on progression-free survival (PFS) and overall survival (OS). **Results:** Of the 102 patients with RRMM who received CAR-T, 61 patients had a pre-CAR infusion vitamin D level available. The median age of the 61 patients was 62 years (range, 38-79), with 57% males. Patients were heavily pretreated with a median 6 prior lines of therapy (range, 2 – 14), and 97% had a prior ASCT. Triple-class refractoriness (TCR), extramedullary disease (EMD), and high-risk cytogenetics (HRC) were observed in 80%, 52%, and 70% of patients, respectively. Baseline characteristics were overall comparable between vitamin D deficient (< 20ng/mL; n= 11) and vitamin D replete (≥20ng/mL; n=50) patients. On univariate analysis, vitamin D deficient compared to replete patients had a significantly inferior PFS (median PFS, 3.5 months vs. 6.5months, HR of 2.24, 95% Confidence Interval [CI] 1.09-4.59, p=0.041). These differences-maintained significance in a multivariate analysis adjusting for baseline characteristics (age, gender, ECOG performance status, HRC, EMD, penta-refractory status) (HR of 2.53, 95%CI 1.14–5.66, p=0.032). There was no significant difference in OS based on vitamin D status in both the univariate and multivariate analysis. Only EMD and decreased performance status (ECOG 1 or 2) was an independently significant poor prognostic factor for OS. **Conclusions:** In this modest cohort of patients with RRMM, VitD deficiency (< 20ng/mL) prior to CAR-T cell therapy was potentially associated with inferior PFS. However, the small sample size and the possibility of residual confounding precludes concrete conclusions. Future studies with larger cohorts of patients will be needed to confirm these findings.

Introduction: Despite improvements in the treatment landscape of RRMM, outcomes remain poor in patients (pts) with high-risk features such as cytogenetic abnormalities, advanced-disease stage, high tumor burden (HTB), presence of extramedullary plasmacytoma (EMP), and triple-class refractory disease (TCRMM). Ide-cel, a BCMA-directed CAR T cell therapy, significantly improved median progression-free survival (mPFS; 13.3 vs 4.4 mo; HR 0.49; P< 0.001) and overall response rate (ORR; 71 vs 42%; P< 0.001) vs standard (std) regimens in the overall population of pts with TCE RRMM in KarMMa-3 (NCT03651128). Here we assess efficacy and safety of ide-cel vs std regimens in high-risk subgroups in KarMMa-3. **Methods:** In KarMMa-3, pts with RRMM who received 2–4 prior regimens, who were TCE (immunomodulatory agent, proteasome inhibitor [PI], and daratumumab), and had disease refractory to the last regimen, were randomized 2:1 to receive ide-cel (target dose range: 150–450x10^6 CAR+ T cells) or a std regimen (DPd, DVd, IRd, Kd, or EPd, based on prior regimen, per investigator). Efficacy was assessed in high-risk groups including pts with cytogenetic

abnormalities (del[17p], t[4;14], or t[14;16]), R-ISS stage III disease, HTB (≥50% CD138+ plasma cells in bone marrow), EMP (soft-tissue-only and soft-tissue bone-related plasmacytomas), and TCRMM (refractory to ≥1 each of an IMiD® agent, a PI, and an anti-CD38 antibody). **Results:** Baseline demographics and disease characteristics were balanced between arms. Median time to progression on the last prior regimen was short in pts treated with both ide-cel vs std regimens in all high-risk subgroups: cytogenetic abnormalities (5.6 vs 6.7 mo), R-ISS stage III disease (3.9 vs 3.5 mo), HTB (5.1 vs 6.2 mo), EMP (5.1 vs 5.1 mo), and TCRMM (5.6 vs 5.8 mo). At a median follow-up of 18.6 mo (range 0.4–35.4), mPFS was longer in pts treated with ide-cel vs std regimens in all high-risk subgroups: cytogenetic abnormalities (11.9 vs 4.2 mo; HR 0.608), R-ISS stage III disease (5.2 vs 3.0 mo; HR 0.861), HTB (11.0 vs 4.9 mo; HR 0.595), EMP (7.2 vs 2.0 mo; HR 0.401), and TCRMM (11.2 vs 3.5 mo; HR 0.458). ORRs (cytogenetic abnormalities [64.5 vs 37.7%], R-ISS stage III [45.2 vs 28.6%], HTB [64.8 vs 52.9%], EMP [55.7 vs 18.8%], and TCRMM [64.0 vs 31.5%]) and complete response rates (CRR; cytogenetic abnormalities [31.8 vs 4.9%], R-ISS stage III [16.1 vs 7.1%], HTB [31.0 vs 8.8%], EMP [23.0 vs 3.1%], and TCRMM [33.5 vs 1.1%]) were improved in pts treated with ide-cel vs std regimens in all high-risk subgroups. Safety data will be presented. **Conclusions:** Pts treated with ide-cel had a lower risk of disease progression or death and higher odds of achieving an overall response (with higher CRRs) vs pts who received std regimens, regardless of baseline high-risk disease. These results support use of ide-cel in pts with TCE RRMM, including those with difficult-to-treat, high-risk disease. Efficacy and safety of BCMA-specific CAR T cell-based therapy in relapsed/refractory multiple myeloma patients with extramedullary disease

Yue Kun Qi[1], Zhenyu Li[1], Kailin Xu[2]

[1]The Affiliated Hospital of XuZhou Medical University; [2]Blood Diseases Institute, Xuzhou Medical University, Xuzhou, Jiangsu, China

Introduction: Relapsed/refractory (R/R) multiple myeloma (MM) patients with extramedullary disease (EMD) have an unfavorable prognosis and no effective treatment. B-cell maturation antigen (BCMA)-specific chimeric antigen receptor (CAR) T-cell therapies have shown promising efficacy in R/R MM; however, data on patients with EMD remain limited. We aimed to assess the efficacy and safety of CAR T-cell therapy in R/R MM patients with EMD. **Methods:** We conducted a retrospective multi-institutional study of 55 R/R MM patients confirmed with EMD at referral. The definition of EMD included (1) soft tissue masses in extraosseous locations resulting from hematogenous spread (EM-E) and (2) bone-related plasmacytomas that extend via disruption of cortical bones into contiguous soft tissues (EM-B). The overall response, long-term outcomes, and safety were assessed. We also characterized differential response between medullary and extramedullary disease, analyzed unique attributes of compartmental toxicity, and explored patterns of relapse in the setting of EMD. **Results:** The infusion resulted in an overall response rate of 90.9% (95% confidence interval [CI], 80.4-96.1) in medullary disease and 70.9% (95% CI, 57.9-81.2) in EMD (P=0.008). Discrepant outcomes between medullary and extramedullary response were observed, with suboptimal and delayed overall response and shortened duration of response in the setting of EMD. With a median follow-up of 27.3 months, the median progression-free survival was 8.7 months (95% CI, 3.7-18.8), and the median overall survival was 16.0 months (95% CI, 13.5-20.1). Local cytokine release syndrome (CRS) was depicted in 21.8% patients and was associated with the occurrence of systemic CRS (r = 0.322; P = 0.017). 80% patients experienced post-infusion progression in EMD, and BCMA+ progression constituted the main pattern of progression in EMD. Landmark analysis was conducted to compare OS in patients who progressed versus remained progression-free at the 6-month landmark time point. We demonstrated that progression before 6 months post-infusion is strongly associated with an increased risk of death (HR = 11.15 [95% CI, 3.49 to 35.60]; P < 0.001). **Conclusions:** Our study shows that anti-BCMA CAR-T therapy has provided apparent therapeutic advantage over the existing drugs in response rate and long-term survival. We describe a discrepancy between medullary and extramedullary response towards CAR T-cell therapy. We suggest that BCMA-specific CAR T cell-based therapy may have limited efficacy in EMD, perhaps due to insufficient expansion and persistence of CAR T cells within the microenvironment.

Introduction: Myeloma patients treated with anti-BCMA bispecific antibodies (bsAb) are at high risk of developing infections due to subsequent depletion of immunoglobulins (IG) and T cell exhaustion. Preventive measures include IG replacement, but no firm recommendations about timing and target levels exist. We aimed to describe early infection incidence, severity, and IgG levels in patients treated with anti-BCMA bsAb. **Methods:** We retrospectively

analyzed patients who received at least one cycle of anti-BCMA bsAB therapy. The parameters of interest included: infection occurrence, onset time of infection, severity, source of infection, microbiological documentation of infection, IgG levels before treatment and after treatment initiation within 30-60 days where available. Infections were graded per CTCAE v 5.0. **Results:** Overall, 32 patients were included in the analysis. Patients received median 0 prior lines of therapy (range 0-4). 29 patients (90,7%) received anti-BCMA as monotherapy, 3 patients (9,3%) as combination with antiCD38 antibody. Overall, 15 patients (47%) of patients experienced an infectious episode within the observation period, 5 (16%) grade 2, 7 (22%) grade 3, 2 (6%) grade 4 and 1 (3%) grade 5. All but one were respiratory tract infections, one was CMV reactivation. Out of 7 microbiologically documented infections, 6 were COVID-19 (omicron era) and one CMV. No patient received IG replacement therapy before the infection onset and 9/15 (60%) patients received IG after an infectious episode. IgG levels before and after treatment were available in 24 patients. One patient had IgG levels below 4 g/L before treatment initiation, whereas 17 (70.8%) patients had IgG below 4 g/L within the first 60 days of treatment initiation. **Conclusions:** Early onset infections are frequent and early IgG drop is present in the majority of patients. Early immunoglobulin replacement should be adopted as a preferable strategy. The possibility of preemptive IG replacement should be evaluated in a prospective manner. COVID-19 remains a significant source of morbidity in patients treated with anti-BCMA bsAb.

Leveraging wearable devices for remote patient monitoring facilitate earlier CRS detection following CAR-T therapy in relapsed/refractory multiple myeloma (RRMM): early results from an IIT

Introduction: Chimeric Antigen Receptor T-cell (CAR-T) therapy includes a prolonged inpatient stay to monitor for cytokine release syndrome (CRS). Shifting the site of care to the outpatient setting may improve patient experience, limit healthcare utilization and decrease costs, but monitoring patients remotely requires reliable CRS detection. The feasibility of using a wearable device for detecting CRS following CAR-T therapy in RRMM was compared to standard of care (SoC) in an investigator initiated clinical trial (IIT). **Methods:** Patients wore a wearable (Current Health Inc.) to collect continuous measures of temperature, pulse, respiratory rate, and O2 saturation in addition to SoC from CAR-T infusion to discharge. Fever was captured as the earliest and consistent marker of CRS per ASTCT criteria. CRS timestamps were tagged in wearable data 1) when pt's temperature breached a fixed threshold of 38C (Tf), and 2) when pt's temperature breached an individualized threshold of 2 standard deviations above their baseline temperature (Ti). Outcomes were time to detection of CRS in wearable data vs. SoC. Adherence was the duration pts wore the wearable over the total monitoring period. **Results:** To date, 24 pts were screened, 22 enrolled (91.7% uptake) and 1 excluded because of concurrent COVID-19. The 21 pts had a total of 41 CRS events - max grades 0 (5 pts), 1 (14 pts), 2 (1 pt), and 3 (1 pt). Patients wore the device for a median of 13 (12-15) days. Median individualized temperature threshold was 37.4 (37-37.6) C. Wearable adherence was 68 (50-81) % and 73 (60 – 88) % for the overall monitoring and high-risk periods, respectively (1 pt had limited data during the high-risk window so was excluded from the comparisons that follow). By temperature thresholds, the wearable detected initial CRS events at a median of 46 (18 - 114) mins earlier than SoC with Tf and a median of 206 (134 - 312) mins earlier than SoC with Ti method. In the no CRS subgroup, false CRS detection occurred in 1 pt with the Tf and 2 pts with the Ti method. There were no missed events. **Conclusions:** Preliminary results suggest that detection of CRS by the wearable device preceded SoC by a median of 126 mins. The breach of individualized temperature thresholds (Ti) facilitated a much earlier detection than breach of fixed thresholds (Tf) which is still earlier than SoC. Earlier detection of CRS affords a lead time to intervene. The low false detection rate is encouraging, and may be evidence of the wearable detecting 'subclinical' events that did not meet ASTCT criteria despite derangement of ≥1 vital signs. The study showcases the utility of continuous vital signs monitoring in capturing CRS, including earlier detection and potentially subclinical events. Reliable CRS monitoring using wearables may help transition workflows to outpatient CAR-T administration. In parallel, correlating early detection of CRS with cytokines drawn in the immediate post CAR-T infusion period is being worked on and will be presented at the meeting.

Introduction: Linvoseltamab is a BCMA×CD3 bispecific antibody (Ab) that has shown promising efficacy and generally manageable safety in patients (pts) with relapsed/refractory multiple myeloma (MM) (Lee et al. ASCO 2023). To optimize dose selection, two Ph 2 dose cohorts (50 and 200 mg) were studied in LINKER-MM1 (NCT03761108). Here, we report a detailed comparison of results from these two cohorts. **Methods:** LINKER-MM1 enrolled adults with MM who progressed on/after ≥3 lines of therapy, including a proteasome inhibitor (PI), an immunomodulatory drug (IMiD), and an anti-CD38 Ab; the Ph 2 portion also included pts who were ≥triple class (PI/IMiD/anti-CD38 Ab) refractory. A protocol amendment permitted pts who progressed during 4–12 wks on 50 mg to escalate to 200 mg. Primary endpoint was objective response rate (ORR). **Results:** This analysis assessed efficacy and safety in 221 pts (200 mg [n=117] vs 50 mg [n=104]; data cut-off, Feb 28, 2023): aged ≥75 yrs, 26% (200 mg) vs 16% (50 mg); non-White race, both 29%; high-risk cytogenetics, 36% vs 24%; extramedullary plasmacytomas, both 14%; bone marrow plasma cells ≥50%, 22% vs 35%; median soluble BCMA, both 377 ng/mL. The majority of pts (74% [200 mg] vs 88% [50 mg]) were ≥triple class refractory. Median duration of follow-up was 5.6 mo (200 mg) and 7.7 mo (50 mg). ORR was greater at 200 mg (71%) than 50 mg (50%). Higher ORRs were also seen with 200 vs 50 mg across prespecified subgroups, including by age (18–65 yrs, ORR: 66% vs 42%; ≥65–75 yrs, 79% vs 56%; ≥75 yrs, 68% vs 59%), race (White, 73% vs 45%; non-White, 65% vs 64%), disease stage (ISS stage I, 73% vs 53%; stage II, 73% vs 63%; stage III, 59% vs 25%), functional status (ECOG PS 0, 67% vs 51%; PS 1, 73% vs 50%), serum M protein (< 1.06 g/dL, 84% vs 58%; ≥1.06 g/dL, 57% vs 47%), involved free light chain (< 536 mg/L, 83% vs 55%; ≥536 mg/L, 54% vs 45%), and refractory (refr) status (triple-refr, 68% vs 50%; quad-refr, 77% vs 52%; penta-refr, 61% vs 48%). Median PFS was 7.9 mo at 50 mg and not reached at 200 mg. Dose was escalated from 50 to 200 mg in 8 pts; 75% achieved a VGPR. Treatment-emergent AEs (TEAEs) occurred in all pts (Grade [Gr] ≥3: 79%) at 200 mg and 98% (Gr ≥3: 79%) at 50 mg. Overall, the TEAE profile was similar in both cohorts. The most common TEAE for both doses was cytokine release syndrome (200 mg: 45% [Gr 3: 1%] vs 50 mg: 55% [Gr 3: 2%]); other common TEAEs (>30%) were cough (33% vs 32%), neutropenia (32% vs 28%), fatigue (32% vs 29%), diarrhea (32% vs 28%), anemia (27% vs 40%), and arthralgia (26% vs 31%). There were more opportunistic infections at 200 mg (8% vs 2%). **Conclusions:** Linvoseltamab 200 mg showed higher efficacy than 50 mg. Notably, high ORRs with 200 mg were seen across subgroups, even in high-risk and high tumor burden subgroups. Supporting the higher dose, some pts who progressed on 50 mg responded after dose escalating to 200 mg. With a similar safety profile across both doses, these data indicate 200 mg as the recommended dose for future studies.

Introduction: Trial in progress. Treatment (tx) advancements in recent decades have improved outcomes for patients (pts) with multiple myeloma (MM). However, a subset of pts with high-risk (HR) MM continues to have poor outcomes due to a range of pt- and disease-based factors, with median overall survival (OS) < 24 months. Pts with HRMM have poorly defined treatment options and are often underrepresented in clinical trials; those who fail to achieve MRD negativity after frontline therapy have a particularly high unmet medical need. This phase 2, open-label, multicenter, nonrandomized, pilot study aims to investigate a novel, individualized approach to tx, evaluating the efficacy and safety of teclistamab (tec) + daratumumab (dara) and talquetamab (tal) + dara in pts with HR newly diagnosed (ND) MM, with an early rescue intervention (ERI) guided by MRD assessment. **Methods:** Eligible pts are aged ≥18 years with NDMM per International Myeloma Working Group diagnostic criteria, are eligible for transplant and aged ≤70 years, or are fit pts ineligible for transplant with an Eastern Cooperative Oncology Group performance status of 0 or 1. Pts will have ≥1 of the following HRMM features: adverse cytogenic abnormalities (del[17p], t[4;14], t[14;16], or 1q amplifications detected by fluorescence in situ hybridization), Revised International Staging System (R-ISS) stage 3, and presence of extramedullary disease (EMD). 50% of pts will be ultra-high risk: R-ISS stage 3 or "double hit" (≥2 HR cytogenic abnormalities) or 1 HR cytogenic abnormality and EMD. Induction therapy will consist of dara, bortezomib, lenalidomide, and dexamethasone (D-VRd) and response evaluation, including MRD assessment by multiple techniques. All pts will then receive tec + dara (intensification phase). Following subsequent MRD assessment, pts will be stratified by MRD status. MRD-negative pts will receive tec + dara (maintenance therapy) for a pre-defined period of time. MRD-positive pts will receive tal + dara (ERI) before reassessment. Pts who convert to MRD-negative status will receive tal + dara for a pre-defined period of time; MRD-positive

Introduction: Linvoseltamab is a BCMA×CD3 bispecific antibody (Ab) that has shown promising efficacy and generally manageable safety in patients (pts) with relapsed/refractory multiple myeloma (MM) (Lee et al. Median PFS was 7.9 mo at 50 mg and not reached at 200 mg. Dose was escalated from 50 to 200 mg in 8 pts; 75% achieved a VGPR. Treatment-emergent AEs (TEAEs) occurred in all pts (Grade [Gr] ≥3: 79%) at 200 mg and 98% (Gr ≥3: 79%) at 50 mg. Overall, the TEAE profile was similar in both cohorts. The most common TEAE for both doses was cytokine release syndrome (200 mg: 45% [Gr 3: 1%] vs 50 mg: 55% [Gr 3: 2%]); other common TEAEs (>30%) were cough (33% vs 32%), neutropenia (32% vs 28%), fatigue (32% vs 29%), diarrhea (32% vs 28%), anemia (27% vs 40%), and arthralgia (26% vs 31%). There were more opportunistic infections at 200 mg (8% vs 2%). **Conclusions:** Linvoseltamab 200 mg showed higher efficacy than 50 mg. Notably, high ORRs with 200 mg were seen across subgroups, even in high-risk and high tumor burden subgroups. Supporting the higher dose, some pts who progressed on 50 mg responded after dose escalating to 200 mg. With a similar safety profile across both doses, these data indicate 200 mg as the recommended dose for future studies.

Introduction: Trial in progress. Treatment (tx) advancements in recent decades have improved outcomes for patients (pts) with multiple myeloma (MM). However, a subset of pts with high-risk (HR) MM continues to have poor outcomes due to a range of pt- and disease-based factors, with median overall survival (OS) < 24 months. Pts with HRMM have poorly defined treatment options and are often underrepresented in clinical trials; those who fail to achieve MRD negativity after frontline therapy have a particularly high unmet medical need. This phase 2, open-label, multicenter, nonrandomized, pilot study aims to investigate a novel, individualized approach to tx, evaluating the efficacy and safety of teclistamab (tec) + daratumumab (dara) and talquetamab (tal) + dara in pts with HR newly diagnosed (ND) MM, with an early rescue intervention (ERI) guided by MRD assessment. **Methods:** Eligible pts are aged ≥18 years with NDMM per International Myeloma Working Group diagnostic criteria, are eligible for transplant and aged ≤70 years, or are fit pts ineligible for transplant with an Eastern Cooperative Oncology Group performance status of 0 or 1. Pts will have ≥1 of the following HRMM features: adverse cytogenic abnormalities (del[17p], t[4;14], t[14;16], or 1q amplifications detected by fluorescence in situ hybridization), Revised International Staging System (R-ISS) stage 3, and presence of extramedullary disease (EMD). 50% of pts will be ultra-high risk: R-ISS stage 3 or "double hit" (≥2 HR cytogenic abnormalities) or 1 HR cytogenic abnormality and EMD. Induction therapy will consist of dara, bortezomib, lenalidomide, and dexamethasone (D-VRd) and response evaluation, including MRD assessment by multiple techniques. All pts will then receive tec + dara (intensification phase). Following subsequent MRD assessment, pts will be stratified by MRD status. MRD-negative pts will receive tec + dara (maintenance therapy) for a pre-defined period of time. MRD-positive pts will receive tal + dara (ERI) before reassessment. Pts who convert to MRD-negative status will receive tal + dara for a pre-defined period of time; MRD-positive

pts will receive salvage therapy. If MRD-negative pts convert to MRD-positive status, they will be treated as MRD-positive pts. The primary endpoint is MRD-complete response rate after tx with tec + dara (intensification). Secondary endpoints include percentage of pts who convert to MRD negativity after ERI; percentage of pts with sustained MRD negativity at pre-defined time points in both tx arms; OS; progression-free survival; event-free survival; time to next tx; duration of response; and safety. Exploratory endpoints are immune profiling and genetic characterization. **Results:** Enrollment is expected to begin in May 2023 (target recruitment N=30). **Conclusions:** This study will provide needed data on the effect of MRD-guided individualized tx approaches in management of pts with HRMM, an underrepresented population with a high unmet need.

Trial in progress: linvoseltamab, a BCMAxCD3 bispecific antibody, in a Phase 1b multi-cohort study of combination regimens for patients with relapsed/refractory multiple myeloma

Paula Rodríguez-Otero[1], Nisha Joseph[2], Shaji Kumar[3], Xavier Leleu[4], Salomon Manier[5], Meletios Dimopoulos[6], María-Victoria Mateos[7], Albert Oriol[8], Naresh Bumma[9], Weiying Gong[10], Pourab Roy[11], Karen Rodriguez Lorenc[10], Glenn Kroog[10], Shawn Sarkaria[10]

[1]Clínica Universidad de Navarra, CIMA, CIBERONC, IDISNA, Pamplona, Spain; [2]Winship Cancer Institute at Emory University, Atlanta, GA, USA; [3]Mayo Clinic, Rochester, MN, US; [4]Hospital La Mileterie, Poitiers, France; [5]Centre Hospitalier Universitaire de Lille, Université de Lille, Lille, France; [6]National and Kapodistrian University of Athens; [7]University Hospital of Salamanca/IBSAL/CIC/CIBERONC, Salamanca, Spain; [8]Catalan Institute of Oncology and Josep Carreras Institute, Hospital Germans Trias i Pujol, Badalona, Spain; [9]The Ohio State University Comprehensive Cancer Center, Columbus, OH, USA; [10]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA; [11]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA (at time of study)

Introduction: Trial in Progress. Despite the increased effectiveness of combination drug therapy, multiple myeloma (MM) remains incurable, and patients eventually succumb to relapsed disease. Therefore, new combination regimens are needed to improve outcomes in MM. Linvoseltamab is a bispecific antibody capable of binding to B-cell maturation antigen (BCMA) on MM cells and CD3 on T cells, inducing targeted T-cell-mediated cytotoxicity of MM cells. Results from a Phase 1/2 first-in-human study of linvoseltamab monotherapy in relapsed/refractory MM (RRMM) showed early, deep, and durable responses with manageable safety and tolerability (NCT03761108; Bumma N, et al. Blood. 2022;140(Suppl 1):10140–1). Given these findings, it is reasonable to explore whether combining linvoseltamab with other drugs can improve the depth and duration of responses. **Methods:** LINKER-MM2 (NCT05137054) is a global, Phase 1b, open-label, multi-cohort study designed to assess the safety, tolerability, and efficacy of linvoseltamab in combination with nine different agents (daratumumab, carfilzomib, lenalidomide, bortezomib, pomalidomide, isatuximab, fianlimab, cemiplimab, or nirogacestat) in separate cohorts of participants with RRMM. Prior exposure to a combination agent is allowed if previously tolerated at the full dose (after a minimum washout period), although some cohorts exclude patients with disease refractory to the cohort-specific combination treatment. The study includes a dose-finding portion to select an appropriate linvoseltamab dose, followed by a dose-expansion portion for each cohort. Linvoseltamab is administered intravenously starting on a weekly basis from initiation of the step-up schedule through the first 15-16 weeks and then transition to every 2-3 weeks. All regimens are given until disease progression or any other reason for discontinuation. Estimated total enrollment is ~315 participants. Eligible patients are 18 years or older with RRMM that progressed after ≥3 lines of therapy, have an Eastern Cooperative Oncology Group performance status ≤1, and have adequate organ function. Key exclusion criteria include the presence of MM brain lesions or meningeal involvement, and previous treatment with certain BCMA-directed therapies depending on the cohort. The primary endpoint is safety and tolerability of each linvoseltamab combination, in terms of dose-limiting toxicities (dose-finding portion only) and treatment-emergent adverse events. Secondary endpoints are objective response rate, duration of response, progression-free survival, minimal residual disease status, pharmacokinetics, immunogenicity, and overall survival. This study is actively recruiting participants and anticipated to open at 50 global sites. **Conclusions:** Analyses from the LINKER-MM2 study will provide important information on the tolerability and preliminary clinical efficacy of linvoseltamab when given in combination with other cancer therapies, aiming to improve care for patients with RRMM.

Introduction: IGM-2644 is an engineered high-affinity, high-avidity bispecific anti-CD38 IgM antibody T cell engager (TCE) being developed for the treatment of RRMM. CD38 is a uniformly highly expressed cell surface glycoprotein on neoplastic plasma cells. IGM-2644 is designed to selectively target and kill myeloma cells through both T-cell dependent cellular toxicity (TDCC) and complement dependent cytotoxicity (CDC). In preclinical models, IGM-2644 demonstrates superior CDC and cellular-dependent cytotoxicity compared to daratumumab, especially on low CD38-expressing tumor cells. IGM-2644 may have an improved safety profile compared to bispecific IgGs due to lower cytokine release and

pts will receive salvage therapy. If MRD-negative pts convert to MRD-positive status, they will be treated as MRD-positive pts. The primary endpoint is MRD-complete response rate after tx with tec + dara (intensification). Secondary endpoints include percentage of pts who convert to MRD negativity after ERI; percentage of pts with sustained MRD negativity at pre-defined time points in both tx arms; OS; progression-free survival; event-free survival; time to next tx; duration of response; and safety. Exploratory endpoints are immune profiling and genetic characterization. **Results:** Enrollment is expected to begin in May 2023 (target recruitment N=30). **Conclusions:** This study will provide needed data on the effect of MRD-guided individualized tx approaches in management of pts with HRMM, an underrepresented population with a high unmet need.

Introduction: IGM-2644 is an engineered high-affinity, high-avidity bispecific anti-CD38 IgM antibody T cell engager (TCE) being developed for the treatment of RRMM. CD38 is a uniformly highly expressed cell surface glycoprotein on neoplastic plasma cells. IGM-2644 is designed to selectively target and kill myeloma cells through both T-cell dependent cellular toxicity (TDCC) and complement dependent cytotoxicity (CDC). In preclinical models, IGM-2644 demonstrates superior CDC and cellular-dependent cytotoxicity compared to daratumumab, especially on low CD38-expressing tumor cells. IGM-2644 may have an improved safety profile compared to bispecific IgGs due to lower cytokine release and

reduced immune cell fratricide with comparable anti-tumor activity in ex vivo and in vivo MM models. **Methods:** This is a first-in-human, Phase 1, multicenter, open-label study to determine the safety and tolerability of IGM-2644 as a single agent in participants (N=30-60) with RRMM. Expansion cohorts will be enrolled to evaluate preliminary efficacy and further define a recommended Phase 2 dose (RP2D). A step-up dosing regimen will be used, with successively higher doses of IGM-2644 administered during a priming cycle. The optimal number and magnitude of steps to reach the plateau RP2D will be determined progressively. At the start of dose escalation, the same dose level will be administered on all dosing days during the priming cycle until a Dose 1 is fixed. Doses 2 and 3 will then be increased in parallel until a Dose 2 maximum tolerated dose (MTD) is defined. The Safety Review Committee may recommend fixing Dose 2 at or below the MTD and continuing escalation of the third priming dose. The highest dose achieved during the priming cycle will represent the plateau dose to be administered once per week in 3-week cycles. Pharmacokinetics, pharmacodynamics, efficacy, and safety data collected throughout the treatment period may be used to support potentially less frequent dosing. A single participant will initially be enrolled into each dose-escalation cohort. Conversion to a standard 3+3 escalation format will be based on the occurrence of one of specified safety events or the achievement of a predetermined dose level, whichever occurs first. Correlative biomarker studies include assessment of blood and tissue biomarkers for association with clinical benefit. **Conclusions:** IGM-2644 is a novel bispecific IgM T cell engager with both CDC and TDCC mechanisms of cytotoxicity and the potential to be active in daratumumab-resistant tumors. This Phase 1 trial is underway, and results will be presented at a future meeting.

Point-of-care anti-BCMA CAR T-cell therapy induces encouraging response rates in relapsed/refractory multiple myeloma patients mostly with high-risk disease features

Eden Shkury[1], Shalev Fried[1], Orit Itzhaki[1], Noga Shem-Tov[1], Ivetta Danylesko[1], Ronit Yerushalmi[1], Roni Shouval[2], Lee Nevo[1], Ronnie Shapira-Frommer[1], Arnon Nagler[1], Avichai Shimoni[1], Abraham Avigdor[1], Hila Magen[1]

[1]Chaim Sheba Medical Center; [2]Memorial Sloan Kettering

Introduction: Anti-BCMA chimeric antigen receptor (CAR) T-cell therapy showed excellent efficacy in relapsed/refractory multiple myeloma (R/R MM) patients (pts). Point-of-care (POC) CAR manufacturing abrogates the need for cryopreservation and shipment of cells, thus shortening the manufacturing process and reducing the necessity of bridging therapy. We report outcomes of phase 1b/2 single center clinical trial of autologous POC anti-BCMA CAR T-cell therapy in pts with R/R MM treated with ≥ 3 prior therapies. **Methods:** Pts underwent a single peripheral blood leukapheresis. Fresh T-cells were transduced with retroviral vector encoding the anti-BCMA CAR (based on 11D5-3 ScFv, CD28 costimulatory domain and CD3-ζ signaling domain). Cell dose was 6×10^6/kg (dose level I [n=3]) or 9×10^6/kg (dose level II [n=33]). Primary endpoints were overall response rate (ORR) per IMWG criteria and safety. Secondary endpoints were overall survival (OS) and progression-free survival (PFS). Last follow-up was 05/2023. **Results:** Since 11/2021, 36 pts enrolled (median age 60, IQR 54-67). All pts received CAR T-cell infusion in a median of 11 days (IQR 11-14) after leukapheresis. Only 2 pts received bridging therapy. The median number of prior therapies was 4 (IQR 3-5), with 61% and 33% of the pts being penta and quad-refractory, respectively. 7 (19%) pts had prior exposure to BCMA-targeted therapy (belantamab mafodotin, n=5 [14%]; talqeutamab, n=2 [6%]). At enrollment, 12 (33%) pts had high-risk cytogenetics, 9 (25%) had double-hit myeloma, and 18 (50%) had extramedullary involvement. Only 19 (53%) and 18 (50%) pts were eligible to enroll in the KarMMa (NEJM, 2021) and CARTITUDE-1 (Lancet, 2021) studies, respectively. Only 1 patient (3%) developed grade ≥ 3 cytokine release syndrome, and 1 patient (3%) developed grade ≥ 3 immune effector cell-associated neurotoxicity syndrome. Grade 3-4 neutropenia and thrombocytopenia occurred in 35 (97%) and 19 (53%) pts, respectively. Anemia requiring transfusion occurred in 17 (47%) pts. No grade 3-4 adverse events nor cellular therapy-related deaths were observed. The median follow-up was 6.4 months (IQR 4.9-10.7). Best ORR (PR at least) was 64% (VGPR at least, 50%). Median time to first response was 31 days (95% CI: 26-33). Estimated 6-months OS, PFS and duration of response were 87% (95% CI: 76-100), 46% (95% CI: 31-67), and 61% (95% CI: 41-89), respectively. Pts with prior exposure to BCMA-targeted therapies had an inferior PFS (HR 2.9 [95% CI: 1.1-7.8] p=0.04). **Conclusions:** POC anti-BCMA CAR T-cells induced high response rates with an excellent safety profile in R/R MM pts mostly not eligible to be enrolled in the pivotal trials. The rapid CAR-T production time obviated the need for bridging therapy in most pts. It is noteworthy that prior exposure to BCMA-targeted therapies is associated with dismal PFS, hence those therapies should be carefully considered when CAR T-cell therapy might be intended.

Conversion to a standard 3+3 escalation format will be based on the occurrence of one of specified safety events or the achievement of a predetermined dose level, whichever occurs first. Correlative biomarker studies include assessment of blood and tissue biomarkers for association with clinical benefit. **Conclusions:** IGM-2644 is a novel bispecific IgM T cell engager with both CDC and TDCC mechanisms of cytotoxicity and the potential to be active in daratumumab-resistant tumors. This Phase 1 trial is underway, and results will be presented at a future meeting.

Point-of-care anti-BCMA CAR T-cell therapy induces encouraging response rates in relapsed/refractory multiple myeloma patients mostly with high-risk disease features

Eden Shkury[1], Shalev Fried[1], Orit Itzhaki[1], Noga Shem-Tov[1], Ivetta Danylesko[1], Ronit Yerushalmi[1], Roni Shouval[2], Lee Nevo[1], Ronnie Shapira-Frommer[1], Arnon Nagler[1], Avichai Shimoni[1], Abraham Avigdor[1], Hila Magen[1]

[1]Chaim Sheba Medical Center; [2]Memorial Sloan Kettering

Introduction: Anti-BCMA chimeric antigen receptor (CAR) T-cell therapy showed excellent efficacy in relapsed/refractory multiple myeloma (R/R MM) patients (pts). Point-of-care (POC) CAR manufacturing abrogates the need for cryopreservation and shipment of cells, thus shortening the manufacturing process and reducing the necessity of bridging therapy. We report outcomes of phase 1b/2 single center clinical trial of autologous POC anti-BCMA CAR T-cell therapy in pts with R/R MM treated with ≥ 3 prior therapies. **Methods:** Pts underwent a single peripheral blood leukapheresis. Fresh T-cells were transduced with retroviral vector encoding the anti-BCMA CAR (based on 11D5-3 ScFv, CD28 costimulatory domain and CD3-ζ signaling domain). Cell dose was 6×10^6/kg (dose level I [n=3]) or 9×10^6/kg (dose level II [n=33]). Primary endpoints were overall response rate (ORR) per IMWG criteria and safety. Secondary endpoints were overall survival (OS) and progression-free survival (PFS). Last follow-up was 05/2023. **Results:** Since 11/2021, 36 pts enrolled (median age 60, IQR 54-67). All pts received CAR T-cell infusion in a median of 11 days (IQR 11-14) after leukapheresis. Only 2 pts received bridging therapy. The median number of prior therapies was 4 (IQR 3-5), with 61% and 33% of the pts being penta and quad-refractory, respectively. 7 (19%) pts had prior exposure to BCMA-targeted therapy (belantamab mafodotin, n=5 [14%]; talqeutamab, n=2 [6%]). At enrollment, 12 (33%) pts had high-risk cytogenetics, 9 (25%) had double-hit myeloma, and 18 (50%) had extramedullary involvement. Only 19 (53%) and 18 (50%) pts were eligible to enroll in the KarMMa (NEJM, 2021) and CARTITUDE-1 (Lancet, 2021) studies, respectively. Only 1 patient (3%) developed grade ≥ 3 cytokine release syndrome, and 1 patient (3%) developed grade ≥ 3 immune effector cell-associated neurotoxicity syndrome. Grade 3-4 neutropenia and thrombocytopenia occurred in 35 (97%) and 19 (53%) pts, respectively. Anemia requiring transfusion occurred in 17 (47%) pts. No grade 3-4 adverse events nor cellular therapy-related deaths were observed. The median follow-up was 6.4 months (IQR 4.9-10.7). Best ORR (PR at least) was 64% (VGPR at least, 50%). Median time to first response was 31 days (95% CI: 26-33). Estimated 6-months OS, PFS and duration of response were 87% (95% CI: 76-100), 46% (95% CI: 31-67), and 61% (95% CI: 41-89), respectively. Pts with prior exposure to BCMA-targeted therapies had an inferior PFS (HR 2.9 [95% CI: 1.1-7.8] p=0.04). **Conclusions:** POC anti-BCMA CAR T-cells induced high response rates with an excellent safety profile in R/R MM pts mostly not eligible to be enrolled in the pivotal trials. The rapid CAR-T production time obviated the need for bridging therapy in most pts. It is noteworthy that prior exposure to BCMA-targeted therapies is associated with dismal PFS, hence those therapies should be carefully considered when CAR T-cell therapy might be intended.

Safety and efficacy of standard of care ciltacabtagene autoleucel (Cilta-cel) for relapsed/refractory multiple myeloma (RRMM): real world experience

Surbhi Sidana[1,], Krina Patel[2,*], Lauren Peres[3], Radhika Bansal[4], M Hakan Kocoglu[5], Leyla Shune[6], Shebli Atrash[7], Kinaya Smith[8], Christopher Ferreri[2], Binod Dhakal[8], Saurabh Chhabra[4], Ricardo Parrondo[4], Patrick Costello[9], Shonali Midha[9], Thomas Martin[10], Gary Simmons[11], Melissa Alsina[3], Myo Htut[12], Peter Voorhees[13], Douglas Sborov[14], Jack Khouri[15], Sandy Wong[10], Murali Janakiram[12,*], Yi Lin[4,*], Doris Hansen[3,*]*

[1]Stanford University; [2]MD Anderson Cancer Center, University of Texas, Houston, TX, USA; [3]Moffiitt Cancer Center; [4]Mayo Clinic; [5]University of Maryland, Baltimore, MD, USA; [6]University of Kansas Medical Center; [7]Levine Cancer Institute; [8]Medical College of Wisconsin; [9]Dana Farber Cancer Institute; [10]University of California,

reduced immune cell fratricide with comparable anti-tumor activity in ex vivo and in vivo MM models. **Methods:** This is a first-in-human, Phase 1, multicenter, open-label study to determine the safety and tolerability of IGM-2644 as a single agent in participants (N=30-60) with RRMM. Expansion cohorts will be enrolled to evaluate preliminary efficacy and further define a recommended Phase 2 dose (RP2D). A step-up dosing regimen will be used, with successively higher doses of IGM-2644 administered during a priming cycle. The optimal number and magnitude of steps to reach the plateau RP2D will be determined progressively. At the start of dose escalation, the same dose level will be administered on all dosing days during the priming cycle until a Dose 1 is fixed. Doses 2 and 3 will then be increased in parallel until a Dose 2 maximum tolerated dose (MTD) is defined. The Safety Review Committee may recommend fixing Dose 2 at or below the MTD and continuing escalation of the third priming dose. The highest dose achieved during the priming cycle will represent the plateau dose to be administered once per week in 3-week cycles. Pharmacokinetics, pharmacodynamics, efficacy, and safety data collected throughout the treatment period may be used to support potentially less frequent dosing. A single participant will initially be enrolled into each dose-escalation cohort. Conversion to a standard 3+3 escalation format will be based on the occurrence of one of specified safety events or the achievement of a predetermined dose level, whichever occurs first. Correlative biomarker studies include assessment of blood and tissue biomarkers for association with clinical benefit. **Conclusions:** IGM-2644 is a novel bispecific IgM T cell engager with both CDC and TDCC mechanisms of cytotoxicity and the potential to be active in daratumumab-resistant tumors. This Phase 1 trial is underway, and results will be presented at a future meeting.

San Francisco, San Francisco, CA, USA; [11]Virgina Commonwealth University; [12]City of Hope Comprehensive Cancer Center; [13]Levine Cancer Institute-Atrium Health Wake Forest University School of Medicine; [14]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, USA; [15]Taussig Cancer Institute, Cleveland Clinic; *SS, KP, MJ, YL and DH contributed equally

Introduction: In this multi-center study, we evaluated the outcomes of patients treated with intended standard of care cilta-cel. **Methods:** Patients at 14 US academic centers who underwent apheresis with intention to manufacture cilta-cel by 9/15/2022 were included. Data cut-off was April 1, 2023. **Results:** 153 patients underwent apheresis and 143 (94%) received cilta-cel infusion. 10 patients did not get cilta-cel due to progression/death (6), myelodysplastic syndrome (1), manufacturing failure (1), OOS product declined by patient (1) and lost to follow up (1). Amongst patients receiving cilta-cel (N=143), median age was 64 years, with 27% being above age 70; 57% were male, 34% had penta-refractory disease. Compared to CARTITUDE-1 study population, our cohort had higher incidence of extramedullary disease (EMD, 31% vs 13%) and high-risk cytogenetics (41% vs 24%). 57% of the patients would not have met eligibility criteria for CARTITUDE-1. Common reasons for ineligibility were cytopenias (17%), prior BCMA therapy (15%), organ dysfunction (12%), poor performance status (11%) and plasma cell leukemia (7%). 80% of the patients received bridging chemotherapy (overall response rate, ORR: 30%). Lymphodepletion included fludarabine (Flu) + cyclophosphamide (Cy): 84%, bendamustine: 9%, Cy: 3.5%, and cladribine + Cy: 3.5%. Median CAR-T cells infused were 0.6 million/kg, and 22% of patients were treated on expanded access protocol (EAP). Median follow-up was 6 months. Cytokine release syndrome (CRS) was seen in 80% (≥ grade 3: 5%), immune effector cell-associated neurotoxicity syndrome (ICANS) in 18% (≥ grade 3: 6%) and hemophagocytic lymphohistiocytosis (HLH)-like syndrome in 3% of patients. Tocilizumab, steroids, and anakinra were used in 61%, 41%, and 13% of patients, respectively. Delayed neurotoxicity (NT) was seen in 12% (n=17; 7th cranial nerve palsy: 9, Parkinsonism: 2, others: 6), with median time to onset being 25 days. It resolved in 6 patients by last follow-up, while 3 patients died with ongoing delayed NT. Infections were seen in 37% of patients. Day 30 (N=134) and best response rates (N=140) were: ≥ partial response (PR), 81/89%; ≥ very good PR, 51/77%; and ≥ complete response (CR), 29/56%, respectively. In the non-EAP FluCy population (N=92), ORR/≥CR were 94/61%. Median progression free survival was not reached, with 6-month estimate being 79%. 22 patients died by data cut-off, including 14 (10%) due to non-relapse mortality (infection:6, grade 5 CRS:3, CRS/infection:1 grade 5 ICANS:1, delayed NT:2, HLH:1). **Conclusions:** Patients treated with SOC cilta-cel had a favorable ORR (89%) and CR rate (56%) despite a larger proportion of patients having high-risk features relative to trial patients. Response rates were higher in patients receiving conforming products with FluCy conditioning (94%). Delayed NT was seen in 12% and non-relapse mortality in 10% of patients, respectively.

GEN3014 (HexaBody®-CD38) versus daratumumab in patients with relapsed/refractory multiple myeloma: design of randomized head-to-head expansion cohort of phase 1/2 trial

Sebastian Grosicki[1], Binod Dhakal[2], Ehsan Malek[3], Maria Creignou[4], Wojciech Jurczak[5], Annemiek Broijl[6], Katrine Fladeland Iversen[7], Henrik Gregersen[8], Jakub Radocha[9], Jenny Chen[10], Adeleye Ogunkanmi[10], Andrew Spencer[11]

[1]Dept. of Hematology and Cancer Prevention, Medical University of Silesia, Katowice, Poland; [2]Medical College of Wisconsin, Milwaukee, WI, USA; [3]University Hospitals Cleveland Medical Center, Cleveland, OH, USA; [4]Karolinska University Hospital, Stockholm, Sweden; [5]MSC National Research Institute of Oncology, Kraków, Poland; [6]Erasmus MC Cancer Institute, Rotterdam, Netherlands; [7]Vejle Hospital, Vejle, Denmark; [8]Aalborg University Hospital, Aalborg, Denmark; [9]4th Department of Internal Medicine – Hematology, University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic; [10]Genmab, Princeton, NJ, USA; [11]Alfred Health-Monash University, Melbourne, VIC, Australia

Introduction: The approval of CD38-targeted antibodies, such as daratumumab, has changed the treatment landscape for relapsed/refractory multiple myeloma (RRMM). Despite this advancement, patients still progress following daratumumab treatment; therefore, more potent treatment options with higher affinity for CD38 may improve clinical outcomes. GEN3014 (HexaBody®-CD38) is a novel human IgG1 anti-CD38 monoclonal antibody (mAb) that contains the hexamerization enhancing mutation E430G, which facilitates highly efficient complement-dependent cytotoxicity (CDC). In preclinical studies, GEN3014 showed highly potent tumor-cell killing through CDC and was more potent than daratumumab (Hiemstra et al, EHA 2020). Potent antibody dependent cellular cytotoxicity and cellular phagocytosis activity were demonstrated. Preliminary results from the dose-escalation portion of the first-in-human phase 1/2 trial of GEN3014 in patients with RRMM showed a tolerable safety profile and clinical activity, and the recommended phase 2 dose was determined to be 16 mg/kg. Based on these results, the study proceeded with expansion cohorts. Following an interim analysis of 10 anti-CD38 mAb–naive patients with RRMM who had received 16 or 24 mg/kg GEN3014 in the dose-escalation or initial expansion cohorts, an additional 80 anti-CD38 mAb–naive patients with RRMM are to be randomized 1:1 to receive either GEN3014 or daratumumab. Herein we describe the design of the randomized, head-to-head expansion cohort. **Methods:** This is a phase 1/2 open-label, multicenter, multinational trial (NCT04824794) designed to evaluate the safety, tolerability, pharmacokinetics/pharmacodynamics, immunogenicity, and preliminary efficacy of GEN3014 treatment in patients with RRMM or other hematologic malignancies. Patients in the randomized, head-to-head expansion cohort must have documented RRMM based on IMWG criteria and ≥3 prior lines of treatment (including a protease inhibitor [PI] and an immunomodulatory imide drug [IMiD]) or ≥2 prior lines of treatment (including a combination of a PI and an IMiD). Patients

Herein we describe the design of the randomized, head-to-head expansion cohort. **Methods:** This is a phase 1/2 open-label, multicenter, multinational trial (NCT04824794) designed to evaluate the safety, tolerability, pharmacokinetics/pharmacodynamics, immunogenicity, and preliminary efficacy of GEN3014 treatment in patients with RRMM or other hematologic malignancies. Patients in the randomized, head-to-head expansion cohort must have documented RRMM based on IMWG criteria and ≥3 prior lines of treatment (including a protease inhibitor [PI] and an immunomodulatory imide drug [IMiD]) or ≥2 prior lines of treatment (including a combination of a PI and an IMiD). Patients

will receive either GEN3014 16 mg/kg IV or daratumumab 1800 mg subcutaneously in 28-d cycles (C) as follows: QW, C1–2; Q2W, C3–6; Q4W, C≥7 until disease progression or unacceptable toxicity. The primary endpoint of this randomized expansion cohort is objective response rate. Secondary efficacy endpoints include very good partial response or better rate, complete response or better rate, duration of response, time to response, progression free survival, overall survival, and time to next therapy. Patient enrollment is ongoing. Anti-CD38 mAb–naive patients with RRMM will be enrolled from countries outside the United States.

Safety and efficacy of chimeric antigen receptor T cell therapy in patients with relapse or refractory multiple myeloma and hepatitis B virus-infection

Ying Wang[1], Feng Zhu[1], Jiang Cao[2], Kunming Qi[1], Zhiling Yan[2], Hai Cheng[1], Wei Sang[1], Depeng Li[1], Zhenyu Li[2], Kailin Xu[2]

[1]Xuzhou Medical University; [2]Blood Diseases Institute, Xuzhou Medical University

Introduction: Chimeric antigen receptor (CAR) T-cell therapy has shown encouraging results in patients with relapse or refractory multiple myeloma (RRMM). However, there are certain percentages of patients with RRMM and concomitant hepatitis B virus (HBV) infection, which remains confusion in clinical application of CAR-T cells. This study aimed to explore the safety and efficacy of patients with RRMM and concomitant HBV infection after anti-BCMA and/or anti-CD19 CAR-T cell therapy. **Methods:** Patients with RRMM and concomitant chronic or resolved HBV infection receiving anti-BCMA and/or anti-CD19 CAR T-cell therapy were enrolled. Patients without HBV infection were choosed as control. Clinical and laboratory datda were collected. The occurrence of HBV reactivation was analyzed among the 3 cohorts. The incidence and severity of liver injury and CRS were compared, as were the efficacy and long-term outcomes. The possible role and mechanism of immune status on HBV reactivation were explored by analyzing the changes of lymphocyte subsets among the 3 cohorts. **Results:** Among the 5 patients with chronic HBV infection and 12 patients with resolved HBV infection, only 1 patient with resolved HBV infection experienced HBV reactivation after CAR T-cell infusion, while no patient in no HBV infection cohort developing new HBV-infection. There was no HBV-related hepatitis flare. The incidence of alanine aminotransferase elevation (> 80U/L) was 20% (1/5), 25% (3/12) and 35.71% (5/14) in chronic, resolved, and no HBV infection cohorts, respectively, without statistical difference. After CAR T-cell therapy, the counts of CD4+ and CD8+ lymphocytes decreased, CD4/CD8 inverted. CD19+ lymphocytes decreased significantly and remained depressed up to 2 months post-infusion without difference among the 3 cohorts. The ORRs of patients in the three cohorts after CAR T-cell infusion were 100% (5/5), 91.67 (11/12), 100% (14/14), and the median PFS were 384, 349, and 581 days, respectively, without significant difference. The incidence of CRS in the three cohorts were 80%, 91.67% and 100%, respectively, and there was no significant difference in the incidence and severity of CRS among the three cohorts. **Conclusions:** CAR-T cell therapy could be used in patients with RRMM and concomitant chronic or resolved HBV-infection. HBV serological markers, HBV-DNA, and liver enzymes be closely monitored in these patients during CAR-T cell therapy.

Introduction: Trial in Progress. Frontline treatment for multiple myeloma (MM) often utilizes combinations of 2–4 classes of active drugs, including an immunomodulatory drug, a proteasome inhibitor (PI), and an anti-CD38 mAb. However, relapse is a persistent problem and there is no single treatment algorithm for RRMM. Pomalidomide-based regimens are available for RRMM, with those that avoid reuse of anti-CD38 mAbs assuming greater importance following the positioning of these mAbs in frontline therapy. EPd is a recognized anti-CD38 mAb-free combination, although only ~50% of patients (pts) with RRMM responded to EPd in a pivotal study. The need for drugs that have new mechanisms of action is thus important, particularly for triple-class exposed (TCE) RRMM. Linvoseltamab is a BCMA×CD3 bispecific antibody that induces T-cell-mediated cytotoxicity of BCMA-expressing MM cells. In the Phase 1/2 LINKER-MM1 study, linvoseltamab monotherapy achieved early, deep, and durable responses in pts with TCE RRMM, with a manageable safety profile (Bumma, et al. ASH, 2022). Considering these positive data and the current unmet need, we aim to assess the utility of linvoseltamab monotherapy as a novel alternative treatment relative to a standard pomalidomide-based triplet therapy for pts with RRMM in the LINKER-MM3 study. **Methods:** LINKER-MM3 (NCT05730036) is a Phase 3, open-label, randomized study of linvoseltamab monotherapy vs EPd combination therapy in pts with RRMM. Pts will have received 1–4 prior lines of therapy (2–4 in the EU and UK), including lenalidomide and a PI, and have progressed on/after last therapy. In the EU and UK, pts must also have had prior anti-CD38 mAb

will receive either GEN3014 16 mg/kg IV or daratumumab 1800 mg subcutaneously in 28-d cycles (C) as follows: QW, C1–2; Q2W, C3–6; Q4W, C≥7 until disease progression or unacceptable toxicity. The primary endpoint of this randomized expansion cohort is objective response rate. Secondary efficacy endpoints include very good partial response or better rate, complete response or better rate, duration of response, time to response, progression free survival, overall survival, and time to next therapy. Patient enrollment is ongoing. Anti-CD38 mAb–naive patients with RRMM will be enrolled from countries outside the United States.

Introduction: Chimeric antigen receptor (CAR) T-cell therapy has shown encouraging results in patients with relapse or refractory multiple myeloma (RRMM). However, there are certain percentages of patients with RRMM and concomitant hepatitis B virus (HBV) infection, which remains confusion in clinical application of CAR-T cells. This study aimed to explore the safety and efficacy of patients with RRMM and concomitant HBV infection after anti-BCMA and/or anti-CD19 CAR-T cell therapy. **Methods:** Patients with RRMM and concomitant chronic or resolved HBV infection receiving anti-BCMA and/or anti-CD19 CAR T-cell therapy were enrolled. Patients without HBV infection were choosed as control. Clinical and laboratory datda were collected. The occurrence of HBV reactivation was analyzed among the 3 cohorts. The incidence and severity of liver injury and CRS were compared, as were the efficacy and long-term outcomes. The possible role and mechanism of immune status on HBV reactivation were explored by analyzing the changes of lymphocyte subsets among the 3 cohorts. **Results:** Among the 5 patients with chronic HBV infection and 12 patients with resolved HBV infection, only 1 patient with resolved HBV infection experienced HBV reactivation after CAR T-cell infusion, while no patient in no HBV infection cohort developing new HBV-infection. There was no HBV-related hepatitis flare. The incidence of alanine aminotransferase elevation (> 80U/L) was 20% (1/5), 25% (3/12) and 35.71% (5/14) in chronic, resolved, and no HBV infection cohorts, respectively, without statistical difference. After CAR T-cell therapy, the counts of CD4+ and CD8+ lymphocytes decreased, CD4/CD8 inverted. CD19+ lymphocytes decreased significantly and remained depressed up to 2 months post-infusion without difference among the 3 cohorts. The ORRs of patients in the three cohorts after CAR T-cell infusion were 100% (5/5), 91.67 (11/12), 100% (14/14), and the median PFS were 384, 349, and 581 days, respectively, without significant difference. The incidence of CRS in the three cohorts were 80%, 91.67% and 100%, respectively, and there was no significant difference in the incidence and severity of CRS among the three cohorts. **Conclusions:** CAR-T cell therapy could be used in patients with RRMM and concomitant chronic or resolved HBV-infection. HBV serological markers, HBV-DNA, and liver enzymes be closely monitored in these patients during CAR-T cell therapy.

Introduction: Trial in Progress. Frontline treatment for multiple myeloma (MM) often utilizes combinations of 2–4 classes of active drugs, including an immunomodulatory drug, a proteasome inhibitor (PI), and an anti-CD38 mAb. However, relapse is a persistent problem and there is no single treatment algorithm for RRMM. Pomalidomide-based regimens are available for RRMM, with those that avoid reuse of anti-CD38 mAbs assuming greater importance following the positioning of these mAbs in frontline therapy. EPd is a recognized anti-CD38 mAb-free combination, although only ~50% of patients (pts) with RRMM responded to EPd in a pivotal study. The need for drugs that have new mechanisms of action is thus important, particularly for triple-class exposed (TCE) RRMM. Linvoseltamab is a BCMA×CD3 bispecific antibody that induces T-cell-mediated cytotoxicity of BCMA-expressing MM cells. In the Phase 1/2 LINKER-MM1 study, linvoseltamab monotherapy achieved early, deep, and durable responses in pts with TCE RRMM, with a manageable safety profile (Bumma, et al. ASH, 2022). Considering these positive data and the current unmet need, we aim to assess the utility of linvoseltamab monotherapy as a novel alternative treatment relative to a standard pomalidomide-based triplet therapy for pts with RRMM in the LINKER-MM3 study. **Methods:** LINKER-MM3 (NCT05730036) is a Phase 3, open-label, randomized study of linvoseltamab monotherapy vs EPd combination therapy in pts with RRMM. Pts will have received 1–4 prior lines of therapy (2–4 in the EU and UK), including lenalidomide and a PI, and have progressed on/after last therapy. In the EU and UK, pts must also have had prior anti-CD38 mAb

treatment. Other key eligibility criteria include measurable disease per 2016 IMWG criteria; ≥18 years of age; adequate bone marrow reserves and hepatic, renal, and cardiac function; and no prior treatment with elotuzumab, pomalidomide, or BCMA-directed immunotherapies. Linvoseltamab will be given in 28-day cycles, with step-up dosing to the full dose undertaken during Cycle 1. EPd treatment will also be given in 28-day cycles, according to the package inserts. Both treatment regimens will be given until disease progression or another defined reason for drug discontinuation. The study will take place at ~180 sites globally. A total of ~300 pts will be randomized (1:1) to IV linvoseltamab or EPd, stratified by prior anti-CD38 mAb exposure, International Staging System stage, and extramedullary plasmacytoma status. The primary endpoint is progression-free survival per IMWG criteria, determined by independent review committee (IRC). Key secondary endpoints are objective response rate (including rates of very good partial response or better and complete response or better, determined by IRC); MRD status; overall survival; and change in pain at Week 12 (Brief Pain Inventory-Short Form, Item 3). Incidence/severity of treatment-emergent AEs will also be assessed. Study enrollment is planned to begin in Q3 2023.

Idecabtagene vicleucel (ide-cel) retreatment response was characterized by poor activation, impaired cellular expansion, and limited cytolytic activity of chimeric antigen receptor (CAR) T cells

Fan Wu[1], Ye Shen[1], Xirong Zheng[1], Manisha Lamba[1], Nathan Martin[1], Shari Kaiser[1], Rashmi Bhatnagar[2], Nikhil Munshi[3], Sagar Lonial[4], Yi Lin[5], Jesús San-Miguel[6], Payal Patel[1], Timothy Campbell[1]

[1]Bristol Myers Squibb, Princeton NJ, USA; [2]Syneos Health, Gurugram, Haryana, India; [3]Dana-Farber Cancer Institute, Boston, MA, USA, Veterans Affairs Boston Healthcare System/Harvard Medical School; [4]Winship Cancer Institute, Emory University, Atlanta, GA, USA; [5]Mayo Clinic, Rochester, MN, USA; [6]Cancer Center Clinica Universidad de Navarra, Centro Investigacion Medica Aplicada, Instituto de Investigacion de Navarra, Centro Investigacion Biomedica en Red Cancer, Pamplona, Spain

Introduction: Retreating patients with the same CAR T product has been explored across several CAR T products after progression during initial treatment. Suboptimal efficacy has generally been observed in retreated patients, even if they had achieved favorable responses after their first infusion. We conducted analyses to systematically compare overall response, cellular kinetics, humoral immunogenicity, and pharmacodynamic (PD) responses from initial and retreatment phases for patients retreated with ide-cel. **Methods:** 31/128 patients (25.8%) were retreated with a second dose of ide-cel (12/21/2020 data cutoff) in the KarMMa study (NCT03361748). Peripheral blood cellular kinetics were evaluated by quantitative PCR in CD3-sorted cells. Formulation of humoral immunogenicity to ide-cel were evaluated using an immunoassay in serum samples. Immunophenotype of CAR+ T cells was evaluated by flow cytometry. Soluble BCMA (sBCMA) and proinflammatory cytokines were evaluated by immunoassay. Clinical response was evaluated using IMWG criteria. **Results:** Low ORR (19.4%, 6/31) was observed with retreatment compared with initial treatment (83.9%, 26/31). Progression-free survival (PFS; median [95% CI]) after ide-cel retreatment was 1.0 (1.0–2.0) months, substantially shorter than PFS (7.1 [4.9–10.4] months) after initial ide-cel treatment. Fewer patients retreated with ide-cel experienced cytokine release syndrome (45.2% vs 80.6%) or investigator-identified neurotoxicity (3.2% vs 16%) than those on or after initial treatment. Induction of proinflammatory cytokines, indicating CAR T activation, was dampened during retreatment and minimal PD responses were observed. In 29 patients who received a second dose of ide-cel ranging from 300–450x10^6 CAR+ T cells, median Cmax following retreatment was 5.2-fold lower while median AUC0–28days was 8.6-fold lower than the initial infusion, despite most of the patients (23/29) receiving a higher target dose in the second infusion. CAR T cells expanding after retreatment were characterized by decreased proportions of CD4+ and CD8+ CAR+ subsets for proliferating (Ki67+) and TEM (CCR7–/CD45RA–) cells versus initial infusion. The magnitude of dampened CAR T activation and PD activity in retreatment trended higher in patients (19/31) who were anti-drug antibody (ADA) positive proximal to initiation of retreatment. **Conclusions:** A lower ORR was observed in patients following ide-cel retreatment compared with initial treatment. Ide-cel retreatment was characterized by suboptimal activation and expansion, consistent with the limited efficacy observed. ADA may be implicated in retreatment but does not fully explain the observed CAR T activation dampening that was observed across the entire retreatment cohort. The mechanisms underlying suboptimal ide-cel activation during retreatment remain not fully elucidated and are likely multifactorial and distinct from features characterizing suboptimal response to initial infusion.

Optimizing the Vk*MYC multiple myeloma model to investigate osteolytic bone lesions

Melika Bakharzi[1], Elizabeth Fung[2], Afsaneh Panahi[1,2], Glenn Edin[2], Arefeh Rouhi[1,2], Florian Kuchenbauer[2,3]

[1]University of British Columbia; [2]BC Cancer Research Center; [3]Vancouver General Hospital

Introduction: Osteolytic bone lesions are prevalent in up to 90% of multiple myeloma (MM) patients. However, a lack of reliable, immunocompetent and rapid-onset MM bone lesion models impairs the development of novel treatments. The immunocompetent murine Vk*MYC transplant MM model mimics multiple aspects of human MM. Intravenous injection of Vk*MYC MM cells into C57BL/6 mice frequently results in early mortality due to splenomegaly and this impedes the development of osteolytic bone lesions, limiting their utility as a model. Here, we investigated various factors including cell concentration and cell source in conjunction with intrafemoral injection to enhance our understanding of osteolytic bone lesion development in the Vk*MYC MM mouse model. **Methods:** We used male and female

treatment. Other key eligibility criteria include measurable disease per 2016 IMWG criteria; ≥18 years of age; adequate bone marrow reserves and hepatic, renal, and cardiac function; and no prior treatment with elotuzumab, pomalidomide, or BCMA-directed immunotherapies. Linvoseltamab will be given in 28-day cycles, with step-up dosing to the full dose undertaken during Cycle 1. EPd treatment will also be given in 28-day cycles, according to the package inserts. Both treatment regimens will be given until disease progression or another defined reason for drug discontinuation. The study will take place at ~180 sites globally. A total of ~300 pts will be randomized (1:1) to IV linvoseltamab or EPd, stratified by prior anti-CD38 mAb exposure, International Staging System stage, and extramedullary plasmacytoma status. The primary endpoint is progression-free survival per IMWG criteria, determined by independent review committee (IRC). Key secondary endpoints are objective response rate (including rates of very good partial response or better and complete response or better, determined by IRC); MRD status; overall survival; and change in pain at Week 12 (Brief Pain Inventory-Short Form, Item 3). Incidence/severity of treatment-emergent AEs will also be assessed. Study enrollment is planned to begin in Q3 2023.

Fewer patients retreated with ide-cel experienced cytokine release syndrome (45.2% vs 80.6%) or investigator-identified neurotoxicity (3.2% vs 16%) than those on or after initial treatment. Induction of proinflammatory cytokines, indicating CAR T activation, was dampened during retreatment and minimal PD responses were observed. In 29 patients who received a second dose of ide-cel ranging from 300–450x10^6 CAR+ T cells, median Cmax following retreatment was 5.2-fold lower while median AUC0–28days was 8.6-fold lower than the initial infusion, despite most of the patients (23/29) receiving a higher target dose in the second infusion. CAR T cells expanding after retreatment were characterized by decreased proportions of CD4+ and CD8+ CAR+ subsets for proliferating (Ki67+) and TEM (CCR7–/CD45RA–) cells versus initial infusion. The magnitude of dampened CAR T activation and PD activity in retreatment trended higher in patients (19/31) who were anti-drug antibody (ADA) positive proximal to initiation of retreatment. **Conclusions:** A lower ORR was observed in patients following ide-cel retreatment compared with initial treatment. Ide-cel retreatment was characterized by suboptimal activation and expansion, consistent with the limited efficacy observed. ADA may be implicated in retreatment but does not fully explain the observed CAR T activation dampening that was observed across the entire retreatment cohort. The mechanisms underlying suboptimal ide-cel activation during retreatment remain not fully elucidated and are likely multifactorial and distinct from features characterizing suboptimal response to initial infusion.

Introduction: Osteolytic bone lesions are prevalent in up to 90% of multiple myeloma (MM) patients. However, a lack of reliable, immunocompetent and rapid-onset MM bone lesion models impairs the development of novel treatments. The immunocompetent murine Vk*MYC transplant MM model mimics multiple aspects of human MM. Intravenous injection of Vk*MYC MM cells into C57BL/6 mice frequently results in early mortality due to splenomegaly and this impedes the development of osteolytic bone lesions, limiting their utility as a model. Here, we investigated various factors including cell concentration and cell source in conjunction with intrafemoral injection to enhance our understanding of osteolytic bone lesion development in the Vk*MYC MM mouse model. **Methods:** We used male and female

C57BL/6 mice aged 6-8 weeks as recipients. Murine Vk*MYC MM cells of varying concentrations (0.1×10^6 to 1×10^6 cells/mouse) and origins (splenocytes and bone marrow (BM) cells) were transplanted intrafemorally into C57BL/6 mice. PBS-injected C57BL/6 mice were utilized as a control. MM development was monitored through weekly serum protein electrophoresis (SPEP). The hindlimbs and spines were imaged with X-Ray and μ-CT. In addition, MM cells from the spleen and forearm/hip bones were quantified via flow cytometry. **Results:** All mice in this study were successfully engrafted, surviving for 6 to 7 weeks post-injection. Based on the imaging and SPEP results, we observed a direct association between the quantity of injected cells and the severity of bone lesions and tumor burden. Moreover, the cell source (BM cells or splenocytes injected into the femur) played a significant role in the severity of bone lesions. Surprisingly, splenocytes caused more extensive lesions and 25-40% of Vk*MYC cells were present in spleens. In contrast, flow cytometry of BM cells derived from forearms and hip bones showed only 4-10% Vk*MYC cells. Every intrafemorally transplanted mouse developed bone lesions that were enriched in the injected femur (proximal and distal) and occasionally appeared in the tibias and/or non-injected femur, depending on the disease stage. No lesions were detected in the spine of any mice. **Conclusions:** We have observed that upon intrafemoral injection of Vk*MYC cells, the disease progression exhibits a sufficiently slow rate, allowing for the development of bone lesions even when a high cell count (1×10^6) is introduced. Additionally, splenocytes demonstrate a capacity to induce bone lesions similar to those caused by BM cells, even with an increased severity attributed to the heightened disease burden. In conclusion, disease dynamics as well as cell source determine the onset of bone lesions.

Introduction: Extramedullary disease (EMD) refers to the involvement of soft tissues due to hematogenous spread or the presence of a tumor mass adjacent to bones originating from focal skeletal lesions in patients with multiple myeloma (MM). Although EMD is generally associated with poor prognosis, survival outcomes can vary depending on the site and stage of involvement, as well as the response to therapy. **Methods:** This retrospective study analyzed the medical records of 419 adult patients with MM treated at a tertiary referral center in Türkiye between 2010 and 2022. Ninety-nine patients with confirmed extramedullary involvement based on pathological and/or radiological findings were included. Data were collected from hospital records and the management information system. The average follow-up time was found to be 40±31.5 months. **Results:** Twenty-seven percent of MM patients were found to have EMD. Extramedullary-extraosseous involvement (EM-E) was observed in 27 (27%) patients. Paraosseous involvement (EM-B) was seen in 72 (72%) patients. PET/CT was the most commonly used imaging modality (76%). Cytogenetic analysis was available for 73 patients, revealing high-risk cytogenetics in 16.4% of cases. Most commonly used induction regimen was bortezomib-cyclophosphamide-dexamethasone (VCD) regimen (36%). Median overall survival (OS) and progression-free survival (PFS) of the patients with EMD were 77 months (range: 58 - 95) and 49 months (range: 39 - 58), respectively. In the univariate analysis; advanced ISS staging (OS HR: 2.42, p = 0.024), high levels of serum Beta-2-Microglobulin (OS HR: 2.46, p = 0.020), and light chain disease (OS median survival 24 months / 78 months, p = 0.049) were associated with a worse OS. Secondary EMD, defined as the detection of EMD during MM follow-up, was associated with a worse PFS (HR: 2.87, p = 0.013). In the multivariate analysis; ASCT (OS HR: 0.26, p = 0.001) and low serum creatinine (OS HR: 1.21 p = 0.025) were independently associated with improved OS. Induction regimen groups showed comparable PFS and OS outcomes. The overall survival analysis for patients with high-risk cytogenetic features showed a decrease in survival (OS HR: 1.9, p = 0.259). **Conclusions:** EMD is an adverse prognostic factor in MM. Establishing standardized imaging methods and reporting systems is crucial for diagnosing EMD and clarifying the definitions of EM-E and EM-B. It is also important to conduct studies on biochemical and cytogenetic markers to identify patients at high risk for EMD, determine appropriate follow-up parameters and reach a consensus on treatment. Our study showed that various clinicals factors including ISS staging, levels of serum Beta-2-Microglobulin and creatinine and EMD subtypes, are associated with inferior outcome. With a median PFS of 79.5 months with ASCT compared to 30.1 months without ASCT, our findings emphasize the importance of ASCT in the management of MM patients with EMD.

Role the combination of FDG pet plus whole body MRI for staging patients in high risk smoldering myeloma: a prospective trial

Claudio Cerchione[1], Davide Nappi[2], Matteo Marchesini[2], Sonia Ronconi[2], Delia Cangini[2], Michela Ceccolini[2], Giorgia Simonetti[2], Gerardo Musuraca[2], Giovanni Martinelli[2], Alice Rossi[2]

[1]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy; [2]IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori"

Introduction: In SMM, it is really important to differentiate high risk SMM (HR-SMM), in which treatment could be available thanks to clinical trials. 2016 IMWG criteria state that detection of bone lesions is mandatory for diagnosis of multiple myeloma (MM) as well as ruling out them is essential for diagnosis of SMM. 18F-FDG PET with CT(FDG PET/TC) or whole body CT are indicated to assess lytic lesions. Magnetic resonance imaging (MRI),especially if the previous two are negative, is a diagnostic tool for identifying extra- or para-skeletal manifestations and complications, namely pathological fractures and spinal cord compression, as well as diagnostic tool for MM when > 1 lytic lesion is detected. Whole-

Body MRI (WB-MRI) is a cross-sectional imaging technique for the entire skeletal study, with high sensitivity in detecting bone lesions, not still widely available because of costs and technical reasons. Moreover, since MRI has a higher sensitivity for detecting higher bone marrow cellularity, which is a clue of plasmacellular infiltration without overt bone lytic lesions, WB-MRI can detect a diffuse pattern of marrow involvement. Nevertheless, the IMWG has not yet defined the MRI diffuse pattern as a criterion for symptomatic disease, then the routine detection of this pattern could be relevant in patients with SMM to possibly suggest a group of patients with higher risk of developing lytic lesions and so progression in MM. **Methods:** In our Institution, from January 2021 to January 2023, we performed a prospective trial enrolling 26 consecutive newly diagnosed HR-SMM, according to IMWG, in which WB-MRI was performed according to MY-RADS criteria in combination with FDG PET-CT(median age 56; range 36-85). **Results:** Interim analysis of the comparison between WB-MRI and FDG PET-CT, showed a discordance in 4/26 (15%). In particular, in 3/26 (12%) WB-MRI showed bone lesions that have lead to symptomatic MM diagnosis according to IMWG, while PET-CT was negative. In one case, PET-CT showed a diffuse uptake, not diagnostic for MM, while WB-MRI was negative. WB-MRI showed a 100% of accuracy in detecting SMM and MM. Therefore, WB-MRI has lead to a modification of the prognosis and treatment (observation in SMM vs treatment in MM) in 3/26 patients (11%) (i.e. Fig. 1). In 5/23 (22%) SMM WB-MRI showed a slight diffuse alteration pattern of bone marrow without any overt lytic bone lesion, which could be a potential prognostic evidence. **Conclusions:** Our preliminary results support a fundamental role of WB-MRI plus FDG PET/CT in newly diagnosed high risk SMM, which could modify prognosis and treatment. In particular, WB-MRI plus FDG PET/CT could be more accurate in the detection of bone lesions than FDG PET/CT alone, being able to anticipate MM diagnosis and its treatment. Moreover, a diffuse pattern of marrow involvement could be detected in some HR-SMM patients without any overt lytic lesions: it is questionable if this group is associated with a rapid progression in lytic lesions and so in symptomatic MM.

Role of the combination of FDG-PET plus whole body MRI for staging newly diagnosed and relapsed/refractory multiple myeloma: a prospective trial

Claudio Cerchione[1], Davide Nappi[2], Matteo Marchesini[2], Sonia Ronconi[2], Delia Cangini[2], Michela Ceccolini[2], Giorgia Simonetti[2], Gerardo Musuraca[2], Giovanni Martinelli[2], Alice Rossi[2]

[1]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy; [2]IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori"

Introduction: The integration of FDG-PET/TC and WB-MRI in the diagnosis of MM may results in higher accuracy to detect bone lesion compared to them alone. This could be translated into better outcomes if early detection of myeloma defining events leads to earlier induction or re-induction treatments. **Methods:** In our Institution, from January 2021 to January 2023, we performed a prospective trial enrolling 73 consecutive newly diagnosed and relapsed/refractory MM (median age 63 years - range 85-35), according to IMWG, in which WB-MRI was performed according to MY-RADS criteria in combination with FDG PET/CT. 31/73 (42%) had a newly diagnosed MM, 25/73 (34%) were in follow-up after autologous stem cell transplantation and 17/73 (23%) patients were affected by relapsed/refractory MM. Subsequently, in 2 cases WB- MRI were aborted and not diagnostic so patients were excluded from the final analysis. In our Institution, from January 2021 to January 2023, we performed a prospective trial enrolling 73 consecutive newly diagnosed and relapsed/refractory MM (median age 63 years - range 85-35), according to IMWG, in which WB-MRI was performed according to MY-RADS criteria in combination with FDG PET/CT. 31/73 (42%) had a newly diagnosed MM, 25/73 (34%) were in follow-up after autologous stem cell transplantation and 17/73 (23%) patients were affected by relapsed/refractory MM. Subsequently, in 2 cases WB- MRI were aborted and not diagnostic so patients were excluded from the final analysis. **Results:** In these 71 patients: 52/71 (73%) cases of concordance of WB-MRI and 18F PET-CT, 18/71 (25%) cases of discordance. In this group 15/18 (83%) cases FDG-PET/CT was negative and WB-MRI showed positive findings according to MYRADS criteria (5 micronodular pattern, 9 diffuse pattern e 1 focal pattern) (Figure 1 Newly diagnosed MM – diffuse pattern in WB-MRI, PET negativity), in 3/18 (17%) FDG-PET/CT was positive for focal lesions and WB-MRI was negative. IMWG criteria showed concordance with WB-MRI data in 16/18 (89 %), in 2/18 (11%) case of follow-up after autologous stem cell transplantation PET-CT showed a relapsed focal lesion while WB-MRI was negative. Accuracy of WB-MRI was 69/71 (97%), whilst PET- CT was 55/71 (77%).These results are in agreement with the literature data about the ability of WB-MRI to depict diffuse and micronodular pattern of bone marrow infiltration. **Conclusions:** Our preliminary results support ta potential complementary role of WB-MRI and FDG PET/CT findings, on the management of patients with MM at both diagnosis and relapse. To date, there is no wide availability of WB-MRI because in concerning about costs and technical issues, but data are consistent with its possible future leading role in MM diagnostic work-up.

Introduction: The integration of FDG-PET/TC and WB-MRI in the diagnosis of MM may results in higher accuracy to detect bone lesion compared to them alone. This could be translated into better outcomes if early detection of myeloma defining events leads to earlier induction or re-induction treatments. **Methods:** In our Institution, from January 2021 to January 2023, we performed a prospective trial enrolling 73 consecutive newly diagnosed and relapsed/refractory MM (median age 63 years - range 85-35), according to IMWG, in which WB-MRI was performed according to MY-RADS criteria in combination with FDG PET/CT. 31/73 (42%) had a newly diagnosed MM, 25/73 (34%) were in follow-up after autologous stem cell transplantation and 17/73 (23%) patients were affected by relapsed/refractory MM. Subsequently, in 2 cases WB- MRI were aborted and not diagnostic so patients were excluded from the final analysis. In our Institution, from January 2021 to January 2023, we performed a prospective trial enrolling 73 consecutive newly diagnosed and relapsed/refractory MM (median age 63 years - range 85-35), according to IMWG, in which WB-MRI was performed according to MY-RADS criteria in combination with FDG PET/CT. 31/73 (42%) had a newly diagnosed MM, 25/73 (34%) were in follow-up after autologous stem cell transplantation and 17/73 (23%) patients were affected by relapsed/refractory MM. Subsequently, in 2 cases WB- MRI were aborted and not diagnostic so patients were excluded from the final analysis. **Results:** In these 71 patients: 52/71 (73%) cases of concordance of WB-MRI and 18F PET-CT, 18/71 (25%) cases of discordance. In this group 15/18 (83%) cases FDG-PET/CT was negative and WB-MRI showed positive findings according to MYRADS criteria (5 micronodular pattern, 9 diffuse pattern e 1 focal pattern) (Figure 1 Newly diagnosed MM – diffuse pattern in WB-MRI, PET negativity), in 3/18 (17%) FDG-PET/CT was positive for focal lesions and WB-MRI was negative. IMWG criteria showed concordance with WB-MRI data in 16/18 (89 %), in 2/18 (11%) case of follow-up after autologous stem cell transplantation PET-CT showed a relapsed focal lesion while WB-MRI was negative. Accuracy of WB-MRI was 69/71 (97%), whilst PET- CT was 55/71 (77%).These results are in agreement with the literature data about the ability of WB-MRI to depict diffuse and micronodular pattern of bone marrow infiltration. **Conclusions:** Our preliminary results support ta potential complementary role of WB-MRI and FDG PET/CT findings, on the management of patients with MM at both diagnosis and relapse. To date, there is no wide availability of WB-MRI because in concerning about costs and technical issues, but data are consistent with its possible future leading role in MM diagnostic work-up.

Body MRI (WB-MRI) is a cross-sectional imaging technique for the entire skeletal study, with high sensitivity in detecting bone lesions, not still widely available because of costs and technical reasons. Moreover, since MRI has a higher sensitivity for detecting higher bone marrow cellularity, which is a clue of plasmacellular infiltration without overt bone lytic lesions, WB-MRI can detect a diffuse pattern of marrow involvement. Nevertheless, the IMWG has not yet defined the MRI diffuse pattern as a criterion for symptomatic disease, then the routine detection of this pattern could be relevant in patients with SMM to possibly suggest a group of patients with higher risk of developing lytic lesions and so progression in MM. **Methods:** In our Institution, from January 2021 to January 2023, we performed a prospective trial enrolling 26 consecutive newly diagnosed HR-SMM, according to IMWG, in which WB-MRI was performed according to MY-RADS criteria in combination with FDG PET-CT(median age 56; range 36-85). **Results:** Interim analysis of the comparison between WB-MRI and FDG PET-CT, showed a discordance in 4/26 (15%). In particular, in 3/26 (12%) WB-MRI showed bone lesions that have lead to symptomatic MM diagnosis according to IMWG, while PET-CT was negative. In one case, PET-CT showed a diffuse uptake, not diagnostic for MM, while WB-MRI was negative. WB-MRI showed a 100% of accuracy in detecting SMM and MM. Therefore, WB-MRI has lead to a modification of the prognosis and treatment (observation in SMM vs treatment in MM) in 3/26 patients (11%) (i.e. Fig. 1). In 5/23 (22%) SMM WB-MRI showed a slight diffuse alteration pattern of bone marrow without any overt lytic bone lesion, which could be a potential prognostic evidence. **Conclusions:** Our preliminary results support a fundamental role of WB-MRI plus FDG PET/CT in newly diagnosed high risk SMM, which could modify prognosis and treatment. In particular, WB-MRI plus FDG PET/CT could be more accurate in the detection of bone lesions than FDG PET/CT alone, being able to anticipate MM diagnosis and its treatment. Moreover, a diffuse pattern of marrow involvement could be detected in some HR-SMM patients without any overt lytic lesions: it is questionable if this group is associated with a rapid progression in lytic lesions and so in symptomatic MM.

Introduction: Multiple myeloma (MM) is an incurable blood cancer. It is linked to a variety of symptoms, so mastery would allow for early diagnosis and management, particularly in less developed regions, including Sub-Saharan Africa. The aim of this study was to investigate the clinical and radiological symptoms, outcomes, and management characteristics of MM in sub-Saharan African patients. **Methods:** Four databases (PubMed, Web of Science, Global Index Medicus, and Excerpta Medica Databases) were searched in a systematic database and gray literature search and the design of the study has followed PRISMA standard guidelines. **Results:** This study included 32 articles in total, corresponding to 21172 cases. The overall prevalence of multiple myeloma in sub-Saharan African patients was 10.34% (95% CI: 6.35–15.15). Patients with blood diseases were the most affected, with a prevalence of 18.49% (95% CI: 8.60–31.02). The main radiological symptoms of MM in sub-Saharan Africa were bone lesions (lytic bone lesions, osteolytic lesions, and bone deficiency, essentially) and fractures (long bone fractures, vertebral compression fractures, and vertebral collapse, essentially). The main clinical symptoms at diagnosis of MM in sub-Saharan Africa were musculoskeletal (bone pain and lumbar pain, essentially), haematological (clinical anemia), and constitutional (asthenia). The majority of patients with MM in sub-Saharan Africa were in Stage III. The prevalence of death was 38% (95% CI: 27.31–49.28), with a 5-year survival rate of 16.54% (95% CI: 11.33–22.47) in patients with MM in sub-Saharan Africa. Palliative care was the most commonly used treatment (analgesic), followed by chemotherapy (Alexanian essentially) and combination chemotherapy (Vincristine /Carmustine/ Adriamycin /Prednisone essentially). **Conclusions:** This study has a low risk of bias (100% of studies). The findings suggest that multiple myeloma is a serious health condition in sub-Saharan African patients, and the need to educate the community and clinicians on the characteristics of the disease, for early and optimal management.

Giaccone", Palermo, Italy; [2]Laboratory of Advanced Diagnosis and Biomedical Research (CLADIBIOR), University of Palermo, Palermo, Italy; [3]Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties (ProMISE), University of Palermo, Palermo, Italy; [4]Pathology Unit, Department of Scienze per la Promozione della Salute e Materno Infantile, University of Palermo, Palermo, Italy; [5]Department of Medicine-DIMED, Institute of Radiology, University of Padova, Padova, Italy; [6]Department of Biomedicine, Neurosciences and Advanced Diagnostics (BiND), University of Palermo, 90141 Palermo, Italy; [7]University of Palermo

Introduction: Multiple myeloma (MM) is a hematologic malignancy characterized by the presence of at least 10% of clonal plasma cells (cPCs) in bone marrow (BM). Bone lytic lesions are common in MM patients, and low-dose whole body CT (LD-CT) is the preferred imaging method for evaluating MM-associated bone disease in individuals with monoclonal gammopathy (MG). In this study, by using innovative radiomic techniques that extract additional information (namely "features") from images, such as tissue density and heterogeneity, we aimed to assess the potential of LD-CT radiomic analysis in differentiating pre-malignant conditions from MM within the MG population and predicting patients' outcomes. **Methods:** We collected data from 106 consecutive suspected MG patients who underwent LD-CT from late 2019 to February 2022. The patient cohort consisted of 10 MGUS, 16 SMM, 59 newly diagnosed MM, 18 MM patients undergoing surveillance CT scans during treatment, and 3 healthy subjects. 35 radiomic features were extracted from texture analysis performed through LifeX software. Additionally, we included CBC count, laboratory tests, disease stage, and percentage of BM cPCs from medical records. Flow cytometry data from 27 BM patient samples were analyzed using FlowCT, a recently developed bioinformatic pipeline, to investigate differences in the BM immune microenvironment. **Results:** Unsupervised hierarchical clustering analysis revealed three distinct patient groups based on the distribution of radiomic features. Interestingly, two of these groups were enriched with SMM (SMM-like) or MGUS (MGUS-like) patients. When focusing exclusively on MM patients, this classification demonstrated prognostic relevance, with patients belonging to MGUS or SMM-like groups experiencing a significantly longer I line progression-free survival (PFS) regardless of treatment used (p=0.01). We also observed a strong correlation between five radiomic features and disease status, with a significant reduction features correlated with tissue skewness and an increase in those associated with tissue uniformity moving from MGUS to SMM or MM (p=0.008), possibly indicating tissue replacement by cPCs (in the absence of evident lytic lesions). Additionally, we found associations between radiomic-identified subgroups and BM immune cell composition. MGUS-like MM patients showed an increase in activated T lymphocytes (p=0.01), while SMM-like MM patients exhibited an increase in activated monocytes (p< 0.01). The MM-exclusive group displayed an intermediate profile between the two. **Conclusions:** Our findings highlight how specific cell types within the MM microenvironment can influence BM density, affecting CT results and, ultimately, patients' prognosis. We provide preliminary evidence of the potential utility of CT, beyond detecting bone lytic lesions, in identifying individuals at a higher risk of disease progression or predicting MM outcomes.

An effective approach using ensemble learning based on a random subspace method in laser-induced breakdown spectroscopy to diagnose blood cancer

Gao Jiajia[1], Zuo Zhiyu[1], Chu Yanwu[2], Chen Feng[2], Guo Lianbo[2], Zhu Guoqing[1], Qi Jianwei[1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College; [2]Wuhan National Laboratory for Optoelectronics (WNLO), Huazhong University of Science and Technology

Introduction: Blood cancer poses serious threats to human health, and the diagnosis of blood cancer is still facing certain challenges. The chemometrics method combined with laser-induced breakdown spectroscopy (LIBS) can be used for cancer detection. However, it was easily influenced by the spectral feature redundancy and noise, resulting in a low accuracy rate. Thus, it is essential to develop more effective methods for blood cancer diagnosis. **Methods:** We proposed an approach using LIBS combined with the ensemble learning based on the random subspace method (RSM). The blood cancer serum samples including lymphoma, multiple myeloma (MM), chronic myelogenous leukemia (CML) and acute myeloid leukemia (AML) were dripped onto a boric acid substrate for LIBS spectrum collection. **Results:** The results showed that these four cancer types could be distinguished by the RSM-LDA model. Compare with linear discriminant analysis (LDA) and k nearest neighbors (kNN), the RSM-LDA model has the highest average accuracy rate and Area Under Curve (AUC), suggesting the RSM-LDA model has the best classification performance. With the RSM-LDA model, the average accuracy rates for lymphoma vs healthy control (HC), MM vs HC, CML vs HC and AML vs HC were from 94.38%, 94.61%, 94.49% and 94.33% to 96.62%, 98.78%, 96.54% and 98.77%, respectively. For cancerous samples classification, the detectable rate was evaluated with the average detectable rates of lymphoma vs HC, MM vs HC, CML vs HC and AML vs HC and were 89.86%, 92.94%, 89.17% and 93.33%, respectively. Furthermore, the average accuracy rate was improved to 91.00%, and 8% of MM spectra and 6% of lymphoma spectra were misidentified to CML calculated. For blood cancer types identification, the detectable rates of lymphoma, MM, CML and AML were 93.75%, 90.00%, 86.67% and 93.33%, respectively, which means the RSM-LDA model can improve the diagnostic performance. **Conclusions:** In conclusion, the RSM-LDA model provides an effective pattern recognition method for LIBS analysis in blood cancer discrimination.

Spinal involvement predicts for inferior overall survival (OS), progression free survival (PFS) and higher skeletal related events risk in multiple myeloma (MM) patients: a single center experience

Nikolaos Kanellias[1], Agapi Parcharidou[1], Kate Xu[2], William Wilson[3], Rodothea Americanou[4], Adam Benton[5], Sean Molloy[5], Jan Herzog[5], Rikin Hargunani[5], Rakesh Popat[2], Jonathan Sive[2], Lydia Lee[2], Annabel McMillan[2], Xenofon Papanikolaou[2], Neil Rabin[2], Kwee Yong[2], Charalampia Kyriakou[2]

[1]London Northwest University Healthcare NHS trust; [2]NHS University College London Hospital, London, United Kingdom; [3]Cancer Research UK and UCL Cancer Trials Centre, University College London, London, United Kingdom; [4]University College London Hospitals NHS Foundation Trust; [5]Royal National Orthopaedic Hospital NHS Trust

Introduction: Skeletal related events (SRES) include pathological fractures, radiotherapy (XRT), spinal cord compression (SCC) and surgical interventions (SI) and represent frequent complications of MM osteolytic bone disease (MM OBD) with significant impact on patients' survival. Data from previous studies indicate that spine is the most common site affected by OBD. The aim of this study was to explore the impact of OBD and spinal involvement on survival of MM patients. **Methods:** We retrospectively evaluated the electronic records of 905 newly diagnosed MM (NDMM) patients followed up in a single center between 2018-2023. **Results:** We identified 905 NDMM patients (541 (60%) males, 454 (68%) White, 102 (15%) Black, 61 (9%) Asian, and 43 (8%) of mixed or other ethnic origin. Myeloma subtype was IgG in 509 (78%), IgA in 138 (21%) and light chain in 199 patients. Among patients with known cytogenetics, 118/576 (20%) had high risk (HRC). At diagnosis 692/905 (75%) patients had OBD as per IMWG criteria.405 (45%) patients presented with at least one SRE at diagnosis, 258 with single (186 fractures, 6 SCC, 55 XRT, 11 surgery) and 147 with SREs combinations. Fractures distribution: C1-C7(15), T1-T6 (63), T7-T12 (180), lumbar (131), femora (4), clavicles (5), sacrum (3), pubic rami (4), sternum (9), humeri (8) and ribs (30). 396/905 (44%) patients with OBD, had spinal involvement (vertebral fractures, lytic lesions, and diffuse infiltration of the spinal column). The management of spinal involvement included radiotherapy (87), spinal bracing (157) and 74 surgical interventions (36 cement augmentation, 38 metal spinal operation). On univariable analysis, patients with OBD at diagnosis had significantly worse OS than those without (HR = 2.09, 95% CI 1.11-3.94, p=0.02). This remained significant after adjustment for age, sex, heavy and light chain type (HR 2.54, 95% CI 1.16-5.54, p=0.02). Spinal involvement at diagnosis had significantly worse OS (HR 2.95 95% CI 1.61-5.39 p < 0.001), PFS (HR 1.23 95% CI 1.00-1.52 p=0.05). and remained the only significant independent factor for increased SREs risk (HR 4.19 HR2.09-8.40 p< 0.001). Age (HR 1.04 95% CI 1.00-1.08 p=0.05), application of brace at diagnosis (HR 2.09 95% CI 1.01-4.35p=0.05) and the presence of HRC (HR 2.63 95% CI 1.29-5.38, p=0.008) remained independent prognostic factors

Introduction: Skeletal related events (SRES) include pathological fractures, radiotherapy (XRT), spinal cord compression (SCC) and surgical interventions (SI) and represent frequent complications of MM osteolytic bone disease (MM OBD) with significant impact on patients' survival. Data from previous studies indicate that spine is the most common site affected by OBD. The aim of this study was to explore the impact of OBD and spinal involvement on survival of MM patients. **Methods:** We retrospectively evaluated the electronic records of 905 newly diagnosed MM (NDMM) patients followed up in a single center between 2018-2023. **Results:** We identified 905 NDMM patients (541 (60%) males, 454 (68%) White, 102 (15%) Black, 61 (9%) Asian, and 43 (8%) of mixed or other ethnic origin. Myeloma subtype was IgG in 509 (78%), IgA in 138 (21%) and light chain in 199 patients. Among patients with known cytogenetics, 118/576 (20%) had high risk (HRC). At diagnosis 692/905 (75%) patients had OBD as per IMWG criteria.405 (45%) patients presented with at least one SRE at diagnosis, 258 with single (186 fractures, 6 SCC, 55 XRT, 11 surgery) and 147 with SREs combinations. Fractures distribution: C1-C7(15), T1-T6 (63), T7-T12 (180), lumbar (131), femora (4), clavicles (5), sacrum (3), pubic rami (4), sternum (9), humeri (8) and ribs (30). 396/905 (44%) patients with OBD, had spinal involvement (vertebral fractures, lytic lesions, and diffuse infiltration of the spinal column). The management of spinal involvement included radiotherapy (87), spinal bracing (157) and 74 surgical interventions (36 cement augmentation, 38 metal spinal operation). On univariable analysis, patients with OBD at diagnosis had significantly worse OS than those without (HR = 2.09, 95% CI 1.11-3.94, p=0.02). This remained significant after adjustment for age, sex, heavy and light chain type (HR 2.54, 95% CI 1.16-5.54, p=0.02). Spinal involvement at diagnosis had significantly worse OS (HR 2.95 95% CI 1.61-5.39 p < 0.001), PFS (HR 1.23 95% CI 1.00-1.52 p=0.05). and remained the only significant independent factor for increased SREs risk (HR 4.19 HR2.09-8.40 p< 0.001). Age (HR 1.04 95% CI 1.00-1.08 p=0.05), application of brace at diagnosis (HR 2.09 95% CI 1.01-4.35p=0.05) and the presence of HRC (HR 2.63 95% CI 1.29-5.38, p=0.008) remained independent prognostic factors

on overall survival in multivariable analysis in patients with OBD at diagnosis. **Conclusions:** The presence of OBD had a profound impact on OS in NDMM patients. Spinal involvement, that was identified in 44% of the patients, was found to be an independent significant prognostic factor for inferior PFS, OS and higher SREs risk. These findings, warrant focus on optimizing further early spinal disease management, to improve survival outcomes in this subgroup of MM patients.

Real-world evidence of bisphosphonates and denosumab for multiple myeloma

Nieves Lopez-Muñoz[1], Gema Hernández-Ibarburu[2], Rafael Alonso[1], Jose Maria Sanchez[1], Clara Cuellar[1], M Teresa Cedena[1], Ana Jimenez-Ubieto[1], Maria Calbacho[1], Rosa Ayala[1], Laura Meloni[3], David Perez-Rey[4], Joaquín Martínez-López[5]

[1]Hospital 12 de Octubre; [2]Biomedical Informatics Group, Universidad Politécnica de Madrid; [3]TriNetX, LLC, Cambridge, MA USA; [4]Biomedical Informatics Group, Universidad Politécnica de Madrid, Spain; [5]Hematología Hospital 12 de Octubre, Madrid, Spain

Introduction: Bisphosphonates are widely used in multiple myeloma; but only a randomized clinical have showed that zolendronic acid improved survival as well as reduce the number of bone events. On the other hand, Denosumab, a monoclonal antibody targeting RANKL, appears to reduce skeletal-related events, with no known effect on overall survival in patients with multiple myeloma. The objective of this study is analyze the impact of bisphosphonates treatment and denosumab in a large cohort of patients with multiple myeloma. We used data from TriNetx, a global federated health research platform that includes patients from Europe and US. **Methods:** Patients had symptomatic multiple myeloma (ICD-10-CM code C90.0) diagnosed between 2007 and 2022. Comparator cohorts included 3707 MM patients from US and EMEA Collaborative Networks. Analyses have been performed after propensity scoring matching by age, sex, bone fractures in the 3 months prior to diagnosis, bone disease and previous treatment with corticosteroids, calcium and vitamin D. Patients treated with bisphosphonates included: Pamidronate and Zolendronic acid. Kaplan−Meier analysis was used to estimate survival probabilities, and between-group differences were tested using the log-rank test and hazard ratio. **Results:** First of all, we compared patients treated with bisphosphonates vs no treatment (2310 patients in each cohort). Patients treated with bisphosphonates had a significant longer overall survival (OS) (HR 0.748 (0.665-0.841, p< 0.001). (Figure 1). Thereafter, we compared patients treated with denosumab vs no treatment (968 patients in each cohort). Patients treated with denosumab had a significant longer overall survival (OS) (HR 0.708 (0.597-0.839, p< 0.001). (Figure 2). Finally, we compared patients treated with bisphosphonates vs denosumab (960 patients in each cohort). No difference in overall survival (OS) between the two groups of patients (HR 1.070 (0.907-1.263, p=0.271). (Figure 3). Regarding the increased risk of fractures or the need for orthopedic surgery, no differences were found between the patient groups. **Conclusions:** This large-scale study based on real-world data confirms the bisphosphonates and denosumab prolong survival in MM, with no differences between them.

Comparison of whole-body imaging in multiple myeloma with respect to lytic involvement and presence of extramedullary disease

Jiri Minarik[1], Michaela Jurinova[2], Vojtech Mahr[2], Eva Buriankova[1], Miroslav Herman[1], Jan Hrbek[1], Vojtech Latal[1], Petra Krhovska[1], Jaroslav Bacovsky[1], Tomas Pika[1]

[1]University Hospital Olomouc; [2]Faculty of Medicine and Dentistry, Palacky University Olomouc

Introduction: The presence of osteolytic involvement in multiple myeloma (MM) is one of the halmarks of the disease. In approximately 5-20% of patients, prognostically negative paramedullary and/or extramedullary disease (EM) is detectable, based on the imaging technique used. Conventional X-ray has only limited sensitivity in the detection of lytic involvement, especially in the spine, and a very low sensitivity for EM. Therefore, more sophisticated whole-body imaging techniques are recommended, such as magnetic resonance imaging (MRI), low dose computed tomography (LD-CT) or positron emission tomography with computed tomography (PET/CT). Each of them has slightly different outcomes and limitations. Our aim was to compare the sensitivity of selected whole-body imaging techniques in the detection of osteolytic involvement and EM. **Methods:** We performed a large retrospective assessment of 411 MRI, 304 PET/CT, 269 Technetium-sestaMIBI and 151 LD-CT findings in 270 patients with MM, smoldering myeloma (SMM) and monoclonal gammopathy of undetermined significance (MGUS). We assessed the presence and number of lytic lesions by each technique and similarly the presence and number of EM. In 80 patients we had concurrent data from PET/CT, MRI and MIBI at the same time, therefore we compared these patients and sensitivity of the three techniques separately. We used statistical software IBM SPSS Statistics, version 23. For the comparison of the techniques, we used Chi-quadrat test, McNemara test, Friedman test and Wilcoxon pair test with Bonferroni correction, the level of statistical significance was $p < 0,05$. **Results:** The imaging techniques had following sensitivity in detection of osteolytic lesions: LD-CT 76,8%, MRI 66,4%, PET/CT 53,6% and MIBI 38,7%. Most examinations detected 3 and more lesions, the presence of only 1 lesion was up to 6% and 2 lesions up to 4% in all techniques. When assessing the presence of EM, the most sensitive technique was PET/CT – 31,3%, followed by LD/CT – 13,9% and MRI – 6,1%, the lowest number of EM were identified by MIBI – 3,0%. Within the assessment of the 80 patients with concurrent imaging by 3 techniques, the most sensitive method for lytic bone assessment was MRI with 81,2%, followed by PET/CT – 58,7% and MIBI – 43,7%. The detection of EM was following: MRI 7,6%, PET/CT 21,2% and MIBI 2,5%; the level of concordance between MRI and PET/CT was 86,3%, between MRI and MIBI 93,8% and between PET/CT and MIBI 80%. **Conclusions:** The whole-body imaging techniques used for

on overall survival in multivariable analysis in patients with OBD at diagnosis. **Conclusions:** The presence of OBD had a profound impact on OS in NDMM patients. Spinal involvement, that was identified in 44% of the patients, was found to be an independent significant prognostic factor for inferior PFS, OS and higher SREs risk. These findings, warrant focus on optimizing further early spinal disease management, to improve survival outcomes in this subgroup of MM patients.

Comparison between MRI and PET/CT in the diagnosis of plasmacytomas and their clinical and radiologicla follow-up

Isabel Vicuna[1], Francisco Garrido[1], Nieves Gomez[1], Itaxo Galan[1], Valentina Castillo[1], Beatriz Aguado[1], Gonzalo Benzo[1], Carmen Jimenez[1], Adrian Alegre[1]

[1]Hospital de La Princesa

Introduction: There is a debate on the technique of choice for the study of plasmacytomas (PCM) between Whole Body Magnetic Resonance Imaging (WBMRI) and Positron Emission Computed Tomography (PET/CT)(PCM). We present our comparative experience with both tests. **Methods:** Multicenter, observational, retrospective study between 2010 and 2023 N 66, age 64 (30-94). 18 (27.3%) were solitary PCM; 25 (37.9%) MM with simultaneous PCM at diagnosis; and 23 (34.8%) MM with subsequent relapsed PCM. 52 cases were osseous (78.8%) and 14 extramedullary (EM) (21.2%) PCMs. The 25% received only radiotherapy (RT), 13% only chemotherapy (CT) and 45% both treatments. The median number of lines was 3 (1-4). In 49(76%) cases WBMRI and PET/CT were compared from baseline, with a maximum interval between both tests of 30 days. The cases of spinal cord compression and the differences between clinical and radiological response were analyzed, as well as the correlation with the rest of the clinical variables. **Results:** Of the 49 patients with both tests (76%), MRI detected pathology in 48 (97.9%) and PET/CT in 41 (83.7%). The difference in detection percentage (14.3%) between both tests was statistically significant (p=0.0391). MRI detected spinal cord compression in 9 cases (18.4%) while PET/CT failed to detect in none. The difference in detection percentage between both tests was statistically significant (p=0.0039). The concordance in the detection of bone PCM was very good. In the skull, cervical spine, dorsal spine, lumbar spine, pelvis, MMSS, costal grid and clavicles it was 100% (k=1, p< 0.001); and in the sternum 98% (k= 0.898, p< 0.001). In the detection of EM PCM the concordance was moderate: 87.8% (k=0.596, p< 0.001). PET/CT failed to detect 2 orbital, 2 meningeal and 1 nasal plasmacytomas (35.7% of cases), while MRI was able to identify such lesions. MRI studies are more useful in these locations, due to their higher spatial resolution and soft tissue contrast. We did not observe significant differences between clinical and radiological response. The highest percentage of complete response was in solitary plasmacytomas (83.33%). The subgroup with the worst clinical response was that of patients with the appearance of plasmacytoma at relapse/progression of MM **Conclusions:** In our study the two techniques had percentages detection rates higher than 80%. MRI was superior in the diagnosis of plasmacytomas compared to PET/CT, with a detection difference of 14.3% (95% CI: 0.9%-27.6%). We observed very good concordance between the two techniques in bone PCM and moderate in EM. Our experience suggests that MRI is preferable to PET/CT in the study of spinal plasmacytomas (including suspected spinal cord compression) and head. Clinical and radiological systemic evaluation are essential for the comprehensive assessment of the patient with plasmacytoma.

Whole body low dose CT (WBLDCT), as initial imaging modality for newly diagnosed multiple myeloma patients: experience from a teritary care center in North India

Sanjeev Yadav[1], Souvik Saha[1], Dinesh Chandra[1], Manish Kumar Singh[1], Khaiqur Rahman[1], Ruchi Gupta[1], Hira Lal[1], Rajesh Kashyap[1]

[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences

Introduction: For decades, the main imaging modality to detect bony lesions in multiple myeloma was whole body skeletal survey by X ray. However, x ray had limited sensitivity and specificity. Hence, CT, MRI and PET CT came to Fore-front with better sensitivity and specificity as well as detection of extramedullary soft tissue disease. The disadvantage with CT was the high radiation dose required; hence, whole body low dose CT protocols were developed and have become the one of the investigation of choice to detect lytic lesions in multiple myeloma along with whole body MRI. We herein present Whole body low dose CT (WBLDCT) findings in Serial patients of plasma cell dyscrasia for past 1 year. **Methods:** We retrospectively collected the data from Hospital information system (HIS) & Radiology department for our serial patients of plasma cell dyscrasia from Jan 2022 to Dec 2022 **Results:** The patients included were 38, out of which 29 cases of multiple myeloma, 5 cases of MGUS, 1 case of smoldering multiple myeloma, 1 case of non secretory myeloma, 1 case of plasmacytoma and 1 case of plasma cell leukemia. There was presence of lytic lesions in 20 out of the 29 patients of multiple myeloma. The most commonly affected site was vertebra (36.8%) followed by sacrum and pelvis (28.9%), ribs and sternum (26.3%), skull (21.1%) and long bones (21.1%). In 7 patients (18.4%), lytic lesions were involving 3 or more sites. In 4 patients, bone lesions were the only CRAB feature present, which upgraded the diagnosis from SMM to multiple myeloma. Extramedullary disease was detected in 5 patients (13.2%). 17 out of the 20 patients (85%) with bone lesions were ISS Stage 3 whereas only 11 such patients (55%) belonged to R ISS Stage 3. We further analyzed the 7 patients who had 3 or more lytic lesions. Extramedullary disease was present in only 2 of the 7 patients. On serum immunofixation, 3 of these patients were IgG kappa, 2 were kappa light chain, 1 was IgA lambda and 1 was lambda light chain. FISH panel did not reveal any mutations in 5 patients while the rest of the 2 patients had gain 1q. All of the 7 patients belonged to ISS Stage 3. 4 patients had R ISS Stage 2 while 3 patients had R ISS Stage 3. **Conclusions:** Imaging plays a very important role in the initial diagnosis and Surveillance of multiple myeloma patients. Although our study was limited by a

the assessment of myeloma bone disease have different sensitivity in the evaluation of lytic lesions as well as extramedullary disease. For the assessment of bone lesions, MRI seems to be most sensitive, still, with very similar outcomes in CT based techniques. For EM, there is high concordance between PET/CT, MRI and MIBI, still PET/CT is able to detect the highest percentage of extramedullary lesions. Supported by MH CZ – DRO (FNOl, 00098892).

Introduction: There is a debate on the technique of choice for the study of plasmacytomas (PCM) between Whole Body Magnetic Resonance Imaging (WBMRI) and Positron Emission Computed Tomography (PET/CT)(PCM). We present our comparative experience with both tests. **Methods:** Multicenter, observational, retrospective study between 2010 and 2023 N 66, age 64 (30-94). 18 (27.3%) were solitary PCM; 25 (37.9%) MM with simultaneous PCM at diagnosis; and 23 (34.8%) MM with subsequent relapsed PCM. 52 cases were osseous (78.8%) and 14 extramedullary (EM) (21.2%) PCMs. The 25% received only radiotherapy (RT), 13% only chemotherapy (CT) and 45% both treatments. The median number of lines was 3 (1-4). In 49(76%) cases WBMRI and PET/CT were compared from baseline, with a maximum interval between both tests of 30 days. The cases of spinal cord compression and the differences between clinical and radiological response were analyzed, as well as the correlation with the rest of the clinical variables. **Results:** Of the 49 patients with both tests (76%), MRI detected pathology in 48 (97.9%) and PET/CT in 41 (83.7%). The difference in detection percentage (14.3%) between both tests was statistically significant (p=0.0391). MRI detected spinal cord compression in 9 cases (18.4%) while PET/CT failed to detect in none. The difference in detection percentage between both tests was statistically significant (p=0.0039). The concordance in the detection of bone PCM was very good. In the skull, cervical spine, dorsal spine, lumbar spine, pelvis, MMSS, costal grid and clavicles it was 100% (k=1, p< 0.001); and in the sternum 98% (k= 0.898, p< 0.001). In the detection of EM PCM the concordance was moderate: 87.8% (k=0.596, p< 0.001). PET/CT failed to detect 2 orbital, 2 meningeal and 1 nasal plasmacytomas (35.7% of cases), while MRI was able to identify such lesions. MRI studies are more useful in these locations, due to their higher spatial resolution and soft tissue contrast. We did not observe significant differences between clinical and radiological response. The highest percentage of complete response was in solitary plasmacytomas (83.33%). The subgroup with the worst clinical response was that of patients with the appearance of plasmacytoma at relapse/progression of MM **Conclusions:** In our study the two techniques had percentages detection rates higher than 80%. MRI was superior in the diagnosis of plasmacytomas compared to PET/CT, with a detection difference of 14.3% (95% CI: 0.9%-27.6%). We observed very good concordance between the two techniques in bone PCM and moderate in EM. Our experience suggests that MRI is preferable to PET/CT in the study of spinal plasmacytomas (including suspected spinal cord compression) and head. Clinical and radiological systemic evaluation are essential for the comprehensive assessment of the patient with plasmacytoma.

Whole body low dose CT (WBLDCT), as initial imaging modality for newly diagnosed multiple myeloma patients: experience from a teritary care center in North India

Sanjeev Yadav[1], Souvik Saha[1], Dinesh Chandra[1], Manish Kumar Singh[1], Khaiqur Rahman[1], Ruchi Gupta[1], Hira Lal[1], Rajesh Kashyap[1]

[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences

Introduction: For decades, the main imaging modality to detect bony lesions in multiple myeloma was whole body skeletal survey by X ray. However, x ray had limited sensitivity and specificity. Hence, CT, MRI and PET CT came to Fore-front with better sensitivity and specificity as well as detection of extramedullary soft tissue disease. The disadvantage with CT was the high radiation dose required; hence, whole body low dose CT protocols were developed and have become the one of the investigation of choice to detect lytic lesions in multiple myeloma along with whole body MRI. We herein present Whole body low dose CT (WBLDCT) findings in Serial patients of plasma cell dyscrasia for past 1 year. **Methods:** We retrospectively collected the data from Hospital information system (HIS) & Radiology department for our serial patients of plasma cell dyscrasia from Jan 2022 to Dec 2022 **Results:** The patients included were 38, out of which 29 cases of multiple myeloma, 5 cases of MGUS, 1 case of smoldering multiple myeloma, 1 case of non secretory myeloma, 1 case of plasmacytoma and 1 case of plasma cell leukemia. There was presence of lytic lesions in 20 out of the 29 patients of multiple myeloma. The most commonly affected site was vertebra (36.8%) followed by sacrum and pelvis (28.9%), ribs and sternum (26.3%), skull (21.1%) and long bones (21.1%). In 7 patients (18.4%), lytic lesions were involving 3 or more sites. In 4 patients, bone lesions were the only CRAB feature present, which upgraded the diagnosis from SMM to multiple myeloma. Extramedullary disease was detected in 5 patients (13.2%). 17 out of the 20 patients (85%) with bone lesions were ISS Stage 3 whereas only 11 such patients (55%) belonged to R ISS Stage 3. We further analyzed the 7 patients who had 3 or more lytic lesions. Extramedullary disease was present in only 2 of the 7 patients. On serum immunofixation, 3 of these patients were IgG kappa, 2 were kappa light chain, 1 was IgA lambda and 1 was lambda light chain. FISH panel did not reveal any mutations in 5 patients while the rest of the 2 patients had gain 1q. All of the 7 patients belonged to ISS Stage 3. 4 patients had R ISS Stage 2 while 3 patients had R ISS Stage 3. **Conclusions:** Imaging plays a very important role in the initial diagnosis and Surveillance of multiple myeloma patients. Although our study was limited by a

the assessment of myeloma bone disease have different sensitivity in the evaluation of lytic lesions as well as extramedullary disease. For the assessment of bone lesions, MRI seems to be most sensitive, still, with very similar outcomes in CT based techniques. For EM, there is high concordance between PET/CT, MRI and MIBI, still PET/CT is able to detect the highest percentage of extramedullary lesions. Supported by MH CZ – DRO (FNOl, 00098892).

Introduction: There is a debate on the technique of choice for the study of plasmacytomas (PCM) between Whole Body Magnetic Resonance Imaging (WBMRI) and Positron Emission Computed Tomography (PET/CT)(PCM). We present our comparative experience with both tests. **Methods:** Multicenter, observational, retrospective study between 2010 and 2023 N 66, age 64 (30-94). 18 (27.3%) were solitary PCM; 25 (37.9%) MM with simultaneous PCM at diagnosis; and 23 (34.8%) MM with subsequent relapsed PCM. 52 cases were osseous (78.8%) and 14 extramedullary (EM) (21.2%) PCMs. The 25% received only radiotherapy (RT), 13% only chemotherapy (CT) and 45% both treatments. The median number of lines was 3 (1-4). In 49(76%) cases WBMRI and PET/CT were compared from baseline, with a maximum interval between both tests of 30 days. The cases of spinal cord compression and the differences between clinical and radiological response were analyzed, as well as the correlation with the rest of the clinical variables. **Results:** Of the 49 patients with both tests (76%), MRI detected pathology in 48 (97.9%) and PET/CT in 41 (83.7%). The difference in detection percentage (14.3%) between both tests was statistically significant (p=0.0391). MRI detected spinal cord compression in 9 cases (18.4%) while PET/CT failed to detect in none. The difference in detection percentage between both tests was statistically significant (p=0.0039). The concordance in the detection of bone PCM was very good. In the skull, cervical spine, dorsal spine, lumbar spine, pelvis, MMSS, costal grid and clavicles it was 100% (k=1, p< 0.001); and in the sternum 98% (k= 0.898, p< 0.001). In the detection of EM PCM the concordance was moderate: 87.8% (k=0.596, p< 0.001). PET/CT failed to detect 2 orbital, 2 meningeal and 1 nasal plasmacytomas (35.7% of cases), while MRI was able to identify such lesions. MRI studies are more useful in these locations, due to their higher spatial resolution and soft tissue contrast. We did not observe significant differences between clinical and radiological response. The highest percentage of complete response was in solitary plasmacytomas (83.33%). [1]University of Arkansas for Medical Sciences; [2]Myeloma Center, University of Arkansas for Medical Sciences

Introduction: Osteolytic lesions are a hallmark of multiple myeloma (MM). We have previously demonstrated that cystatin E/M (CST6) suppresses MM bone disease by blocking osteoclast differentiation. Recombinant CST6 protein has a short serum half-life in a mouse model. As a therapeutic agent, CST6 protein concentrations should be maintained at relatively high levels. B cell maturation antigen (BCMA)-specific chimeric antigen receptor (CAR)-T cell therapies are associated with high response rates in the treatment of MM. Fourth-generation CARs have been developed and are ideal to deliver CST6, which is a secretory protein, close to nascent focal lesions. Here, we demonstrate that BCMA-CST6-CAR-T cells simultaneously ablate MM cells and suppress osteolytic lesions. **Methods:** The BCMA-CST6-CAR vector contains BCMA-scFv and a 4-1BB co-activation domain with CD3ζ. A P2A self-cleaving peptide was inserted between CAR and CST6. CAR-T cells were incubated with MM1.S cells at a ratio of 5:1 for 24 h. To evaluate the in vivo anti-tumor activity and anti-bone resorption of BCMA-CST6-CAR-T cells, we injected MM1.S cells expressing luciferase into NSG mice. On day 7, MM-bearing mice received CAR-T cells. These mice were sacrificed on day 35, mouse serum CST6 concentrations were evaluated by ELISA, and mouse tibiae were collected for μCT and TRAP staining. **Results:** The percentage of lysed MM1.S cells was 77.2% after 24 h co-culturing with CAR-T cells. No difference in killing was observed between BCMA-CAR-T group and BCMA-CST6-CAR-T group. T cell activation marker CD69 was significantly increased in BCMA-CST6-CAR-T (70.9%) group compared to the MOCK-CAR-T group (9.2%). Bioluminescence imaging of MM-bearing mice revealed that BCMA-CST6-CAR-T cells affected excellent antitumor activity, yielding near-complete tumor clearance by day 21. Again, BCMA-CST6-CAR-T cells and BCAM-CAR-T cells showed very similar effects on inhibiting tumor growth. CST6 serum concentration was significantly higher in the BCAM-CST6-CAR-T group (938.4 ng/ml) compared to the MOCK group (60.9 ng/ml) and BCMA-CAR-T group (64.2 ng/ml) ($P< 0.001$), indicating that BCMA-CST6-CAR-T cells secrete high levels of CST6 protein in vivo. μCT images of mouse tibiae showed that BCMA-CST6-CAR-T cells significantly suppressed osteolytic lesions in MM-bearing mice. TRAP staining of mouse tibia sections demonstrated that the BCMA-CST6-CAR-T cells significantly reduced osteoclast numbers and the proportion of bone surface occupied by osteoclasts. **Conclusions:** This work presents a rational approach to engineering BCMA-CST6-CAR-T cells that can effectively target MM cells and release large amounts of CST6 protein, which efficiently suppresses osteolytic lesions in MM.

Intestinal nitrogen-recycling bacteria contribute to osteolysis in multiple myeloma

Qin Yang[1], Yinghong Zhu[2], Xingxing Jian[1], Yanjuan He[1], Jing Liu[1], Wen Zhou[3]

[1]Third Xiangya Hospital, Central South University; [2]Cancer Research Institute, School of Basic Medical Sciences, Central South University, Changsha, Hunan, China; [3]State Key Laboratory of Experimental Hematology,Cancer Research Institute, School of Basic Medical Sciences, Central South University, Changsha, Hunan, China

Introduction: Gut microbiota in bone remodeling and regulation has been defined recently. Our previous work has demonstrated that intestinal nitrogen-recycling bacteria enriched in multiple myeloma (MM) and promoted MM progression. However, whether this significantly enriched gut nitrogen-recycling bacteria regulate myeloma bone remodeling remained ill-defined. **Methods:** Shotgun metagenomic sequencing and 16s rRNA qPCR were utilized to screen differential species. Fecal microbiota and single bacteria transplantation were conducted to confirm osteolysis. Further experiments were performed to explore the mechanisms. During the project, the sampling procedure was approved by the Central South University (CSU) Medical Ethics Committee, and animal work was performed under the guidelines of the Institutional Animal Care and local veterinary office and ethics committee of CSU. **Results:** Intestinal nitrogen-recycling bacteria is markedly increased in MM patients with osteolysis. To explore the differential bacteria of MM patients with osteolysis, shotgun metagenomic sequencing was performed and demonstrated the domination of pathological bacteria and the reduced probiotics. Especially, the abundance of E. cloacae was significantly increased, as well as a significant correlation between the severity of osteolysis was defined. Intestinal nitrogen-recycling bacteria promote osteolysis in MM. To further assess the effect of enriched bacteria on osteolysis, fecal microbiota transplantation from MM patients with osteolysis showed more severe osteolysis in MM mice, demonstrating lower BV/TV, Tb.N, and Tb.Th of micro-CT, and higher concentrations of CTX-1 and PINP. Additionally, longitudinal analysis of the colonization demonstrated the gradual domination of E. cloacae. Furthermore, transplantation with E. cloacae confirmed the function of osteolysis in MM mice. NH_4^+ produced by E. cloacae bolsters MM osteoclastogenesis. Finally, to explore the functional mechanisms, a concentration of NH_4^+ was detected and showed a significant increase in MM with osteolysis and a positive correlation withE. cloacae. Meanwhile, analysis of clinical characteristics demonstrated a positive correlation between the concentration of NH_4^+ and osteolysis in MM patients. Furthermore, NH_4^+ was confirmed to promote osteolysis in MM mice, as well as accelerate osteoclastogenesis in vitro with an increased expression of CCL3 detected by WB in MM cells and ELISA in MM mice. Additionally, the higher expression deaminase gene dcd was detected and then a strain of deleted dcd of E. cloacae was testified

small sample size, this is one the first studies describing Whole body low dose whole body CT in myeloma patients in Indian Scenario.

Introduction: In recent years, minimal residual disease (MRD) reduction up to undetectable level has become an independent prognostic factor in Multiple Myeloma (MM) and MRD assessment might become a helpful tool to guide treatment. Here we present the implementation of a highly sensitive Next Generation Sequencing (NGS) workflow for MRD assessment in MM daily clinical practice. **Methods:** 299 newly diagnosed transplant-eligible MM patients (pts) were included in the study between 2016 and 2023, and screened by NGS for clonotype (ID) definition. MRD was assessed pre-maintenance, at the achievement of at least very good partial response, and, thereafter, once a year. A commercial assay covering IgH and IgK genes (Invivoscribe) was employed for ID definition in bone marrow (BM) CD138+ plasma cells (PCs), and for MRD measurement in BM whole blood cells. Data were analyzed by Lymphotrack Dx and MRD software (Invivoscribe). **Results:** ID screening was possible in all pts, by using 70ng of starting DNA and by sequencing firstly IgH-FR1 and Igk and, in cases of no ID identification, also IgH-FR2 and -FR3. Overall, 490 clonal sequences were identified in 281/299 pts (94%). Polyclonal results (6%) were mainly due to low CD138+ PCs percentage in pre (<1.6%) and post (< 84%) enrichments, as well as to low cells number (p-value <.05). MRD trackable sequences were selected thanks to an originality score defined according to V and J regions specificities, CDR3 insertions and/or deletions and clonality percentage. Overall, 246 IgH (177 FR1, 43 FR2 and 26 FR3) and 35 IgK IDs were selected, with a median clonality percentage of 64.5% (2.5%-98.6%). In 10 pts, 2 IDs were identified and used for MRD monitoring, to improve MRD analysis' sensitivity. For MRD detection, 2µg input DNA's triplicates were sequenced with a 1,5 million reads depth. A confidence ≥90% was required to define the sensitivity level. So far, 317 MRD measurements were evaluated in 111/281 pts, (at least one per pts), with an overall median follow-up of 47 months (range 6-83). MRD results were defined negative, with 10-5 sensitivity in 80% of cases, in 146/317 cases; positive in 117/317 cases, with MRD ranging from 1.1x10-5 to 2.3x10-4; low positive (when measurements had < 90% result's confidence) in 54/317 cases, with MRD ranging from 9.9x10-9 to 9,8x10-5. In 50/111 pts, MRD was also measured pre-maintenance (67 evaluations), with 24/67 MRD negative results. **Conclusions:** In conclusion, NGS was successfully implemented as best tool in the daily practice of MM pts. The clonotype was defined in almost all pts, thus allowing MRD molecular monitoring. CD138+ PCs' both quality and amount were critical for successful clonotyping. For MRD assessment, a regular samples' workflow (at least 5 per week) was needed to both limit costs and maintain an acceptable reporting time (7 days). Results confirm the feasibility of MRD assessment by NGS in the daily practice, supporting the upcoming need of MM pts personalized management. **Acknowledgment:** AIRC IG2018-22059.

Liquid biopsy monitoring is more sensitive than alternative techniques in extramedullary multiple myeloma

Nicholas Bingham[1], Daniel Wong[1], Antonia Reale[1], Tiffany Khong[1], Sridurga Mithraprabhu[1], Andrew Spencer[1]

[1]Alfred Health-Monash University, Melbourne, VIC, Australia

Introduction: Extramedullary disease (EMD) affects 30% of multiple myeloma (MM) patients, predicting poor overall survival due to aggressive disease kinetics and multi-drug resistance. Current methods for detection and monitoring include PET/CT scans; alternatives such as bone marrow (BM) biopsies and consensus response criteria (CRC) are limited as EMD is frequently non-secretory or with minimal BM involvement. EMD is associated with driver mutations (DM) in the MAPK pathway (KRAS, NRAS and BRAF). We have shown DM are detectable in cell free DNA (cfDNA) in EMD patients and now sought to clarify the role of cfDNA characterisation in EMD patients. **Methods:** Plasma was collected in Streck DNA tubes. cfDNA was extracted using QIAGEN QIAamp® Circulating Nucleic Acid Kit. DM were identified by whole genome sequencing or whole exome sequencing. Once identified, droplet digital PCR was used to detect DM in cfDNA at additional timepoints, including prior to EMD development, after treatment and at relapse. **Results:** 13 patients were included. 100% had the EMD DM detected in the blood at the time of EMD diagnosis with variant allele frequency (VAF) ranging from 0.05% to 37.63%. At diagnosis, low cfDNA VAF associated with low disease burden on PET/CT, however high VAFs do not necessarily reflect PET/CT burden and may reflect factors such as tumour necrosis. Eight patients had at least two cfDNA timepoints. Changes in the cfDNA VAF over time mirrored PET-CT-defined response to therapy and relapse. We then compared cfDNA levels after therapy with other response parameters- PET/CT, CRC and EuroFlow minimal residual disease (MRD). Response assessments by cfDNA appeared complementary to PET/CT, with 3 cases showing incongruity between PET/CT and cfDNA; 2 had cfDNA positivity with PET/CT negativity and 1 cfDNA negativity but PET/CT positivity. In patients with secretory

to alleviate osteolysis in MM mice. **Conclusions:** Altogether, our present findings demonstrate that enriched intestinal nitrogen-recycling bacteria contribute to osteolysis by interacting with host metabolism, which reports on the characteristic gut microbiome and offers a new potential therapeutic strategy for the intervention of MM with osteolysis.

Introduction: In recent years, minimal residual disease (MRD) reduction up to undetectable level has become an independent prognostic factor in Multiple Myeloma (MM) and MRD assessment might become a helpful tool to guide treatment. Here we present the implementation of a highly sensitive Next Generation Sequencing (NGS) workflow for MRD assessment in MM daily clinical practice. **Methods:** 299 newly diagnosed transplant-eligible MM patients (pts) were included in the study between 2016 and 2023, and screened by NGS for clonotype (ID) definition. MRD was assessed pre-maintenance, at the achievement of at least very good partial response, and, thereafter, once a year. A commercial assay covering IgH and IgK genes (Invivoscribe) was employed for ID definition in bone marrow (BM) CD138+ plasma cells (PCs), and for MRD measurement in BM whole blood cells. Data were analyzed by Lymphotrack Dx and MRD software (Invivoscribe). **Results:** ID screening was possible in all pts, by using 70ng of starting DNA and by sequencing firstly IgH-FR1 and Igk and, in cases of no ID identification, also IgH-FR2 and -FR3. Overall, 490 clonal sequences were identified in 281/299 pts (94%). Polyclonal results (6%) were mainly due to low CD138+ PCs percentage in pre (<1.6%) and post (< 84%) enrichments, as well as to low cells number (p-value <.05). MRD trackable sequences were selected thanks to an originality score defined according to V and J regions specificities, CDR3 insertions and/or deletions and clonality percentage. Overall, 246 IgH (177 FR1, 43 FR2 and 26 FR3) and 35 IgK IDs were selected, with a median clonality percentage of 64.5% (2.5%-98.6%). In 10 pts, 2 IDs were identified and used for MRD monitoring, to improve MRD analysis' sensitivity. For MRD detection, 2µg input DNA's triplicates were sequenced with a 1,5 million reads depth. A confidence ≥90% was required to define the sensitivity level. So far, 317 MRD measurements were evaluated in 111/281 pts, (at least one per pts), with an overall median follow-up of 47 months (range 6-83). MRD results were defined negative, with 10-5 sensitivity in 80% of cases, in 146/317 cases; positive in 117/317 cases, with MRD ranging from 1.1x10-5 to 2.3x10-4; low positive (when measurements had < 90% result's confidence) in 54/317 cases, with MRD ranging from 9.9x10-9 to 9,8x10-5. In 50/111 pts, MRD was also measured pre-maintenance (67 evaluations), with 24/67 MRD negative results. **Conclusions:** In conclusion, NGS was successfully implemented as best tool in the daily practice of MM pts. Liquid biopsy monitoring is more sensitive than alternative techniques in extramedullary multiple myeloma

Nicholas Bingham[1], Daniel Wong[1], Antonia Reale[1], Tiffany Khong[1], Sridurga Mithraprabhu[1], Andrew Spencer[1]

[1]Alfred Health-Monash University, Melbourne, VIC, Australia

Introduction: Extramedullary disease (EMD) affects 30% of multiple myeloma (MM) patients, predicting poor overall survival due to aggressive disease kinetics and multi-drug resistance. Current methods for detection and monitoring include PET/CT scans; alternatives such as bone marrow (BM) biopsies and consensus response criteria (CRC) are limited as EMD is frequently non-secretory or with minimal BM involvement. EMD is associated with driver mutations (DM) in the MAPK pathway (KRAS, NRAS and BRAF). We have shown DM are detectable in cell free DNA (cfDNA) in EMD patients and now sought to clarify the role of cfDNA characterisation in EMD patients. **Methods:** Plasma was collected in Streck DNA tubes. cfDNA was extracted using QIAGEN QIAamp® Circulating Nucleic Acid Kit. DM were identified by whole genome sequencing or whole exome sequencing. Once identified, droplet digital PCR was used to detect DM in cfDNA at additional timepoints, including prior to EMD development, after treatment and at relapse. **Results:** 13 patients were included. 100% had the EMD DM detected in the blood at the time of EMD diagnosis with variant allele frequency (VAF) ranging from 0.05% to 37.63%. At diagnosis, low cfDNA VAF associated with low disease burden on PET/CT, however high VAFs do not necessarily reflect PET/CT burden and may reflect factors such as tumour necrosis. Eight patients had at least two cfDNA timepoints. Changes in the cfDNA VAF over time mirrored PET-CT-defined response to therapy and relapse. We then compared cfDNA levels after therapy with other response parameters- PET/CT, CRC and EuroFlow minimal residual disease (MRD). Response assessments by cfDNA appeared complementary to PET/CT, with 3 cases showing incongruity between PET/CT and cfDNA; 2 had cfDNA positivity with PET/CT negativity and 1 cfDNA negativity but PET/CT positivity. In patients with secretory

disease, cfDNA was more sensitive compared to CRC, with DM detectable in cfDNA in 3 patients in a CR. cfDNA assessment also outperformed MRD testing, with 40% of MRD negative timepoints demonstrating cfDNA positivity. Importantly, changes in VAF were prognostic. Patients achieving cfDNA negativity had the longest remissions (median 23.5 months) whereas those who did not demonstrated short time to progression (median 6 months). In 2 patients who experienced EMD relapse from cfDNA negativity, cfDNA became positive prior to overt relapse by PET/CT, CRC, or BM MRD. Finally, DM were detectable in cfDNA prior to the initial development of EMD, in one case two years before EMD diagnosis. Liquid biopsies from an additional 24 patients are being analysed. **Conclusions:** In EMD patients MAPK activating DM are detectable in cfDNA. cfDNA is complementary to PET/CT scanning, more sensitive than BM MRD and CRC, and is a predictor of EMD relapse. DM exist in cfDNA prior to EMD, and their detection may allow tailored monitoring strategies and early intervention.

Failure to clear circulating tumor cells after one week of daratumumab, bortezomib and dexamethasone is associated with a reduced progression-free survival for myeloma patients

Christian Bryant[1], Edward Abadir[1], Nicole Wong Doo[2], Adam Bryant[3], Georgia McCaughan[4], Shihong Yang[1], Vinay Vanguru[1], Tracy King[1], Douglas Joshua[1], Phoebe Joy Ho[1]

[1]Royal Prince Alfred Hospital; [2]Concord Repatriation and General Hospital; [3]Liverpool Hospital; [4]St Vincents Hospital

Introduction: Obtaining bone marrow MRD negativity after induction therapy is associated with a superior PFS and OS. Conversely, patients with a high level of circulating tumor cells (CTC) in the peripheral blood prior to commencing front-line therapy have inferior outcomes. Less is known about the impact of CTC level at relapse, and the implications of early changes in CTC levels are not known. In Australia, Bortezomib, Daratumumab and Dexamethasone (BDd) is only available as 2nd line therapy, hence almost all patients receive this combination making them a group who are treated homogeneously and are highly representative of MM patients. We hypothesized that CTC level and their early changes would predict long term outcome in MM patients receiving BDd at 2nd line. **Methods:** Patients receiving BDd at second line were identified. Peripheral blood was collected prior to therapy and on day 8. Blood was analyzed within 24 hours using the Euroflow next-generation flow cytometry platform and the Infinocyte CTC analysis database. **Results:** 28 patients have been analysed with a median follow-up of 232 days (range 46-722). The median limit of detection was 0.00035%, and the median limit of quantification was 0.00081%. CTC were detectable prior to treatment in 27/28 patients (median value 0.0087%, range 0.00081-6.8%). CTC were detectable in 10/28 on Day 8 of cycle 1 (median value 0.0054%, range 0.00028 – 0.33%). There were no differences in age, sex or prior Bortezomib exposure between those who cleared CTC by day 8 and those who did not. Failure to clear CTC was associated with an increased incidence of high risk FISH (50% vs 17%) and gain 1q (50% vs 28%), increased exposure to prior Lenalidomide (60% vs 23%), and a shorter median time from diagnosis (835 vs 1239 days) when compared with those who cleared CTC. Patients who had higher levels of CTC prior to commencing second line (>0.01%) had a shorter PFS than those who did not (median PFS 400 days vs not reached, p=0.0482). The failure to clear CTC by day 8 had a strong correlation with PFS. Patients who failed to clear had a median PFS of 359 days whilst median PFS is not yet reached for those who cleared CTC (p=0.0194). **Conclusions:** This data suggests that failure to clear CTC from the blood within one week of second line BDd predicts patients who are destined for brief remissions. This can be achieved without the need for invasive bone marrow biopsies. Early identification of patients who will have short remissions could allow for a trial of early intensification of therapy to improve outcomes.

Hevylite in the multiple myeloma patient pathway

Lauren Campbell[1], Ross Sadler[1], Karthik Ramasamy[1], Jaimal Kothari[1]

[1]Oxford University Hospitals NHS Foundation Trust, Oxford, UK

Introduction: The majority of multiple myeloma (MM) patients are now achieving very deep responses. The most sensitive disease detection techniques are currently bone marrow assays. However, as bone marrow (BM) sampling is invasive and unpleasant for patients it is important to investigate whether blood-based assays could be equally or more informative of disease status. The HevyliteTM assay (The Binding Site, UK) evaluates serum heavy/light chains (HLC) for IgG, IgA and IgM M-proteins. This study assessed whether the HLC assay could act as an effective marker for disease in the bone marrow of treated MM patients and evaluate the prognostic utility of HLC measurements at best response and relapse time points. **Methods:** Patients: 104 MM (IgG or IgA), either prior to transplant or during chemotherapy. Median follow up = 18 months. Routine M-proteins were performed alongside HLC testing. A BM flow cytometry MRD assay was tested in parallel if relevant. Disease response was set according to IMWG criteria. Baseline was the initial sample taken post-therapy. **Results:** At pre- and post-transplant there was significant agreement between HLC measurements and BM-MRD, with uHLC being the most sensitive (86%) and HLCr the most specific (100%). Survival analysis showed significantly inferior survival in patients with abnormal uHLC or HLCr results post-transplant. Follow up HLC values correlated with depth of response, uHLC was abnormal in 60% of complete response (CR) patients. At best response uHLC gave a significant difference in survival, with this significance remaining in CR patients only. Addition of the free light chain assay into analysis did not improve the significance of survival differences. For relapsed patients, comparisons of M-protein with HLC parameters at best response vs. prior to clinical relapse showed uHLC was the only marker to be significantly different between the two time points in IgG and IgA patients. Patients in stable disease did not experience a significant change in uHLC levels.

disease, cfDNA was more sensitive compared to CRC, with DM detectable in cfDNA in 3 patients in a CR. cfDNA assessment also outperformed MRD testing, with 40% of MRD negative timepoints demonstrating cfDNA positivity. Importantly, changes in VAF were prognostic. Patients achieving cfDNA negativity had the longest remissions (median 23.5 months) whereas those who did not demonstrated short time to progression (median 6 months). In 2 patients who experienced EMD relapse from cfDNA negativity, cfDNA became positive prior to overt relapse by PET/CT, CRC, or BM MRD. Finally, DM were detectable in cfDNA prior to the initial development of EMD, in one case two years before EMD diagnosis. Liquid biopsies from an additional 24 patients are being analysed. **Conclusions:** In EMD patients MAPK activating DM are detectable in cfDNA. cfDNA is complementary to PET/CT scanning, more sensitive than BM MRD and CRC, and is a predictor of EMD relapse. DM exist in cfDNA prior to EMD, and their detection may allow tailored monitoring strategies and early intervention.

The median limit of detection was 0.00035%, and the median limit of quantification was 0.00081%. CTC were detectable prior to treatment in 27/28 patients (median value 0.0087%, range 0.00081-6.8%). CTC were detectable in 10/28 on Day 8 of cycle 1 (median value 0.0054%, range 0.00028 – 0.33%). There were no differences in age, sex or prior Bortezomib exposure between those who cleared CTC by day 8 and those who did not. Failure to clear CTC was associated with an increased incidence of high risk FISH (50% vs 17%) and gain 1q (50% vs 28%), increased exposure to prior Lenalidomide (60% vs 23%), and a shorter median time from diagnosis (835 vs 1239 days) when compared with those who cleared CTC. Patients who had higher levels of CTC prior to commencing second line (>0.01%) had a shorter PFS than those who did not (median PFS 400 days vs not reached, p=0.0482). The failure to clear CTC by day 8 had a strong correlation with PFS. Patients who failed to clear had a median PFS of 359 days whilst median PFS is not yet reached for those who cleared CTC (p=0.0194). **Conclusions:** This data suggests that failure to clear CTC from the blood within one week of second line BDd predicts patients who are destined for brief remissions. This can be achieved without the need for invasive bone marrow biopsies. Early identification of patients who will have short remissions could allow for a trial of early intensification of therapy to improve outcomes.

Hevylite in the multiple myeloma patient pathway

Lauren Campbell[1], Ross Sadler[1], Karthik Ramasamy[1], Jaimal Kothari[1]

[1]Oxford University Hospitals NHS Foundation Trust, Oxford, UK

Introduction: The majority of multiple myeloma (MM) patients are now achieving very deep responses. The most sensitive disease detection techniques are currently bone marrow assays. However, as bone marrow (BM) sampling is invasive and unpleasant for patients it is important to investigate whether blood-based assays could be equally or more informative of disease status. The HevyliteTM assay (The Binding Site, UK) evaluates serum heavy/light chains (HLC) for IgG, IgA and IgM M-proteins. This study assessed whether the HLC assay could act as an effective marker for disease in the bone marrow of treated MM patients and evaluate the prognostic utility of HLC measurements at best response and relapse time points. **Methods:** Patients: 104 MM (IgG or IgA), either prior to transplant or during chemotherapy. Median follow up = 18 months. Routine M-proteins were performed alongside HLC testing. A BM flow cytometry MRD assay was tested in parallel if relevant. Disease response was set according to IMWG criteria. Baseline was the initial sample taken post-therapy. **Results:** At pre- and post-transplant there was significant agreement between HLC measurements and BM-MRD, with uHLC being the most sensitive (86%) and HLCr the most specific (100%). Survival analysis showed significantly inferior survival in patients with abnormal uHLC or HLCr results post-transplant. Follow up HLC values correlated with depth of response, uHLC was abnormal in 60% of complete response (CR) patients. At best response uHLC gave a significant difference in survival, with this significance remaining in CR patients only. Addition of the free light chain assay into analysis did not improve the significance of survival differences. For relapsed patients, comparisons of M-protein with HLC parameters at best response vs. prior to clinical relapse showed uHLC was the only marker to be significantly different between the two time points in IgG and IgA patients. Patients in stable disease did not experience a significant change in uHLC levels.

In all analyses the HLC assay showed increased sensitivity and utility over the M-protein technique. **Conclusions:** Blood-based assays can be used prior to bone marrow analysis to help influence decisions and improve patient experience. This strategy can also impact patient follow up post initial treatment: 1. At best response, an abnormal uHLC or HLCr suggests a positive MRD status, meaning a possible reduction or delay in the requirement for bone marrow assessment. 2. All patients in ≥VGPR should have HLC performed alongside conventional assays during follow up. 3. If uHLC values become abnormal over follow up then it should be assumed that the patient is about to undergo relapse. The measurement of HLC values increases the sensitivity for detecting MRD, giving further clarification of response status and predicting early relapse.

Multiple myeloma patient perceptions of minimal residual disease testing

Jay Hydren[1], Jorge Arturo Hurtado Martinez[1], Felipe Flores Quiroz[1], Patricia Alejandra Flores Pérez[1], Andrea Isabel Robles Espinoza[1], Andrea Jimena Cuevas Vicencio[1], Marilú Nájera Flores[1], Eduardo Franco Hernandez[1], Ana Sahagun Sanchez Aldana[1], Nathan Sweeney[1], Jennifer Ahlstrom[1]

[1]HealthTree Foundation

Introduction: Minimal residual disease (MRD) testing is a valuable tool for detecting residual malignant cells in multiple myeloma (MM) patients (pts). MRD negativity has a strong predictive power and is linked to favorable outcomes in various diseases and treatments. However, not all MM pts are aware of this testing method and whether it could be integrated into their disease management. This study aimed to evaluate the awareness and perception of MRD testing in MM pts. **Methods:** HealthTree® Cure Hub for Multiple Myeloma, an online portal for pts with plasma cell dyscrasias, was used to conduct a 10-question survey to investigate the awareness, use, and opinions of MRD testing for MM pts. The statistical analysis was performed with R, R Studio, Knitr, and LaTex. Chi-square and T-Tests were used to evaluate if responses were different between pts confirmed to have had or not had MRD testing. Alpha was set at 0.05 with a two-tailed test. **Results:** A total of 635 pts from HealthTree Cure Hub answered the survey between September 30th 2022 to October 31st, 2022. Of the total participants, 486 were diagnosed with MM (83%), and most of them were reported as being in remission (60%). Validated medical records were available for 289 pts allowing for a comparison between pts confirmed to have had MRD testing and those that have yet to use the test. From the sample with validated MRD status, 81% of pts correctly identified they have had an MRD test, while 19% did not know they had an MRD test or were unsure. In contrast, 60% of pts correctly reported they never had an MRD test, but 40% of pts incorrectly reported they had had an MRD test or were unsure. Interestingly, only 15% of pts answered not being aware of MRD testing, and 36% were somewhat or slightly familiar with the MRD test and, as expected, pts validated to have had MRD testing reported to be more familiar with it (5-point Likert scale: 3.8±1.2 v. 3.2±1.2, $p < 0.001$). The majority of pts that were familiar with the test found it to be useful (96%) and would recommend it (84%). Additionally, more than half of the pts (77%) reported being interested in learning more about MRD testing. The top two sources of information for learning about MM care options were: doctor/care team (89%) and patient support/advocacy groups (e.g., HealthTree, MMRF) / online community (78%). **Conclusions:** This survey investigated MRD testing awareness, usage, and opinions among a large sample of pts with MM. More than half of pts lacked MRD testing usage or knowledge, and 30% of the validated cohort had incorrect knowledge of their MRD status. Nevertheless, among pts familiar with MRD testing, a high proportion found it useful and would recommend it to others. Moreover, a considerable number of pts reported interest in learning more about MRD testing. These findings underscore the need for increased awareness and understanding of MRD testing among pts with MM.

Introduction: Despite improvement in treatments, multiple myeloma (MM) remains an incurable malignancy. There is currently interest within the MM community to explore the validity of using predictors of overall survival (OS) such as minimal residual disease (MRD). Best clinical response (BCR) to treatment is a well-defined and standardised ordinal outcome scale captured in MM clinical trials and quality care registries. The aim of this study was to determine whether BCR to treatment could be used to predict OS when modelling real-world MM disease and treatment pathways. **Methods:** Risk equations controlling for age, sex, and disease severity were estimated using the Australia and New Zealand Myeloma & Related Diseases Registry data on approximately 3,600 MM patients diagnosed between 2011 and 2022. Multinominal logit regression including patient's complete treatment history was used to assign chemotherapy regimens to patients. Parametric survival analysis was used to estimate OS, chemotherapy duration, and treatment-free intervals for up to six lines of therapy. Ordered logit regression was used to predict BCR to treatment and sequential logit regressions were used to predict receipt of stem cell transplant and/or maintenance therapy after induction therapy. These were incorporated into a discrete-event individual simulation model which was then used to predict OS based on BCR to treatment. **Results:** The results show that the extremes of BCR are strong predictors of OS in MM, with patients achieving Complete Remission or Very Good Partial Response having the longest OS and patients with Progressive Disease the shortest OS. However, the discriminatory power of Partial Response versus Minimal Response

In all analyses the HLC assay showed increased sensitivity and utility over the M-protein technique. **Conclusions:** Blood-based assays can be used prior to bone marrow analysis to help influence decisions and improve patient experience. This strategy can also impact patient follow up post initial treatment: 1. At best response, an abnormal uHLC or HLCr suggests a positive MRD status, meaning a possible reduction or delay in the requirement for bone marrow assessment. 2. All patients in ≥VGPR should have HLC performed alongside conventional assays during follow up. 3. If uHLC values become abnormal over follow up then it should be assumed that the patient is about to undergo relapse. The measurement of HLC values increases the sensitivity for detecting MRD, giving further clarification of response status and predicting early relapse.

Introduction: Despite improvement in treatments, multiple myeloma (MM) remains an incurable malignancy. There is currently interest within the MM community to explore the validity of using predictors of overall survival (OS) such as minimal residual disease (MRD). Best clinical response (BCR) to treatment is a well-defined and standardised ordinal outcome scale captured in MM clinical trials and quality care registries. The aim of this study was to determine whether BCR to treatment could be used to predict OS when modelling real-world MM disease and treatment pathways. **Methods:** Risk equations controlling for age, sex, and disease severity were estimated using the Australia and New Zealand Myeloma & Related Diseases Registry data on approximately 3,600 MM patients diagnosed between 2011 and 2022. Multinominal logit regression including patient's complete treatment history was used to assign chemotherapy regimens to patients. Parametric survival analysis was used to estimate OS, chemotherapy duration, and treatment-free intervals for up to six lines of therapy. Ordered logit regression was used to predict BCR to treatment and sequential logit regressions were used to predict receipt of stem cell transplant and/or maintenance therapy after induction therapy. These were incorporated into a discrete-event individual simulation model which was then used to predict OS based on BCR to treatment. **Results:** The results show that the extremes of BCR are strong predictors of OS in MM, with patients achieving Complete Remission or Very Good Partial Response having the longest OS and patients with Progressive Disease the shortest OS. However, the discriminatory power of Partial Response versus Minimal Response

versus Stable Disease does not appear to be as strong as the other categories. As expected, predicted OS to all BCR levels decreases with each additional line of therapy. **Conclusions:** Our modelling study suggests that BCR to treatment is able to strongly predict OS in real-world MM clinical practice. Modelling MM in this way will provide clinicians, patients and funders with accurate evidence of the impacts of treatment and policy decisions. Importantly, such modelling could be explored further to facilitate more rapid determinations in regulatory authority drug approval processes so enabling patients earlier access to more effective therapies.

Introduction: Multiple myeloma (MM) is a clonal plasma cell disorder found in the bone marrow that produces a monoclonal immunoglobulin (M-protein). Blood based M-protein diagnostics allows monitoring of disease activity, but with limited sensitivity. Minimal residual disease (MRD) status is a powerful prognostic biomarker. Lack of sensitivity prevents MRD detection by conventional blood based assays. Bone marrow based assays such as next-generation sequencing (NGS) are highly sensitive in measuring MRD. However, bone marrow biopsies introduce a risk of non-representative sampling and are invasive, which limits repeated testing. Frequent MM monitoring during remission could provide actionable information on disease activity and treatment response. Earlier detection of disease progression could lead to early intervention and, potentially, patient survival benefits. The aim of this study was to perform M-protein monitoring on blood samples of MM patients with sensitive targeted mass spectrometry. **Methods:** We have developed a targeted mass spectrometry-based MRD blood-test (MS-MRD) that detects clonotypic peptides originating from the variable region of the M-protein. Absolute M-protein quantification (g/L) was performed based on the M-protein peptide and an internal standard, and the data were evaluated for early increases in disease activity. MS-MRD was performed on 926 longitudinally collected sera of 41 MM patients from the IFM 2009 trial (ClinicalTrials.gov number: NCT01191060). **Results:** Based on unique patient-specific M-protein peptides, absolute M-protein quantification was feasible in all 41 patients with 1000 times higher sensitivity compared to electrophoretic M-protein quantification. For patients with confirmed progression within the serum sample collection period, MS-MRD revealed the increase of MM disease activity on average 455 days earlier than the progression detected with currently used routine diagnostics ($p \leq 0.0001$). **Conclusions:** MS-MRD blood-testing is feasible in all patients with multiple myeloma and it has similar sensitivity and prognostic value compared to NGS-MRD evaluation performed on bone marrow. The MS-MRD blood-test paves the way for dynamic MRD monitoring to allow detection of early disease relapse. This minimally invasive MRD test may proof to be well suited to facilitate future clinical implementation of MRD-guided therapy.

Introduction: Minimal residual disease (MRD) is a sensitive measure of tumor plasma cells in the bone marrow that reflects remission status. The strong prognostic value of MRD negativity which may act as clinically valid surrogate biomarker for progression-free (PFS) and overall survival (OS) in multiple myeloma (MM) has been demonstrated in many clinical trials including meta-analysis (Munshi et al., Blood Advances, 2020). However, large and reliable data with long follow-up from real-world practice are still missing. **Methods:** Newly diagnosed transplant eligible MM patients (pts) who reached at least partial response (PR) on Day +100 (D+100) after autologous stem cell transplantation (ASCT) underwent MRD assessment of the bone marrow using multiparameter flow cytometry (MFC) with sensitivity reaching at least to 10e-5. Patients were treated in the real-world (RW) setting and clinical analysis was performed retrospectively based on data from the Czech Registry of Monoclonal Gammopathies (RMG, https://rmg.healthregistry.org/). Median PFS and OS intervals were calculated since MRD evaluation. **Results:** In total, 342 MM pts treated across

versus Stable Disease does not appear to be as strong as the other categories. As expected, predicted OS to all BCR levels decreases with each additional line of therapy. **Conclusions:** Our modelling study suggests that BCR to treatment is able to strongly predict OS in real-world MM clinical practice. Modelling MM in this way will provide clinicians, patients and funders with accurate evidence of the impacts of treatment and policy decisions. Importantly, such modelling could be explored further to facilitate more rapid determinations in regulatory authority drug approval processes so enabling patients earlier access to more effective therapies.

Introduction: Minimal residual disease (MRD) is a sensitive measure of tumor plasma cells in the bone marrow that reflects remission status. The strong prognostic value of MRD negativity which may act as clinically valid surrogate biomarker for progression-free (PFS) and overall survival (OS) in multiple myeloma (MM) has been demonstrated in many clinical trials including meta-analysis (Munshi et al., Blood Advances, 2020). However, large and reliable data with long follow-up from real-world practice are still missing. **Methods:** Newly diagnosed transplant eligible MM patients (pts) who reached at least partial response (PR) on Day +100 (D+100) after autologous stem cell transplantation (ASCT) underwent MRD assessment of the bone marrow using multiparameter flow cytometry (MFC) with sensitivity reaching at least to 10e-5. Patients were treated in the real-world (RW) setting and clinical analysis was performed retrospectively based on data from the Czech Registry of Monoclonal Gammopathies (RMG, https://rmg.healthregistry.org/). Median PFS and OS intervals were calculated since MRD evaluation. **Results:** In total, 342 MM pts treated across

versus Stable Disease does not appear to be as strong as the other categories. As expected, predicted OS to all BCR levels decreases with each additional line of therapy. **Conclusions:** Our modelling study suggests that BCR to treatment is able to strongly predict OS in real-world MM clinical practice. Modelling MM in this way will provide clinicians, patients and funders with accurate evidence of the impacts of treatment and policy decisions. Importantly, such modelling could be explored further to facilitate more rapid determinations in regulatory authority drug approval processes so enabling patients earlier access to more effective therapies.

Introduction: Multiple myeloma (MM) is a clonal plasma cell disorder found in the bone marrow that produces a monoclonal immunoglobulin (M-protein). Blood based M-protein diagnostics allows monitoring of disease activity, but with limited sensitivity. Minimal residual disease (MRD) status is a powerful prognostic biomarker. Lack of sensitivity prevents MRD detection by conventional blood based assays. Bone marrow based assays such as next-generation sequencing (NGS) are highly sensitive in measuring MRD. However, bone marrow biopsies introduce a risk of non-representative sampling and are invasive, which limits repeated testing. Frequent MM monitoring during remission could provide actionable information on disease activity and treatment response. Earlier detection of disease progression could lead to early intervention and, potentially, patient survival benefits. The aim of this study was to perform M-protein monitoring on blood samples of MM patients with sensitive targeted mass spectrometry. **Methods:** We have developed a targeted mass spectrometry-based MRD blood-test (MS-MRD) that detects clonotypic peptides originating from the variable region of the M-protein. Absolute M-protein quantification (g/L) was performed based on the M-protein peptide and an internal standard, and the data were evaluated for early increases in disease activity. MS-MRD was performed on 926 longitudinally collected sera of 41 MM patients from the IFM 2009 trial (ClinicalTrials.gov number: NCT01191060). **Results:** Based on unique patient-specific M-protein peptides, absolute M-protein quantification was feasible in all 41 patients with 1000 times higher sensitivity compared to electrophoretic M-protein quantification. For patients with confirmed progression within the serum sample collection period, MS-MRD revealed the increase of MM disease activity on average 455 days earlier than the progression detected with currently used routine diagnostics ($p \leq 0.0001$). **Conclusions:** MS-MRD blood-testing is feasible in all patients with multiple myeloma and it has similar sensitivity and prognostic value compared to NGS-MRD evaluation performed on bone marrow. The MS-MRD blood-test paves the way for dynamic MRD monitoring to allow detection of early disease relapse. This minimally invasive MRD test may proof to be well suited to facilitate future clinical implementation of MRD-guided therapy.

Introduction: Minimal residual disease (MRD) is a sensitive measure of tumor plasma cells in the bone marrow that reflects remission status. The strong prognostic value of MRD negativity which may act as clinically valid surrogate biomarker for progression-free (PFS) and overall survival (OS) in multiple myeloma (MM) has been demonstrated in many clinical trials including meta-analysis (Munshi et al., Blood Advances, 2020). However, large and reliable data with long follow-up from real-world practice are still missing. **Methods:** Newly diagnosed transplant eligible MM patients (pts) who reached at least partial response (PR) on Day +100 (D+100) after autologous stem cell transplantation (ASCT) underwent MRD assessment of the bone marrow using multiparameter flow cytometry (MFC) with sensitivity reaching at least to 10e-5. Patients were treated in the real-world (RW) setting and clinical analysis was performed retrospectively based on data from the Czech Registry of Monoclonal Gammopathies (RMG, https://rmg.healthregistry.org/). Median PFS and OS intervals were calculated since MRD evaluation. **Results:** In total, 342 MM pts treated across

6 Czech hematological centers between 2014 and 2022 underwent MRD assessment on D+100 after ASCT using MFC. The most common induction regimen was VTD (bortezomib, thalidomide, dexamethasone) in 70% of pts, the median limit of detection of MFC technique was 0.001%, and the median follow-up was 30.2 months. Overall, 158 (46%) of 342 pts were considered MRD negative which was associated with significantly improved PFS (HR=0.37; 95% CI 0.26 – 0.52; p< 0.001) and OS (HR=0.49; 95% CI 0.3 – 0.81; p=0.004). Median PFS was 49.2 months for pts who were MRD negative vs. 19.0 months for MRD positive pts; median OS was not reached vs. 71.9 months, respectively. In subgroup analysis, MRD negativity was associated with prolonged survival in both high-risk and standard-risk pts by cytogenetics as well as in patients reaching complete remission or better (CR or better) and very good partial response or better (VGPR or better). Finally, in multivariate analysis only MRD positivity and high-risk cytogenetics emerged as independent adverse prognostic factors (HR=2.57; p< 0.001). **Conclusions:** Up to our knowledge, this is the largest real-world study confirming the strong prognostic value of MRD negativity assessed by MFC with median limit of detection to 10e-5 in newly diagnosed transplant-eligible MM. MRD negativity was associated with improved PFS (HR=0.37) and OS (HR=0.49) resembling the results from clinical trials setting. This real-world experience might represent the missing piece of evidence for final approval of MRD as a surrogate for PFS and OS by regulatory authorities.

Introduction: The minimal residual disease (MRD) status is becoming increasingly important as an endpoint for clinical trials in multiple myeloma (MM). For newly diagnosed patients, a strong association between MRD-negativity and long-term survival has been established. However, relapsed MM (RMM) patients often show a short time to next relapse even after having achieved MRD-negativity during salvage therapy. This also holds true for novel immunotherapies, such as bispecific antibodies (BsAb) or CAR-T cells. One explanation could be an increasingly heterogeneous disease distribution with treatment-resistant tumor cells at bone marrow or extramedullary sites other than the iliac crest. We performed a prospective study to address the question if functional imaging complements MRD-diagnostics in RMM patients and at which timepoints residual disease monitoring should be performed. **Methods:** We included 40 patients with at least 2 prior lines of therapy receiving novel agents-based salvage therapy (n=18) or modern immunotherapy (CAR-T or BsAb, n=22). Bone marrow biopsies for MRD detection using the Euroflow-assay (median sensitivity of 3x10-6) and next-generation sequencing (NGS) were taken before initiation of salvage therapy (baseline), and after 3, 6 and 12 months. Whole body MRI including diffusion weighted imaging (DWI) was performed at baseline, and after 1, 3, 6 and 12 months, while 18-F FDG-PET-CT was performed at baseline and after 6 months. **Results:** Here, we present results of an interim analysis at a median follow-up time of 6.4 months (data cutoff May 2023). Notably, at baseline 6 patients (15%) were already Flow-MRD-negative and 5 patients (13%) had very low MRD levels (< 1x10-4). All these patients showed active lesions in both MRI and PET-CT and none of them became MRD-positive during follow-up, demonstrating a highly unbalanced disease distribution. After 3 months, 11/20 patients with at least a VGPR were MRD-negative. Using DWI, active residual lesions were detectable in 4 of the MRD-negative patients (36%). After 6 months, both DWI and PET-CT were applied and the proportion of MRD-negative patients with detectable active lesions increased to 7/11 (64%). PET-CT was more sensitive than DWI in detecting residual disease with 4/7 patients being positive in PET-CT only. Notably, 5/7 patients had received modern immunotherapies, highlighting the prevalence of discrepant findings in this setting. **Conclusions:** Our data suggest that Flow-MRD negativity in RMM patients during salvage therapy needs to be interpreted with caution. The next step will be to test whether NGS can improve the MRD detection rate. Functional imaging also complements MRD-diagnostics after modern immunotherapies. Yet, it remains to be investigated if detected lesions represent active disease or disease remnants and if this combination allows for a better prediction of time to next relapse.

P-077

High sensitivity MRD enumeration using combined size exclusion isolation and immunophenotyping

Sherif Louis[1], Yulia Shifrin[1], Olga Ludkovski[1], Sabine Mai[2]

[1]Telo Genomics Corp.; [2]University of Manitoba

Introduction: Despite the many therapeutic advances in the field of multiple myeloma (MM) that have led to improved outcomes for these patients, MM remains an incurable cancer. Several studies and

most recently, a large scale, pooled analysis of patients from 4 large randomized controlled studies have demonstrated the prognostic utility of attaining minimal residual disease (MRD) negativity with regards to survival. Given the understanding of how heterogeneous the disease is, there is a need to develop technologies that can identify and enumerate MM MRD plasma cells with superior sensitivity, and further characterize the residual clones, thereby profiling them as high, mid or low risk clones. Currently, ongoing trials that are designed to escalate or de-escalate therapy based on MRD status fail to take into consideration the fact that MRD status carries different significance based on the risk profile of any given patient. Several genomic technologies are currently developing MRD assays for post treatment MM patients. These technologies are predominantly focused on MRD detection, and the enumeration of MRD plasma cells. However, each of these technologies, whether in development or in the clinic, has its own technical limitations that prevent the broad applicability of the technology to all MM patients. Furthermore, these technologies are predominantly applicable to bone marrow specimens, which compromise the main utility of MRD, which is to monitor patients repeatedly over time, due to the invasive nature of bone marrow sample collection procedures. **Methods:** We employed a technology for the enumeration of MRD based on the immunostaining of isolated circulating myeloma plasma cells (CTCs) from peripheral blood. The assay deploys a size-based filtration methodology that recovers CTCs from the patient's blood sample. This is followed by immunostaining, fluorescence three-dimensional (3D) microscopy and automated immunophenotyping detection and enumeration of the MRD plasma cells. **Results:** We report our proof of principle results from spiking experiments where blood samples from consented normal donors were spiked with cells from a characterized and commercially available MM cell line. We report a repeatable achieved sensitivity of up to 10-7 and the confirmed repeatable sensitivity of 10-4-10-7 with accuracy of over 85% across all tested detection levels. **Conclusions:** The technology has the potential to provide a simplified rapid assay for MRD detection and enumeration with satisfactory sensitivity beyond assays in development or currently in the clinic. The assay has the advantages of: 1- a quick turnaround time within 48-72 hours, and 2- applicability to the broader spectrum of MM patients. Furthermore, the isolation of the MM MRD cells with such high sensitivity presents a possibility to accurately profile the level of genomic instability in these cells and provide a prognostic assessment based on the level of aggressiveness of the analyzed MRD cells from the individual patient.

Introduction: Measurable Residual Disease (MRD) is rapidly becoming one of the most relevant prognostics indicators for patients with multiple myeloma (MM). The main objective of this cross-sectional, multicenter, non-interventional study was to evaluate the bone marrow MRD status in MM patients in Portugal who had achieved CR and were on their second or third lines of therapy. **Methods:** This study includes relapsed MM (rMM) patients in 2nd or 3rd line of treatment who met the eligibility criteria, including confirmation of the CR defined by negative immunofixation on the serum and urine. Next-Generation Flow (NGF) MRD evaluation of bone marrow aspirate was performed using the standardized 2-tube 8-color EuroFlow approach, with a level of sensitivity of 10^{-5} (0.001%). "Undetectable MRD (uMRD)" was defined as the absence of tumor plasma cells within 100,000 bone marrow cells (10^{-5}). Demographic data, medical history, MM characteristics, treatments and measures of effectiveness were collected, and descriptive statistics were used to summarize data. **Results:** Among the 68 subjects who gave informed consent, 48 were considered eligible for the study, with a median age of 68 (44 to 84 years). Twenty-two (44%) patients had ISS stage III disease, 6 out of 33 patients with available data had a high-risk cytogenetic profile (18.2%) and 7 out of 48 have documented extra-medullary disease (EMD) (14.5%). Of the 48 subjects with confirmed CR, 31 (64.6%) achieved MRD negativity. This incidence was lower in ISS III patients compared with ISS I/II (60% vs. 70.8%, respectively), in patients with high-risk cytogenetics vs. standard risk (33.3% vs. 76%, respectively) and in patients treated without daratumumab-containing regimens compared with those who were treated with daratumumab containing regimens (MRD undetectable in 57.1% and 75%, respectively). The incidence of MRD negativity is higher in daratumumab-containing regimens in

most recently, a large scale, pooled analysis of patients from 4 large randomized controlled studies have demonstrated the prognostic utility of attaining minimal residual disease (MRD) negativity with regards to survival. Given the understanding of how heterogeneous the disease is, there is a need to develop technologies that can identify and enumerate MM MRD plasma cells with superior sensitivity, and further characterize the residual clones, thereby profiling them as high, mid or low risk clones. Currently, ongoing trials that are designed to escalate or de-escalate therapy based on MRD status fail to take into consideration the fact that MRD status carries different significance based on the risk profile of any given patient. Several genomic technologies are currently developing MRD assays for post treatment MM patients. These technologies are predominantly focused on MRD detection, and the enumeration of MRD plasma cells. However, each of these technologies, whether in development or in the clinic, has its own technical limitations that prevent the broad applicability of the technology to all MM patients. Furthermore, these technologies are predominantly applicable to bone marrow specimens, which compromise the main utility of MRD, which is to monitor patients repeatedly over time, due to the invasive nature of bone marrow sample collection procedures. **Methods:** We employed a technology for the enumeration of MRD based on the immunostaining of isolated circulating myeloma plasma cells (CTCs) from peripheral blood. The assay deploys a size-based filtration methodology that recovers CTCs from the patient's blood sample. This is followed by immunostaining, fluorescence three-dimensional (3D) microscopy and automated immunophenotyping detection and enumeration of the MRD plasma cells. **Results:** We report our proof of principle results from spiking experiments where blood samples from consented normal donors were spiked with cells from a characterized and commercially available MM cell line. We report a repeatable achieved sensitivity of up to 10-7 and the confirmed repeatable sensitivity of 10-4-10-7 with accuracy of over 85% across all tested detection levels. **Conclusions:** The technology has the potential to provide a simplified rapid assay for MRD detection and enumeration with satisfactory sensitivity beyond assays in development or currently in the clinic. The assay has the advantages of: 1- a quick turnaround time within 48-72 hours, and 2- applicability to the broader spectrum of MM patients. Furthermore, the isolation of the MM MRD cells with such high sensitivity presents a possibility to accurately profile the level of genomic instability in these cells and provide a prognostic assessment based on the level of aggressiveness of the analyzed MRD cells from the individual patient.

Introduction: Measurable Residual Disease (MRD) is rapidly becoming one of the most relevant prognostics indicators for patients with multiple myeloma (MM). The main objective of this cross-sectional, multicenter, non-interventional study was to evaluate the bone marrow MRD status in MM patients in Portugal who had achieved CR and were on their second or third lines of therapy. **Methods:** This study includes relapsed MM (rMM) patients in 2nd or 3rd line of treatment who met the eligibility criteria, including confirmation of the CR defined by negative immunofixation on the serum and urine. Next-Generation Flow (NGF) MRD evaluation of bone marrow aspirate was performed using the standardized 2-tube 8-color EuroFlow approach, with a level of sensitivity of 10^{-5} (0.001%). "Undetectable MRD (uMRD)" was defined as the absence of tumor plasma cells within 100,000 bone marrow cells (10^{-5}). Demographic data, medical history, MM characteristics, treatments and measures of effectiveness were collected, and descriptive statistics were used to summarize data. **Results:** Among the 68 subjects who gave informed consent, 48 were considered eligible for the study, with a median age of 68 (44 to 84 years). Twenty-two (44%) patients had ISS stage III disease, 6 out of 33 patients with available data had a high-risk cytogenetic profile (18.2%) and 7 out of 48 have documented extra-medullary disease (EMD) (14.5%). Of the 48 subjects with confirmed CR, 31 (64.6%) achieved MRD negativity. This incidence was lower in ISS III patients compared with ISS I/II (60% vs. 70.8%, respectively), in patients with high-risk cytogenetics vs. standard risk (33.3% vs. 76%, respectively) and in patients treated without daratumumab-containing regimens compared with those who were treated with daratumumab containing regimens (MRD undetectable in 57.1% and 75%, respectively). The incidence of MRD negativity is higher in daratumumab-containing regimens in

2nd line of treatment compared to the 3rd line (80% and 60%, respectively). **Conclusions:** With the current treatment protocols it is possible to achieve high quality responses, including uMRD, both in 2nd and 3rd lines of treatment. In our study, better quality of CR response, defined by a higher rate of uMRD, was found in patients treated in 2nd line of treatment, in those patients exposed to daratumumab containing regimens, and in patients with no adverse prognosis factors (defined by ISS III or high-risk cytogenetics). These findings support the relevance of MRD detection in real-world rMM setting. The Euroflow/NGF technique for MRD detection is feasible in clinical practice, enhancing the quality and sensitivity of MM response evaluation. These real-world results endorse the published clinical trials outcomes but further confirmation in larger cohorts is warranted.

Impact of treatment effect on measurable residual disease (MRD) and progression-free survival (PFS): an aggregate data analysis from randomized clinical trials in multiple myeloma (MM)

Bruno Paiva[1], Anastasiia Zherniakova[2], Jorge Nuñez[3], Paula Rodríguez-Otero[4], Qian Shi[5], Nikhil Munshi[6], Brian Durie[7], Jesús San-Miguel[8]

[1]Clínica Universidad de Navarra (CUN), Centro de Investigación Médica Aplicada (CIMA LAB Diagnostics), IDISNA, CIBERONC; [2]Centro de Investigación Médica Aplicada, University of Navarra, Pamplona, Spain; [3]Clinica Universidad de Navarra; [4]Clínica Universidad de Navarra, CIMA, CIBERONC, IDISNA, Pamplona, Spain; [5]Mayo Clinic; [6]Dana-Farber Cancer Institute, Boston, MA, USA, Veterans Affairs Boston Healthcare System/Harvard Medical School; [7]Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, CA; [8]Cancer Center Clinica Universidad de Navarra, Centro Investigacion Medica Aplicada, Instituto de Investigacion de Navarra, Centro Investigacion Biomedica en Red Cancer, Pamplona, Spain

Introduction: Novel regimens are needed to increase cure rates in MM, but new studies will not have a (positive or negative) readout for many years due to the unprecedented PFS and overall survival achieved with current therapies. Assessment of MRD is one of the most relevant prognostic factors and outperforms conventional methods of response assessment in MM. However, the role of MRD as a surrogate of treatment efficacy for potential use as an endpoint in clinical trials, remains uncertain. **Methods:** We soughed to analyze the correlation between MRD negative rates defined according to the IMWG response criteria and PFS benefit in randomized clinical trials. For this purpose, we searched for studies describing PFS and MRD data in more than 50 patients in each treatment arm, using next-generation flow cytometry or next-generation sequencing methods with a reported minimum sensitivity of 10-5 until the 2nd of December 2022. MRD negative rates were calculated for the intent-to-treat population and regardless of the depth of response. The strength of the association between the treatment effect on PFS and the treatment effect on MRD negative rates was quantified with the trial-level coefficient of determination (R2trial) and the 95% confidence interval (95% CI). The analyses were weighted by the trial sample size. The criteria for R2trial interpretation was set a priori as poor (0.8). **Results:** The weighted R2trial observed in the aggregated analysis of the 15 clinical trials was 0.70 (95% CI 0.41 - 0.98). Sensitivity analyses using a leave-one-out approach showed consistent R2trial levels ranging from 0.62 to 0.78. Sub analysis according to the inclusion of an autologous transplant in clinical trials showed a similar weighted R2trial in NDTE (0.74, 95% CI 0.24 – 1.00) and NDTI/RRMM (0.83, 95% CI 0.57 – 1.00). Next, we compared the difference in MRD negative rates between experimental vs control arms in clinical trials demonstrating a reduction in the risk of progression and/or death greater than 40% vs those that did not. The median (p25 - p75) difference in MRD negative rates was significantly higher in clinical trials with a hazard ratio < 0.60 vs ≥ 0.60: 21% (17% - 22%) vs 2.5% (0.75% - 5.4%), respectively (P < .001). Interestingly, there was nearly no overlap between p25 vs p75 difference in MRD negative rates observed in the former vs the later studies. Thus, it appears that a cutoff of approximately 10% difference in MRD negative rates between treatment arms may predict a meaningful improvement in PFS. **Conclusions:** The ongoing meta-analyses based on individual patient-level data is mandatory to determine if MRD is a statistically robust surrogate of treatment efficacy, defined according to PFS benefit (i.e. i2TEAMM). Meanwhile, this study suggests moderate value and could provide guidance on the definition of MRD endpoints in MM.

Introduction: Because the DuraClone has benefits of shorter time and lower cost to generate minimal residual disease (MRD) measurement compared to EuroFlow which is regarded as standard multiparameter flow cytometry (MFC) method, we explored whether the MRD detection by DuraClone method could be reliable for real-world practice for multiple myeloma (MM). **Methods:** We included 166 patients as the cohort of current study based on following inclusion criteria: (i) patients who have available MRD data at 3±2 months post-autologous stem cell transplantation (ASCT) (ii) Patient who received ASCT as a part of the front-line treatment. Fresh EDTA anticoagulated bone marrow aspirate samples were collected from treated patients with MM. Red blood cells were lysed using Versafix solution (VersaLyse supplemented with 0.25% IOTest Fixative Solution, Beckman Coulter) and cell suspensions containing 5×10^6 nucleated cells were transferred to DuraClone RE PC tubes. DuraClone RE PC antibody panel was composed of CD81-FITC, CD27-PE, CD19-PC5.5, CD200-PC7, CD138-APC, CD56-APC-A750, CD38-Pacific Blue, CD45-Krome Orange. **Results:**

Of 166 patients in our study, there were 113 patients (68.1%) showed MRD-negative (MRD- group) while 53 cases (31.9%) presented MRD-positivity (MRD+ group). With median follow-up of 24.4 months from ASCT, MRD+ group showed poorer survival outcomes compared to MRD- group: 24-months progression-free survival (PFS) rate, 50.6 vs. 72.3%, p< 0.001; 24-months cumulative incidence of MM progression, 46.7 vs. 26.7%, p=0.002. The multivariable analysis showed that MRD status at 3 months was significantly associated with both PFS (Hazard ratio= 2.35, p=0.008) and cumulative incidence of MM progression (Hazard ratio=2.45, p=0.004), even after adjustment for other potential factors. Of MRD- group (n=113), we further analyzed with 67 patients who have data of secondarily measured MRD after 1 year from first measurement of MRD. Patients with conversion of MRD to positivity (n = 24) showed significantly lower outcomes compared to patients achieving sustained MRD negativity (n=43): 24 months-PFS rate, 69.7 vs. 91.9%, p=0.01; 24-months cumulative incidence of MM progression, 30.3% vs. 5.7%, p=0.004. Among 53 patients of MRD+ group, A 24 months-PFS rate in patients who received no further treatment (n=11) showed significantly lower compared to that in patients with subsequent therapy (20.5 vs. 59.8%, p=0.019), we also observed a poor trend of 24 months-cumulative incidence of MM progression in patients who received no further treatment rather than in patients with subsequent therapy (69.3 vs. 40.2%, p=0.07) **Conclusions:** Our data revealed that MRD measurement using DuraClone panel could be applicable with a sensitivity of $1/10^5$ which value is the prerequisite by IMWG recommendation. DuraClone panel-used MRD could be a useful approach regarding both prognostic impact and predictive power for MRD-adopted treatment.

P-081

Sensitive detection of M-proteins and FLC in blood for diagnosis and monitoring of multiple myeloma

Rudolf Kupcik[1], Marie Vajrychova[1], Katerina Hrochova[2], Adela Tomasova[3], Jakub Radocha[4]

[1]Biomedical Research Centre, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic; [2]The Fingerland Department of Pathology, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic; [3]Institute of Clinical Biochemistry and Diagnostics, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic; [4]4th Department of Internal Medicine – Hematology, University Hospital Hradec Kralove, Charles University, Faculty of Medicine in Hradec Králové, Hradec Kralove, Czech Republic

Introduction: Multiple myeloma (MM) is a cancer of plasma cells (myeloma cells) that accumulate in the bone marrow and produce abnormal monoclonal immunoglobulins (mAb, M-proteins). Despite the development of new therapies, MM is still associated with a high likelihood of persistent minimal residual disease (MRD) and thus earlier relapse. Relapse in MM is caused by clonal heterogeneity and evolution, which can lead to selection of drug-resistant malignant plasma cell (PC) clone(s), contributing to treatment failure. Detection of persistent clones, after treatment, is currently limited due to the invasiveness of bone marrow biopsy and the very low frequency of sampling. Therefore, the main goal of our work was to develop a method for sensitive detection of low-abundant PC clones based on the detection of M-proteins and free light chains (FLC) in human serum. **Methods:** The newly developed method combines selective affinity isolation of M-proteins and FLC from a blood sample and their sensitive analysis by high-performance liquid chromatography with UV detection (af-HPLC/UV). Af-HPLC/UV also served as the first step for targeted detection of the variable region (CDR3) of M-proteins by high-resolution mass spectrometry after prior sequencing of the corresponding DNA regions. The reliability and sensitivity of the method were tested on three types of mAb standards added to human sera. Patient samples before and after treatment were also included in this study. **Results:** The af-HPLC/UV workflow was able to detect mAb in serum with high sensitivity (≤100 mg.Le-1). Selective isolation of M-protein and FLC allowed quantitative separation of mAbs by light chain types, which has great potential for the diagnosis of oligoclonality. HPLC with UV detection is then suitable for accurate LC and partial HC classification, as well as for the determination of therapeutic mAbs, which usually complicate analysis by immunofixation electrophoresis. In addition, the sensitivity of the entire workflow can be greatly enhanced when combined with LC-MS/MS of the CDR3 region, which is unique to each antibody clone. These regions can then be monitored in a targeted manner by mass spectrometry based on initial analysis of myeloma cell DNA. The combination of very high sensitivity and the ability to detect multiple clones thus has the potential to sensitively detect resistant and emerging myeloma cell clones in MRD based on M-proteins and FLCs detection directly in the blood. **Conclusions:** With these new MM detection methods, it may be possible in the future to carefully monitor patients at short time intervals and detect not only clones from the time of diagnosis, but also newly formed clones with high sensitivity from blood. The method then has the potential to replace invasive and often problematic bone marrow aspiration.

[1]Oslo University Hospital; [2]Stavanger Hospital; [3]Vestfold Hospital; [4]Haukeland University Hospital; [5]UNN Tromsø; [6]Kalnes Hospital; [7]Levanger Hospital; [8]Sørlandet Hospital; [9]Ålesund Hospital; [10]Vilnius University Hospital; [11]Bodø Hospital; [12]St.Olavs Hospital; [13]Oslo Myeloma Center, Oslo University Hospital, Oslo, Norway, and KG Jebsen Center for B Cell Malignancies, University of Oslo, Oslo, Norway

Of 166 patients in our study, there were 113 patients (68.1%) showed MRD-negative (MRD- group) while 53 cases (31.9%) presented MRD-positivity (MRD+ group). With median follow-up of 24.4 months from ASCT, MRD+ group showed poorer survival outcomes compared to MRD- group: 24-months progression-free survival (PFS) rate, 50.6 vs. 72.3%, p< 0.001; 24-months cumulative incidence of MM progression, 46.7 vs. 26.7%, p=0.002. The multivariable analysis showed that MRD status at 3 months was significantly associated with both PFS (Hazard ratio= 2.35, p=0.008) and cumulative incidence of MM progression (Hazard ratio=2.45, p=0.004), even after adjustment for other potential factors. Of MRD- group (n=113), we further analyzed with 67 patients who have data of secondarily measured MRD after 1 year from first measurement of MRD. Patients with conversion of MRD to positivity (n = 24) showed significantly lower outcomes compared to patients achieving sustained MRD negativity (n=43): 24 months-PFS rate, 69.7 vs. 91.9%, p=0.01; 24-months cumulative incidence of MM progression, 30.3% vs. 5.7%, p=0.004. Among 53 patients of MRD+ group, A 24 months-PFS rate in patients who received no further treatment (n=11) showed significantly lower compared to that in patients with subsequent therapy (20.5 vs. 59.8%, p=0.019), we also observed a poor trend of 24 months-cumulative incidence of MM progression in patients who received no further treatment rather than in patients with subsequent therapy (69.3 vs. 40.2%, p=0.07) **Conclusions:** Our data revealed that MRD measurement using DuraClone panel could be applicable with a sensitivity of $1/10^5$ which value is the prerequisite by IMWG recommendation. DuraClone panel-used MRD could be a useful approach regarding both prognostic impact and predictive power for MRD-adopted treatment.

Introduction: Multiple myeloma (MM) is a cancer of plasma cells (myeloma cells) that accumulate in the bone marrow and produce abnormal monoclonal immunoglobulins (mAb, M-proteins). Despite the development of new therapies, MM is still associated with a high likelihood of persistent minimal residual disease (MRD) and thus earlier relapse. Relapse in MM is caused by clonal heterogeneity and evolution, which can lead to selection of drug-resistant malignant plasma cell (PC) clone(s), contributing to treatment failure. Detection of persistent clones, after treatment, is currently limited due to the invasiveness of bone marrow biopsy and the very low frequency of sampling. Therefore, the main goal of our work was to develop a method for sensitive detection of low-abundant PC clones based on the detection of M-proteins and free light chains (FLC) in human serum. **Methods:** The newly developed method combines selective affinity isolation of M-proteins and FLC from a blood sample and their sensitive analysis by high-performance liquid chromatography with UV detection (af-HPLC/UV). Af-HPLC/UV also served as the first step for targeted detection of the variable region (CDR3) of M-proteins by high-resolution mass spectrometry after prior sequencing of the corresponding DNA regions. The reliability and sensitivity of the method were tested on three types of mAb standards added to human sera. Patient samples before and after treatment were also included in this study. **Results:** The af-HPLC/UV workflow was able to detect mAb in serum with high sensitivity (≤100 mg.Le-1). Selective isolation of M-protein and FLC allowed quantitative separation of mAbs by light chain types, which has great potential for the diagnosis of oligoclonality. HPLC with UV detection is then suitable for accurate LC and partial HC classification, as well as for the determination of therapeutic mAbs, which usually complicate analysis by immunofixation electrophoresis. In addition, the sensitivity of the entire workflow can be greatly enhanced when combined with LC-MS/MS of the CDR3 region, which is unique to each antibody clone. These regions can then be monitored in a targeted manner by mass spectrometry based on initial analysis of myeloma cell DNA. The combination of very high sensitivity and the ability to detect multiple clones thus has the potential to sensitively detect resistant and emerging myeloma cell clones in MRD based on M-proteins and FLCs detection directly in the blood. **Conclusions:** With these new MM detection methods, it may be possible in the future to carefully monitor patients at short time intervals and detect not only clones from the time of diagnosis, but also newly formed clones with high sensitivity from blood. The method then has the potential to replace invasive and often problematic bone marrow aspiration.

Introduction: Although many new treatment options have become available, multiple myeloma (MM) is still considered an incurable disease. More recently, the role of achieving minimal residual disease (MRD) negativity has become more clearly defined in patients with MM. Multiple studies show that bone marrow based MRD assessment is one of the strongest prognostic factors, and deeper responses correlate with more favorable outcomes. The REMNANT study will evaluate if treating at MRD relapse after 1st line (1.L) therapy prolongs PFS and OS compared to starting treatment at biochemical relapse/progressive disease (PD) in MM patients **Methods:** The REMNANT study (RElapse from Mrd Negativity As iNdication for Treatment) is an academic, multicenter, open-label, randomized phase II/III study of newly diagnosed (ND) MM patients eligible for autologous stem cell transplant (ASCT). The study has a population-based approach and few exclusion criteria apply, including patients with kidney failure, amyloidosis and other comorbidities. 391 NDMM patients (age 18-75 years) eligible for ASCT will be enrolled in the study and receive 1.L treatment according to Norwegian national guidelines; 4 pre-transplant induction and 4 post-transplant consolidation cycles of bortezomib, lenalidomide and dexamethasone (VRd). After induction patients will undergo tandem or single transplant, depending on toxicity and response to first transplant. Following 1.L treatment 176 patients who are >CR and MRD negative (NGF Euroflow) will be enrolled in part 2 of the study and will be randomized in a 1:1 ratio to receive second line treatment (2.L) at MRD relapse in arm A or at PD in arm B. At loss of MRD negativity (arm A) or at PD in arm B, second line treatment will be daratumumab, carfilzomib, and dexamethasone and patients will be followed for PFS and OS. In part 2 we will compare different methods for measuring MRD; NGF, NGS, mass spectrometry and PET-CT. We want to evaluate how the different methods compare when it comes to sensitivity and outcome (PFS and OS) **Results:** As of May 1st 2023, 276 patients have been enrolled in part 1. 128 patients had reached the post-consolidation step and have been evaluated for MRD status and 66 (52%) were >CR and MRD negative and have been enrolled in part 2 of the study. ORR was 97%. Fifty-two of 276 (17.6%) patients have discontinued treatment during 1.L; 22 due to PD, 11 patients have withdrawn from the study, 6 have died and 5 discontinued due to adverse event. Fifty-two of 276 (17.6%) patients have discontinued treatment during 1.L; 22 due to PD, 11 patients have withdrawn from the study, 6 have died and 5 discontinued due to adverse event. Among patients with PD during 1.L treatment 59% had high-risk cytogenetics (with gain1q and/or del17p and/or t(4;14)). A total of 8 patients have started 2nd line treatment in part 2 due to loss of MRD or PD. **Conclusions:** Data so far show a very good response rate of 97%. The MRD negativity rate among patients who have finished 1.L treatment was 52%.

The role of minimal residual disease evaluation for patients with multiple myeloma

Yoon Sang Eun[1], Hyun-Young Kim[2], Duck Cho[2], Seok Jin Kim[1], Kihyun Kim[3]

[1]Division of Hematology/Oncology, Department of Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea; [2]Samsung Medical CenterDepartment of Laboratory Medicine and Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; [3]Sungkyunkwan University Samsung Medical Center, Seoul, South Korea

Introduction: A new treatment goal for multiple myeloma (MM) is the achievement of minimal residual disease (MRD) negativity, indicating a profound response to therapy. In this study, we present the findings of MRD assessment conducted over three years at our institute, shedding light on its role in managing newly diagnosed (NDMM) or relapsed/refractory MM (RRMM). **Methods:** Since 2019, the institute has initiated a minimal residual disease (MRD) evaluation using next-generation flow (NGF) technology. A minimum of 10^7 cells per sample were acquired to ensure high sensitivity. In addition, the detection limit was set at 20 cells among the total nucleated cells, enabling a sensitivity of 10^5 or higher for all samples. The initial MRD assessment (MRD1) was performed upon achieving VGPR or CR. Subsequently, the second MRD assessment (MRD2) was conducted 12 months after the initial assessment. The progression-free survival 1 (PFS1) was defined from the initiation of front-line chemotherapy until disease progression, death from any cause, or the last follow-up. The PFS2 was determined from the start of second-line chemotherapy. The overall survival (OS) was defined as the period from the commencement of front-line chemotherapy until death or the last follow-up. Statistical analyses were conducted using the IBM PASW version 25.0. **Results:** MRD1 was evaluated in 138 NDMM and 60 RRMM, followed by MRD2 in 53 NDMM and 27 RRMM. The NDMM patients with MRD1-negative seemed to show superior median PFS1 to those without MRD1-negative (67.9 vs. 34.3 months, P=0.123). Although the difference was not statistically significant, patients with MRD2-negative results tended to exhibit a slightly better median PFS1 in a Kaplan-Myer graph than those without MRD2-negative results (not reached vs. not reached, P=0.258). Furthermore, the patients who achieved sustained MRD-negative or converted from MRD1-positive to MRD2-negative seemed to present better PFS than those who did not achieve final MRD2-negative (P=0.337). OS seemed superior in patients with MRD1-negative (P=0.069) but not MRD2-negative (P=0.910). PFS2 between RRMM with MRD1-negative and MRD1-positive was not statistically different (46.0 vs. 34.9 months, P=0.169). Moreover, the patients with MRD2-negative seemed somewhat to present longer median PFS2 than those with MRD2-positive (NR vs. 35.1 months, P=0.058), but not statistically. Moreover, the RRMM patients with sequential MRD-negative or converted from MRD1-positive to MRD2-negative did not show differences in PFS2 compared to other groups (P=0.185). **Conclusions:** We discussed the significance of MRD in the context of both NDMM and RRMM. While the results did not fully demonstrate the critical impact of the sequential acquisition of MRD-negativity following MRD1 due to the small number of patients in each group and short-term follow-up duration, it appeared that patients who maintained MRD-negativity had a notable survival advantage compared to those who tested positive for MRD1 or MRD2 at least once.

Use of peripheral blood for MRD assessment during maintenance therapy: UTSW experience

Aishwarya Sannareddy[1], Heidi Simmons[2], Ankit Kansagra[3], Adeel Khan[4], Aimaz Afrough[4], Larry Anderson[4], Gurbakhash Kaur[4]

[1]UT Southwestern Medical Center; [2]Adaptive Biotechnologies; [3]The Janssen Pharmaceutical Companies of Johnson & Johnson; [4]Cellular Therapy and Hematologic Malignancies Program, Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX, USA

Introduction: Over the years, the treatment modalities for patients diagnosed with Multiple Myeloma (MM) have improved and evolved. Lasting responses and increase in survival outcomes to newer therapies have led to development of advanced tools used to assess the disease pattern. Minimal residual disease (MRD) test is one such tool which detects cancer cells in remission and identifies increasing numbers of tumor cells. This increase in the number of tumor cells may lead to relapse, with a potential to inform clinical decisions on therapy intensification or de-escalation. Bone marrow (BM) biopsies are ideal for MRD assessment in MM patients. There is interest in peripheral blood (PB) use for assessment, which is less invasive, allowing frequent monitoring. In our real-world data set, we studied PB MRD use in patients who were MRD tested by the clonoSEQ® assay (Adaptive Biotechnologies). **Methods:** We performed a retrospective analysis on 49 MM patients with MRD monitored by clonoSEQ at UT Southwestern Medical Center, Dallas, TX. We collected data on demographics; oncology history, treatment history, MRD test and responses. All patients had a initial assessment with BM samples. **Results:** 49 patients underwent both BM and PB MRD at different time points. Analysis of PB MRD use revealed 30 patients tested during maintenance therapy post melphalan autologous stem cell transplant (SCT) and 19 patients who had relapse post SCT. MRD positive(+)PB was concurrent with or preceded clinical relapse in 3 patients. These patients were monitored with MRD in PB between regular BM monitoring. The 1st patient was 1 year post-SCT on Revlimid maintenance with normal light chains, met the criteria for relapse within six months of + PB MRD test. The 2nd patient, 19 months post-SCT on Revlimid maintenance, had elevated Kappa Light chains of 173.30mg/L at the time of the PB MRD test and met the definition of disease relapse, prompting a change in treatment, as the PB MRD results were consistent with the elevated kappa light chains. The 3rd patient, 11 months post-SCT on maintenance therapy, initially had normal light chains at the time of the PB MRD test. However, within a month, their kappa light chains became elevated, indicative of relapsed disease and requiring a change in treatment. All 3 patients had high plasma cell burden (>50%) and high-risk cytogenetics at diagnosis. They all had ≥ 3 lines of chemotherapy and underwent SCT within 19 months from diagnosis. 2 out of 3 patients passed within 2 years of SCT. **Conclusions:** From our small retrospective data analysis, we found evidence that PB MRD monitoring may be informative in certain clinical scenarios such as between BM MRDs during maintenance therapy. MRD+ PB results were concordant or preceded detection of rising disease burden by other clinical measurements. The assessments of MRD in the PB may allow tracking disease in certain clinical settings. Further research with larger patient cohorts is needed to define the utility of PB MRD monitoring in MM patients.

Introduction: Given the invasive nature of bone marrow sampling, there is growing interest in blood-based methods of measurable residual disease (MRD) testing for patients with multiple myeloma (MM). We previously reported data utilizing clonotypic mass spectrometry (MS) in patients with intact immunoglobulin M-protein (Slade, ASH 2022). However, 10-20% of patients present with light chain (LC) M-protein and data on the feasibility of clonotypic MS in these patients is limited. **Methods:** Given the invasive nature of bone marrow sampling, there is growing interest in blood-based methods of measurable residual disease (MRD) testing for patients with multiple myeloma (MM). We previously reported data utilizing clonotypic mass spectrometry (MS) in patients with intact immunoglobulin M-protein (Slade, ASH 2022). However, 10-20% of patients present with light chain (LC) M-protein and data on the feasibility of clonotypic MS in these patients is limited. **Results:** Of 17 patients analyzed, 15 had a measurable clonotypic signature at diagnosis while 2 did not and were excluded from further analysis. Fourteen patients were White and 8 were male. Three, 8 and 4 patients were R-ISS stage I, II and III. The median age at AHCT was 59 (range: 45 – 76). The median difference in FLC (dFLC) at diagnosis was 265 mg/dL (range: 43 – 1449) and median EasyM was 5.62 arbitrary units (AU) (range 0.16 – 207.86). The lower limit of quantification varied given the unique clonotypic signature of each M-protein, with a median of 0.0088 AU (range: 0.00094 – 0.033) and median % quantifiable reduction in EasyM of 99.87% (range: 95.86 – 99.99%). At day +100, 14 patients (93%) were in CR. One was in VGPR at day +100. The median dFLC was 0.10 mg/dL (range 0.00 – 0.99). 8 (53%) had no detectable disease by EasyM (MRD-) at day +100; 7 (47%) had residual disease (MRD+). The median % residual EasyM in MRD+ patients was 0.20% of baseline (range 0.02 – 1.12%). Median baseline dFLC (249 vs. 270 mg/dL) and EasyM (0.78 vs. 10.32 AU) were numerically lower in the MRD- group, though these differences did not reach statistical significance. Median follow up was 4.4 years. At last follow up, 4 of 7 patients in the MRD+ group had relapsed and 3 had died. One MRD- patient died in remission from infection on day +619. The remainder of the MRD- patients remain alive and disease-free at a median of 3.9 years (range: 1.0 – 8.3) post-AHCT. **Conclusions:** In

Use of peripheral blood for MRD assessment during maintenance therapy: UTSW experience

Aishwarya Sannareddy[1], Heidi Simmons[2], Ankit Kansagra[3], Adeel Khan[4], Aimaz Afrough[4], Larry Anderson[4], Gurbakhash Kaur[4]

[1]UT Southwestern Medical Center; [2]Adaptive Biotechnologies; [3]The Janssen Pharmaceutical Companies of Johnson & Johnson; [4]Cellular Therapy and Hematologic Malignancies Program, Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX, USA

Introduction: Over the years, the treatment modalities for patients diagnosed with Multiple Myeloma (MM) have improved and evolved. Lasting responses and increase in survival outcomes to newer therapies have led to development of advanced tools used to assess the disease pattern. Minimal residual disease (MRD) test is one such tool which detects cancer cells in remission and identifies increasing numbers of tumor cells. This increase in the number of tumor cells may lead to relapse, with a potential to inform clinical decisions on therapy intensification or de-escalation. Bone marrow (BM) biopsies are ideal for MRD assessment in MM patients. There is interest in peripheral blood (PB) use for assessment, which is less invasive, allowing frequent monitoring. In our real-world data set, we studied PB MRD use in patients who were MRD tested by the clonoSEQ® assay (Adaptive Biotechnologies). **Methods:** We performed a retrospective analysis on 49 MM patients with MRD monitored by clonoSEQ at UT Southwestern Medical Center, Dallas, TX. We collected data on demographics; oncology history, treatment history, MRD test and responses. All patients had a initial assessment with BM samples. **Results:** 49 patients underwent both BM and PB MRD at different time points. Analysis of PB MRD use revealed 30 patients tested during maintenance therapy post melphalan autologous stem cell transplant (SCT) and 19 patients who had relapse post SCT. MRD positive(+)PB was concurrent with or preceded clinical relapse in 3 patients. These patients were monitored with MRD in PB between regular BM monitoring. The 1st patient was 1 year post-SCT on Revlimid maintenance with normal light chains, met the criteria for relapse within six months of + PB MRD test. The 2nd patient, 19 months post-SCT on Revlimid maintenance, had elevated Kappa Light chains of 173.30mg/L at the time of the PB MRD test and met the definition of disease relapse, prompting a change in treatment, as the PB MRD results were consistent with the elevated kappa light chains. The 3rd patient, 11 months post-SCT on maintenance therapy, initially had normal light chains at the time of the PB MRD test. However, within a month, their kappa light chains became elevated, indicative of relapsed disease and requiring a change in treatment. All 3 patients had high plasma cell burden (>50%) and high-risk cytogenetics at diagnosis. They all had ≥ 3 lines of chemotherapy and underwent SCT within 19 months from diagnosis. 2 out of 3 patients passed within 2 years of SCT. **Conclusions:** From our small retrospective data analysis, we found evidence that PB MRD monitoring may be informative in certain clinical scenarios such as between BM MRDs during maintenance therapy. MRD+ PB results were concordant or preceded detection of rising disease burden by other clinical measurements. The assessments of MRD in the PB may allow tracking disease in certain clinical settings. Further research with larger patient cohorts is needed to define the utility of PB MRD monitoring in MM patients.

Patient and haematologist perspectives of minimal residual disease testing in myeloma

Silene ten Seldam[1], Kate Morgan[1], Katie Joyner[1]

[1]Myeloma Patients Europe

Introduction: Minimal residual disease (MRD) refers to a very small number of cancer cells that remain in the body during or after treatment. Despite growing interest of MRD in clinical practice and clinical trials, little is known regarding the perspectives and experiences of MRD testing from haematologists and myeloma patients. This project captured these perspectives on the current and potential future use of MRD in clinical practice and the psychosocial impact of MRD testing on patients and families. **Methods:** Participants were recruited from across Europe through patient organisations, website and via email. Two focus groups with myeloma patients were held along with individual interviews with haematologists. Focus groups and interviews were online and conducted using semi-structured topic guides, informed by a review of existing literature. Discussions were recorded, transcribed, and thematically analysed. **Results:** The focus group discussions with patients (n=14, from 9 countries) included 3 key themes; awareness of MRD, MRD-informed treatment decision making, and the potential psychosocial burden. Awareness of MRD testing varied amongst patients with some unfamiliar and some having experienced MRD testing themselves. Patients felt optimistic about MRD testing, particularly if it can be used for treatment decision making. Patients expressed willingness to consider more frequent bone marrow tests if MRD results could be used as an indicator for maintenance therapy to be stopped. However, they also highlighted the potential emotional and physical burden of attending hospital for the MRD tests, the invasive biopsies required, and the discomfort of waiting for the results. It was also emphasised that a positive MRD result, in the context of no available further treatments, would be particularly hard for patients. The interviews with haematologists (n=9, from 8 countries) included themes on MRD-informed treatment decision making, and MRD implementation considerations. Haematologists were equally optimistic about the potential for MRD testing in clinical practice and its role in guiding treatment decisions such as maintenance treatment plans. However, they also highlighted multiple challenges in implementing MRD testing in clinical practice, such as laboratory capacity and capability issues, the cost and staff training. **Conclusions:** This research highlighted that patients may be unaware of MRD testing, and there is a need for resources for patients and families to facilitate understanding about what it is and the implications of results. Implementation of MRD testing in future clinical practice would also require training and resources for healthcare professionals and laboratory staff to ensure accuracy and consistency across testing centres. The emotional and physical impact of MRD testing on patients will also need to be considered and healthcare providers need to be mindful of this in their communication and care of myeloma patients.

Characterization of minimal residual disease (MRD) in patients with relapsed/refractory multiple myeloma treated with elranatamab: analysis of MagnetisMM-3

Cyrille Touzeau[1], Katja Weisel[2], Nizar Bahlis[3], Hang Quach[4], Finn Hamilton[5], Shen-wu Wang[5], Eric Leip[5], Andrea Viqueira[6], Thomas O'Brien[5], Paula Rodríguez-Otero[7]

[1]CHU de Nantes; [2]Universitäres Cancer Center Hamburg; [3]Arnie Charbonneau Cancer Institute, University of Calgary; [4]Vincent's Hospital Melbourne, University of Melbourne, VIC, Australia; [5]Pfizer Inc; [6]Pfizer SLU, Madrid, Spain; [7]Clínica Universidad de Navarra, CIMA, CIBERONC, IDISNA, Pamplona, Spain

Introduction: MagnetisMM-3 (NCT04649359) is an open-label, multicenter, non-randomized, phase 2 study of elranatamab monotherapy in patients (pts) with multiple myeloma refractory to at least one proteasome inhibitor, one immunomodulatory drug and one anti-CD38 antibody. Achieving MRD negativity has been associated with improved outcomes (PFS, OS). However, successful identification of a baseline diagnostic clone in all relapsed refractory patients remains a challenge. This is the first characterization of baseline calibration success and MRD assessment in pts naïve to B-cell maturation antigen (BCMA)-directed therapy (Cohort A) from MagnetisMM-3. **Methods:** An index/calibration bone marrow aspirate (BMA) was required at screening to identify the dominant rearranged B-cell receptor sequence(s) used to track MRD status during treatment. While a freshly collected BMA sample was preferred to identify the dominant clone, other sample types were permitted and submitted for testing. MRD tracking was performed with BMA samples collected at suspected CR/sCR and after 6 months, 12 months, and yearly after achieving CR. MRD negative status was defined as having a CR or sCR and having less than 1 malignant plasma cell in 10^{-5} nucleated cells as assessed by the clonoSEQ assay. Bulk RNA-seq analysis was performed using BMA samples collected at screening. Clinical data cutoff was March 2023 (~15 months after last patient initial dose) with a median follow up of 14.7 months. **Results:** Successful identification of the dominant clone at baseline for the purpose of NGS MRD assessment was primarily associated with a higher % BM plasma cell content. In all BCMA naïve patients the CR/sCR and MRD negative rate at a sensitivity of 10^{-5} was 21.1% (n=26/123), and in evaluable patients (CR/sCR with an identified clone at baseline and an on-treatment MRD assessment) the MRD-negative rate was 89.7% (n=26/29). MRD-negativity was achieved across subgroups, however, as expected poor prognosis subgroups such as R-ISS 3, high-risk cytogenetics, presence of EMD or patients with penta-refractory disease achieved a lower MRD-negativity rate. Patients

this study, we showed that EasyM generates a trackable clonotype in the vast majority (88%) of patients with LC MM and that relapse was numerically higher in patients with normal dFLC and MRD+ by EasyM at day +100 after AHCT. MRD-negativity was achieved across subgroups, however, as expected poor prognosis subgroups such as R-ISS 3, high-risk cytogenetics, presence of EMD or patients with penta-refractory disease achieved a lower MRD-negativity rate. Patients

achieving CR/sCR and MRD-negativity had a longer PFS versus all other patients (median PFS not reached by 15 months [95% CI: NE, NE] for pts with CR/sCR and MRD negative vs median PFS of 8.5 months [95%, CI: 3.6, NE] for ≤VGPR or MRD positive). Gene expression analysis of baseline BMA samples was carried out to identify underlying differences between patients that achieved MRD-negativity compared to patients that did not. These results and updated analyses including sustained MRD negativity will be presented. **Conclusions:** MRD-negativity was achieved in 89.7% of evaluable patients. Consistent with available evidence, initial results confirmed better long-term outcomes in MRD-negative patients.

High throughput MGUS monitoring program to support incidental MGUS (iMGUS) detection in the community

Gaurav Agarwal[1], Lauren Campbell[2], Oluremi Carty[2], Sally Moore[3], Sarah Gooding[4], Jaimal Kothari[2], Julia Evans[2], Jemma Larham[2], Lisa Ferguson[2], Pamela Roberts[2], Ross Sadler[2], Karthik Ramasamy[2]

[1]Medical Sciences Division, University of Oxford, Oxford, UK; [2]Oxford University Hospitals NHS Foundation Trust, Oxford, UK; [3]Bath Royal United Hospitals, Bath, UK; [4]MRC Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, UK

Introduction: Monoclonal gammopathy of undetermined significance (MGUS) is present in 1-2% of adults older than 50 years. As 1% of patients progress to multiple myeloma (MM) per year, MGUS monitoring has the potential to improve MM outcomes through earlier diagnosis. A variety of monitoring systems have been implemented in the NHS, including hospital, primary care, and nurse-led surveillance. However, most services are inefficient and unsustainable to support population-based monitoring. Here, we setup a risk-adapted monitoring system (OxCOM), in which patients with new incidental MGUS (iMGUS) in Thames Valley were stratified and prospectively monitored. **Methods:** Patients with a new iMGUS were captured over a 24-month period (between 4th March 2021 and 3rd March 2023) in an Immunology Laboratory covering a population of 2.5 million people. Patients were risk-stratified daily by an attending immunologist into high-risk [IgG >30g/L or IgA/IgM >10g/L; or free light chain (FLC) ratio outside 0.1-7.0; or CRAB criteria], intermediate-risk [IgG 15-30g/L or IgA/IgM 5-10g/L; or FLC ratio outside 0.3-3.0; or monoclonal IgD/E or FLC; or band present in urine] or low-risk MGUS [IgG < 15g/L or IgA/IgM < 5g/L]. Low-risk patients were advised for 4-12-monthly remote blood monitoring, run by an OxCOM administrator. Intermediate-risk patients were advised for routine review in a non-Consultant-led telephone or face-to-face (F2F) clinic (primarily nurse-led, supported by physician associate or haematology trainee). High-risk patients were advised for urgent F2F review by a Consultant Haematologist. **Results:** 1,507 patients had new iMGUS detected over a 24-month period [1,014 low-risk, 290 intermediate-risk and 203 high-risk iMGUS), with median age 76.8 years and median 17 months of follow-up. Of 525 low-risk patients with ≥12-months follow-up, 475 (90%) had attended a further monitoring event. Of 88 intermediate-risk patients attending non-Consultant-led review (56 telephone and 32 F2F), 34 (39%) received further imaging and 10 (11%) had bone marrow biopsy. At last follow-up, 17 (19%) intermediate-risk patients had been moved to OxCOM remote monitoring, 65% had ongoing follow-up and 10 (11%) had been diagnosed with malignancy [2 MM, 3 smouldering MM, 2 Waldenström macroglobulinemia (WM), 2 lymphoma and 1 AL amyloidosis). Of 63 high-risk patients attending urgent Consultant-led F2F review, 41 (65%) had been diagnosed with malignancy (17 MM, 9 smouldering MM, 1 plasmacytoma, 9 WM, 2 lymphoma and 3 AL amyloidosis). **Conclusions:** We demonstrate the feasibility of a risk-adapted high-throughput clinical monitoring service for iMGUS. Immunology Laboratory led central oversight by stratifying patients to either OxCOM remote monitoring, routine OxCOM assessment or urgent F2F haematology review. The service therefore establishes a model to enable tailored follow-up and monitoring of iMGUS, which distributes healthcare resource towards higher-risk patients, whilst enabling sustainable monitoring for lower-risk patients.

[1]Mount Sinai Morningside-West; [2]Memorial Sloan Kettering Cancer Center, New York, NY, USA; [3]Myeloma Service, Sylvester Comprehensive Cancer Center, University of Miami

Introduction: Smoldering multiple myeloma (SMM) is a heterogeneous condition comprised of patients with varying risk of progression to multiple myeloma (MM). Existing models to predict the risk of progression to active disease are based on MM markers from a single time point at initial presentation without regard to marker evolution over time. In this study, we assessed the effect of dynamic temporal changes in the free light chain ratio (FLCr) on the risk of progression from SMM to MM. **Methods:** We performed a retrospective analysis of patients diagnosed with SMM between 2002 and 2019 at Memorial Sloan Kettering Cancer Center with follow-up to 2022. Only patients with available FLCs (Freelite, The Binding Site) at diagnosis were included. Baseline laboratory, pathology, and imaging data, as well as date of diagnosis and progression, were manually reviewed. Progression from SMM to active MM was defined according to the diagnostic criteria at the time of progression or initiating treatment for active MM. Serial FLC levels between the date of diagnosis and progression were obtained by computerized extraction. We assessed the time to progression (TTP) using the Kaplan-Meier method, with log-rank tests for comparison between groups. We used Cox regression to estimate the

achieving CR/sCR and MRD-negativity had a longer PFS versus all other patients (median PFS not reached by 15 months [95% CI: NE, NE] for pts with CR/sCR and MRD negative vs median PFS of 8.5 months [95%, CI: 3.6, NE] for ≤VGPR or MRD positive). Gene expression analysis of baseline BMA samples was carried out to identify underlying differences between patients that achieved MRD-negativity compared to patients that did not. These results and updated analyses including sustained MRD negativity will be presented. **Conclusions:** MRD-negativity was achieved in 89.7% of evaluable patients. Consistent with available evidence, initial results confirmed better long-term outcomes in MRD-negative patients.

Introduction: Monoclonal gammopathy of undetermined significance (MGUS) is present in 1-2% of adults older than 50 years. As 1% of patients progress to multiple myeloma (MM) per year, MGUS monitoring has the potential to improve MM outcomes through earlier diagnosis. A variety of monitoring systems have been implemented in the NHS, including hospital, primary care, and nurse-led surveillance. However, most services are inefficient and unsustainable to support population-based monitoring. Here, we setup a risk-adapted monitoring system (OxCOM), in which patients with new incidental MGUS (iMGUS) in Thames Valley were stratified and prospectively monitored. **Methods:** Patients with a new iMGUS were captured over a 24-month period (between 4th March 2021 and 3rd March 2023) in an Immunology Laboratory covering a population of 2.5 million people. Patients were risk-stratified daily by an attending immunologist into high-risk [IgG >30g/L or IgA/IgM >10g/L; or free light chain (FLC) ratio outside 0.1-7.0; or CRAB criteria], intermediate-risk [IgG 15-30g/L or IgA/IgM 5-10g/L; or FLC ratio outside 0.3-3.0; or monoclonal IgD/E or FLC; or band present in urine] or low-risk MGUS [IgG < 15g/L or IgA/IgM < 5g/L]. Low-risk patients were advised for 4-12-monthly remote blood monitoring, run by an OxCOM administrator. Intermediate-risk patients were advised for routine review in a non-Consultant-led telephone or face-to-face (F2F) clinic (primarily nurse-led, supported by physician associate or haematology trainee). High-risk patients were advised for urgent F2F review by a Consultant Haematologist. **Results:** 1,507 patients had new iMGUS detected over a 24-month period [1,014 low-risk, 290 intermediate-risk and 203 high-risk iMGUS), with median age 76.8 years and median 17 months of follow-up. Of 525 low-risk patients with ≥12-months follow-up, 475 (90%) had attended a further monitoring event. Of 88 intermediate-risk patients attending non-Consultant-led review (56 telephone and 32 F2F), 34 (39%) received further imaging and 10 (11%) had bone marrow biopsy. At last follow-up, 17 (19%) intermediate-risk patients had been moved to OxCOM remote monitoring, 65% had ongoing follow-up and 10 (11%) had been diagnosed with malignancy [2 MM, 3 smouldering MM, 2 Waldenström macroglobulinemia (WM), 2 lymphoma and 1 AL amyloidosis). Of 63 high-risk patients attending urgent Consultant-led F2F review, 41 (65%) had been diagnosed with malignancy (17 MM, 9 smouldering MM, 1 plasmacytoma, 9 WM, 2 lymphoma and 3 AL amyloidosis). **Conclusions:** We demonstrate the feasibility of a risk-adapted high-throughput clinical monitoring service for iMGUS. Immunology Laboratory led central oversight by stratifying patients to either OxCOM remote monitoring, routine OxCOM assessment or urgent F2F haematology review. The service therefore establishes a model to enable tailored follow-up and monitoring of iMGUS, which distributes healthcare resource towards higher-risk patients, whilst enabling sustainable monitoring for lower-risk patients.

Introduction: Smoldering multiple myeloma (SMM) is a heterogeneous condition comprised of patients with varying risk of progression to multiple myeloma (MM). Existing models to predict the risk of progression to active disease are based on MM markers from a single time point at initial presentation without regard to marker evolution over time. In this study, we assessed the effect of dynamic temporal changes in the free light chain ratio (FLCr) on the risk of progression from SMM to MM. **Methods:** We performed a retrospective analysis of patients diagnosed with SMM between 2002 and 2019 at Memorial Sloan Kettering Cancer Center with follow-up to 2022. Only patients with available FLCs (Freelite, The Binding Site) at diagnosis were included. Baseline laboratory, pathology, and imaging data, as well as date of diagnosis and progression, were manually reviewed. Progression from SMM to active MM was defined according to the diagnostic criteria at the time of progression or initiating treatment for active MM. Serial FLC levels between the date of diagnosis and progression were obtained by computerized extraction. We assessed the time to progression (TTP) using the Kaplan-Meier method, with log-rank tests for comparison between groups. We used Cox regression to estimate the

risk of progression with hazard ratios (HRs) and 95% confidence intervals (CIs). **Results:** A total of 398 patients were included with a median age of 64 years and 55% male. The median baseline FLCr was 9.8 (interquartile range 3.3-34.3). During a median follow-up time of 84 months, 184 patients (46%) progressed to active MM with a median TTP of 94 months. Patients were divided into quintiles based on the baseline FLCr (Q1-Q5). Patients in Q5 had a FLCr from 26.6-94.8 and had an increased risk of a progression (median TTP 36 [95% CI: 29-62] months, HR 3.2 [1.9-5], p< 0.001) when compared to patients in Q1. Patients in Q4 (FLCr 11.3-26.6) had a median TTP of 102 (53-not reached) months and a HR of 1.7 (0.9 -2.9). For patients in Q1-Q3 (FLCr 1-11.2), the median TTP ranged from 128 to 213 months, and HRs were similar for patients in Q3 and Q2 compared to Q1. Patients were further stratified into groups based on the change in the FLCr at 1 year (ΔQ1-ΔQ5). Patients in ΔQ5 had a rise in FLCr (ΔFLCr) of >55% compared to their baseline. After 1 year, they had an increased risk of progression with a median TTP of 48 (21-116) months, and a HR of 2 (1.1-3.8) compared to patients in ΔQ1. Patients in ΔQ4 (ΔFLCr 17-55% increase from baseline) had a median TTP of 67 (39-not reached) months and a HR of 1.8 (0.9-3.3). For patients in ΔQ1-ΔQ3 (ΔFLCr < 17%), the median TTP ranged from 97 to 201 months. There was no significant difference in the HR for progression between patients in ΔQ3 and ΔQ2 compared to ΔQ1. **Conclusions:** In addition to baseline risk stratification based on the FLCr, changes in FLCr within the first year of diagnosis provide additional prognostic information to further guide the management of patients with SMM.

Clinical characteristics and risk of progression in patients with monoclonal gammopathy of uncertain significance: long-term experience in a single tertiary hospital

Elena Alejo[1], Borja Puertas[1], Cristina Agulló[1], Beatriz Rey-Búa[1], Ramon Garcia-Sanz[2], Noemi Puig[3], María-Victoria Mateos[4], Veronica Gonzalez-Calle[2]

[1]Hospital Universitario de Salamanca; [2]Departamento de Hematología, Hospital Universitario de Salamanca, (HUSA/IBSAL), Centro de Investigación del Cáncer-IBMCC (CSIC/USAL), CIBERONC; [3]Hospital Universitario de Salamanca Hematología. Instituto de investigación biomédica de Salamanca (IBSAL); [4]University Hospital of Salamanca/IBSAL/CIC/CIBERONC, Salamanca, Spain

Introduction: Monoclonal gammopathy of uncertain significance (MGUS) is a premalignant disease characterized by proliferation of aberrant plasma cells (aPC) with a high prevalence in the population over 50 years and annual risk of progression to multiple myeloma (MM) of 1%. Identification of factors associated to risk of progression is useful to individualize patient follow-up. The aim was to identify potential risk factors at diagnosis in MGUS and to validate previously published progression-risk models. **Methods:** An observational retrospective study was conducted including MGUS patients diagnosed at University Hospital of Salamanca between 1990 and 2022. MGUS was defined according to the criteria of the International Myeloma Working Group in 2014. Mayo Clinic and Burgos et al (MGUS-like phenotype) progression risk models were used. **Results:** The study is ongoing and, 700 patients have been reviewed so far, with a median age of 73 years (28-108). IgG was the most frequent isotype (67.6%), 11 were light-chain and 1 biclonal. Bone marrow aspiration at diagnosis was performed in 330 (47.1%) cases. Among those, median PC by morphology was 3% (0-9) and 6.7% had >95% aPC by multiparameter flow cytometry (MFC). When all variables were available, risk stratification according to the Mayo Clinic and the MGUS-like models were applied. With a median follow-up of 95 months (2-379), 5.4% progressed with a median time to progression of 378 months. Thirty-one patients progressed to MM, 1 to AL amyloidosis, 1 to light-chain deposition disease and 5 to lymphoproliferative disorders. In the univariant analysis, serum M protein>1.5 g/dL, abnormal free light chain ratio (FLCr), immunoparesia, >5% PC by morphology and >95% aPC by MFC were significantly associated with increased risk of progression, being the latter the only one identified as an independent prognostic factor for progression (Hazard ratio (HR) 4.6 [95% CI 1.3-17], p=0.020). Mayo Clinic model was applied in 463 (66.1%) patients. Considering low-risk group as a reference, low-intermediate group had significantly higher risk of progression (HR 3.8 [95% CI, 1.1-14.1], p=0.046); same as high-intermediate (HR 7.2 [95% CI 1.9-27.5], p=0.003) and high risk (HR 34.5 [95% CI 6.9-171.5], p< 0.001). MGUS-like model was applied in 330 (47.1%) patients: intermediate phenotype was significantly associated with increased risk of progression as compared to MGUS-like (HR 6.4 [95% CI 2.5-16.4], p< 0.001). **Conclusions:** (1) Distribution of MGUS isotypes in our series is consistent with other series, although the proportion of progression is lower. (2) The Mayo Clinic and the MGUS-like risk models were validated in our series. (3) Predictors of increased risk of progression were identified as having serum M protein>1.5 g/dL, abnormal FLCr, immunoparesia, >5% PC by morphology and >95% aPC by MFC. The latter was the only one identified as an independent prognostic factor for progression. (4) Analysis about entire series will be presented at the meeting.

Introduction: Monoclonal gammopathy of uncertain significance (MGUS) is a premalignant disease characterized by proliferation of aberrant plasma cells (aPC) with a high prevalence in the population over 50 years and annual risk of progression to multiple myeloma (MM) of 1%. Identification of factors associated to risk of progression is useful to individualize patient follow-up. The aim was to identify potential risk factors at diagnosis in MGUS and to validate previously published progression-risk models. **Methods:** An observational retrospective study was conducted including MGUS patients diagnosed at University Hospital of Salamanca between 1990 and 2022. MGUS was defined according to the criteria of the International Myeloma Working Group in 2014. Mayo Clinic and Burgos et al (MGUS-like phenotype) progression risk models were used. **Results:** The study is ongoing and, 700 patients have been reviewed so far, with a median age of 73 years (28-108). IgG was the most frequent isotype (67.6%), 11 were light-chain and 1 biclonal. Bone marrow aspiration at diagnosis was performed in 330 (47.1%) cases. Among those, median PC by morphology was 3% (0-9) and 6.7% had >95% aPC by multiparameter flow cytometry (MFC). When all variables were available, risk stratification according to the Mayo Clinic and the MGUS-like models were applied. With a median follow-up of 95 months (2-379), 5.4% progressed with a median time to progression of 378 months. Thirty-one patients progressed to MM, 1 to AL amyloidosis, 1 to light-chain deposition disease and 5 to lymphoproliferative disorders. In the univariant analysis, serum M protein>1.5 g/dL, abnormal free light chain ratio (FLCr), immunoparesia, >5% PC by morphology and >95% aPC by MFC were significantly associated with increased risk of progression, being the latter the only one identified as an independent prognostic factor for progression (Hazard ratio (HR) 4.6 [95% CI 1.3-17], p=0.020). Mayo Clinic model was applied in 463 (66.1%) patients. Considering low-risk group as a reference, low-intermediate group had significantly higher risk of progression (HR 3.8 [95% CI, 1.1-14.1], p=0.046); same as high-intermediate (HR 7.2 [95% CI 1.9-27.5], p=0.003) and high risk (HR 34.5 [95% CI 6.9-171.5], p< 0.001). MGUS-like model was applied in 330 (47.1%) patients: intermediate phenotype was significantly associated with increased risk of progression as compared to MGUS-like (HR 6.4 [95% CI 2.5-16.4], p< 0.001). **Conclusions:** (1) Distribution of MGUS isotypes in our series is consistent with other series, although the proportion of progression is lower. (2) The Mayo Clinic and the MGUS-like risk models were validated in our series. (3) Predictors of increased risk of progression were identified as having serum M protein>1.5 g/dL, abnormal FLCr, immunoparesia, >5% PC by morphology and >95% aPC by MFC. The latter was the only one identified as an independent prognostic factor for progression. (4) Analysis about entire series will be presented at the meeting.

Introduction: Multiple Myeloma (MM) progresses from monoclonal gammopathy of undetermined significance (MGUS) and/or smoldering MM (SMM). Despite similar primary genetic events as MM, MGUS and SMM are non- or low-proliferative; however, stable MGUS patients are at increased risk for osteoporotic

fracture and show reduced overall survival due to aging co-morbidities. Since oncogenes and DNA damage drive senescent growth arrest, we hypothesize that stable MGUS and SMM pre-malignant PCs exhibit senescence features. **Methods:** We performed gene set enrichment analysis (GSEA) of a published human PC gene array dataset (GSE5900). Immunostaining and fluorescent in situ hybridization were performed to evaluate senescence in MGUS, SMM and MM patient PCs and trephine bone biopsies from MGUS and SMM patients that progressed or not to MM. Lastly, quantitative PCR was used to validate senescence gene expression changes in MGUS, SMM, and MM PCs. **Results:** MGUS and SMM PCs exhibited significant enrichment for senescence phenotyping gene sets that were distinct from aging. PCs from bone marrow aspirates were identified as senescent based on the Loss of LMNB1 (LoL, < 50%) and senescence associated distension of satellites (SADS, ≥3/cell). PCs from patients with stable MGUS (N=4) exhibited increased percentage of senescent PCs compared to SMM and MM, while stable vs progressing SMM PCs (stable vs progressed ≤5 years, n=6-8) were unchanged. However, PCs from stable, but not progressing SMM, had increased expression of senescence genes (CDKN2A, TP53, BCL2, and IL1B). Both stable MGUS and SMM PCs showed a significant increase in the expression of the retrotransposable element, L1HS, which is increased with senescence, compared to PCs from SMM progressors. Trephine biopsy cells were scored as senescent based on LoL and loss of nuclear HMGB1. Stable MGUS patients exhibited increased percentage of senescent PCs compared to MM and MGUS patients that progressed ≤10 years (n=20-40). Senescent PCs in trephine biopsies correlated with senescence in the bone marrow microenvironment (BMME). Of interest, MGUS and SMM PCs from patients that progressed ≤10 years both exhibited a significant loss in neighboring senescent BMME compared to stable MGUS and SMM PCs. **Conclusions:** Overall, we demonstrate the presence of stage-specific senescence features in PCs from stable MGUS and SMM patients; these features are decreased in PCs from SMM progressors and MM, consistent with the protective effect of senescence against tumorigenesis. Thus, evaluating PC senescence in MGUS and SMM may have prognostic value to identify patients that will progress to MM. Importantly, given the increased risk for osteoporotic fracture and reduced overall survival in stable MGUS patients, the senescence-related protection against MM may come at the expense of premature aging. Ongoing studies are evaluating the safety and therapeutic utility of ablating pre-malignant senescent cells in MGUS and SMM.

High serum free light chains levels in African ancestry population screened for monoclonal gammopathy: implication for definition of FLC reference range accounting for renal function and race

Luca Bertamini[1], Jean-Baptiste Alberge[1], Habib El-Khoury[1], David Lee[1], Grace Fleming[1], Ciara Murphy[1], Maya Davis[1], Jacqueline Perry[1], Christian Cea-Curry[1], Audrey Pentz[2], Thulisile Hlubi[2], Natalie Smyth[3], Dhananjay Sakrikar[4], Mark Perkins[5], Stephen Harding[5], Derek Troske[4], Gad Getz[6], Timothy Rebbeck[1], Maureen Joffe[2], Catherine Marinac[1], Nelson Leung[7], Wenlong Carl Chen[8], Irene Ghobrial[1]

[1]Dana-Farber Cancer Institute; [2]Noncommunicable Diseases Research Division, Wits Health Consortium (PTY) Ltd, Johannesburg, South Africa; [3]Sydney Brenner Institute for Molecular Bioscience, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa; [4]The Binding Site Inc., Rochester, MN, USA; [5]The Binding Site Group Ltd., Birmingham, UK; [6]Broad Institute of MIT and Harvard, Cambridge, MA; [7]Mayo Clinic; [8]Sydney Brenner Institute for Molecular Science, University of the Witwatersrand

Introduction: Serum free light chains (sFLC) are important for diagnosis and prognosis of plasma cell dyscrasias and are known to be affected by kidney function and inflammation. In a biobanked population, African Americans (AA) were reported to have significantly higher Kappa (κ) and Lambda (λ) sFLC after adjusting for kidney function. We hypothesize that adjusted sFLC reference ranges are needed for individuals of African and European descent. **Methods:** We analyzed serum from 738 healthy Black South African (SA) and 3402 US individuals (AA+EA) as part of a study screening individuals at high risk of multiple myeloma (MM) and precursors (self-identify as Black or with family history of blood cancer). sFLC levels were measured using the Optilite® Freelite assay (The Biding Site). Participants were screened for Monoclonal Gammopathy of Undetermined Significance (MGUS; M protein ≥ 0.2 g/L) by MALDI-TOF mass spectrometry. Serum Cystatin C (Optilite®) was used to calculate estimated Glomerular Filtration Rate (eGFR) with CKD-EPI Cystatin C Equation (2012) formula for 752 individuals. Group medians were compared with Wilcoxon tests. Abnormal sFLCr was defined as a value outside the reference range with involved sFLC above the manufacturer's reference range. We used the 95% central interval (CI) for new sFLCr reference ranges. **Results:** After excluding individuals with Heavy Chain-MGUS, we included 654 SA, 326 AA, and 2,551 EA. Median age was 52, 56 and 58 respectively. Females were more common in the AA (74%) and EA (73%) vs SA (52%). Calculated median eGFR was 118 ml/min for SA and 112 for AA. HIV positivity was higher in SA (23%) than other groups (< 1%), 99% of whom were under treatment (Tenofovir 92%). The median free κ was higher in SA (32 mg/l,) than AA (18.1 mg/l,, +80%, p60 ml/min), excluding those with free κ and λ outside the 95% CI, we identified a new FLCr reference range of 0.80-2.38. **Conclusions:** We observed a significantly higher sFLC for Black (SA and AA) than White individuals (EA), independent of renal function. This could be due to genetic background and social and environmental factors, like HIV infection. While further validation is needed, we propose a new sFLC range for African ancestry populations with normal renal function.

[1]Mayo Clinic

Introduction: Solitary plasmacytomas are rare plasma cell neoplasms located in bone or extramedullary sites. Information on risk factors affecting disease-free survival (DFS) and survival outcomes is lacking. **Methods:** We conducted a retrospective study on 147 patients with plasmacytoma seen at the Mayo Clinic (January 1st, 2005 – June 30th, 2022). Our primary outcome was DFS, measured from the date of diagnosis to plasmacytoma recurrence or progression to multiple myeloma. We also performed a systematic review (1960 - 2022) and meta-analysis of 62 studies and 3487 patients with solitary plasmacytomas. Forest plots were constructed for each meta-analysis to examine and display study-level data using the random-effects model. **Results:** The median age at diagnosis was 60.7 years (range: 15.4 - 83.6). Patients with up to 10% clonal plasma cells in the bone marrow (plasmacytoma +, N=72) were older than those with a true solitary (N=75) plasmacytoma (63.5 vs. 56.2 years, p 5 mg/dl (HR= 1.9) and a positive urine immunofixation (HR= 3.4) were the only significant risk factors for earlier progression. In contrast, for solitary plasmacytoma, only a DFLC>5 mg/dl (HR= 2.7) retained significance. In the meta-analysis, most patients were male (66.1%) with a median age of 58 years and a tumor size of 4.9 cm. Radiation therapy was the main treatment, with 90.6% receiving it alone or in combination with other therapies. The objective response rate was 92.6%, with a 3-year DFS rate of 66.9%, 5-year DFS of 55%, and 10-year DFS of 42.1%. The 5-year overall survival (OS) rate was 79.6%, and the 10-year OS rate was 64.7%. There was a significant difference in the 5-year DFS rate between patients with bone plasmacytomas (51.1%) and extramedullary locations (69.8%), p< 0.01. The OS was numerically shorter in patients with bone plasmacytoma than with extramedullary plasmacytoma, respectively (76.7% vs. 81% at 5 years and 61% vs. 70.1% at 10 years, p=NS). **Conclusions:** The study provides important insight into survival outcomes and risk factors for plasmacytoma patients and highlights the importance of comprehensive disease staging at diagnosis.

Introduction: Smouldering myeloma(SMM) risk models are largely based on genetics and disease bulk at a single timepoint. Improved understanding of disease dynamics and the influence of immunity on progression will help refine models and design of interventional trials. COSMOS is a prospective multi-centre observational study running in the UK since 2021, examining tumour dynamics, immune function, and serial biopsies to track disease longitudinally. **Methods:** COSMOS enrols patients with previous history, newly diagnosed or suspected SMM. Clinical, radiological and laboratory features are recorded with regular blood and bone marrow(BM) sampling. All samples undergo initial flow cytometry for tumour and immune subsets with downstream bulk and single cell sequencing and deep immune profiling. **Results:** We recruited 167 patients, median age 69yr (range 27-85), 47.3% male. At entry 82% were SMM, 10.5% MGUS and 7.5% myeloma by CRAB criteria(excluded from subsequent results). Median (range) paraprotein, light chain ratio(LCr) and BM plasma cell percentage(BMPC%) were 18.5g/L(1-77), 8.28(1.04-638.9), and 15(5-60). 43.8% had one or more high-risk cytogenetic lesions. 30%, 28%, 25%, 17% were low, low-intermediate, intermediate, and high-risk(IMWG). 7(4.2%) had ultra high-risk(UHR) disease(SLiM criteria). Median follow-up 10months(range 1-24) with low rate of withdrawal (3.6%). At entry there was negative correlation between BMPC%/paraprotein and albumin(p=0.02 and p< 0.001). Paraprotein negatively correlated with haemoglobin(p=0.04) and LDH(p=0.04). BMPC% negatively correlated with CD11b+ myeloid cells(p=0.019). CD4/8+ T-cells, Tregs, and NK-cells did not correlate with disease bulk or other immune cell frequencies. In total 21 patients progressed at median 11m(range 1-130) from diagnosis, 12 within 3 months of study entry and were excluded from our analysis of risk factors based on registration parameters. 12(57%) had bone disease. Of the 9 progressing on study at median 28m(4-130) from diagnosis. 66% were high-risk with paraprotein, LCr, and BMPC% significantly higher than non-progressors. No significantly different alterations in routine biochemical parameters or immune cells by 12m from entry were seen between progressors and non-progressors. 6/7 UHR patients have not progressed. Our laboratory pipeline includes scRNAseq on BM cells. For one progressing patient, we observed longitudinal clonal expansion of CD8+ T cell TCR clones alongside accumulation of proliferating(MKI67+TYMS+) tumour cells consistent with anti-tumour response. **Conclusions:** COSMOS has good and steady recruitment of UK SMM patients. BMPC% at entry correlates with decreasing haematopoietic reserve

We also performed a systematic review (1960 - 2022) and meta-analysis of 62 studies and 3487 patients with solitary plasmacytomas. Forest plots were constructed for each meta-analysis to examine and display study-level data using the random-effects model. **Results:** The median age at diagnosis was 60.7 years (range: 15.4 - 83.6). Patients with up to 10% clonal plasma cells in the bone marrow (plasmacytoma +, N=72) were older than those with a true solitary (N=75) plasmacytoma (63.5 vs. 56.2 years, p 5 mg/dl (HR= 1.9) and a positive urine immunofixation (HR= 3.4) were the only significant risk factors for earlier progression. In contrast, for solitary plasmacytoma, only a DFLC>5 mg/dl (HR= 2.7) retained significance. In the meta-analysis, most patients were male (66.1%) with a median age of 58 years and a tumor size of 4.9 cm. Radiation therapy was the main treatment, with 90.6% receiving it alone or in combination with other therapies. The objective response rate was 92.6%, with a 3-year DFS rate of 66.9%, 5-year DFS of 55%, and 10-year DFS of 42.1%. The 5-year overall survival (OS) rate was 79.6%, and the 10-year OS rate was 64.7%. There was a significant difference in the 5-year DFS rate between patients with bone plasmacytomas (51.1%) and extramedullary locations (69.8%), p< 0.01. The OS was numerically shorter in patients with bone plasmacytoma than with extramedullary plasmacytoma, respectively (76.7% vs. 81% at 5 years and 61% vs. 70.1% at 10 years, p=NS). **Conclusions:** The study provides important insight into survival outcomes and risk factors for plasmacytoma patients and highlights the importance of comprehensive disease staging at diagnosis.

Introduction: Smouldering myeloma(SMM) risk models are largely based on genetics and disease bulk at a single timepoint. Improved understanding of disease dynamics and the influence of immunity on progression will help refine models and design of interventional trials. COSMOS is a prospective multi-centre observational study running in the UK since 2021, examining tumour dynamics, immune function, and serial biopsies to track disease longitudinally. **Methods:** COSMOS enrols patients with previous history, newly diagnosed or suspected SMM. Clinical, radiological and laboratory features are recorded with regular blood and bone marrow(BM) sampling. All samples undergo initial flow cytometry for tumour and immune subsets with downstream bulk and single cell sequencing and deep immune profiling. **Results:** We recruited 167 patients, median age 69yr (range 27-85), 47.3% male. At entry 82% were SMM, 10.5% MGUS and 7.5% myeloma by CRAB criteria(excluded from subsequent results). Median (range) paraprotein, light chain ratio(LCr) and BM plasma cell percentage(BMPC%) were 18.5g/L(1-77), 8.28(1.04-638.9), and 15(5-60). 43.8% had one or more high-risk cytogenetic lesions. 30%, 28%, 25%, 17% were low, low-intermediate, intermediate, and high-risk(IMWG). 7(4.2%) had ultra high-risk(UHR) disease(SLiM criteria). Median follow-up 10months(range 1-24) with low rate of withdrawal (3.6%). At entry there was negative correlation between BMPC%/paraprotein and albumin(p=0.02 and p< 0.001). Paraprotein negatively correlated with haemoglobin(p=0.04) and LDH(p=0.04). BMPC% negatively correlated with CD11b+ myeloid cells(p=0.019). CD4/8+ T-cells, Tregs, and NK-cells did not correlate with disease bulk or other immune cell frequencies. In total 21 patients progressed at median 11m(range 1-130) from diagnosis, 12 within 3 months of study entry and were excluded from our analysis of risk factors based on registration parameters. 12(57%) had bone disease. Of the 9 progressing on study at median 28m(4-130) from diagnosis. 66% were high-risk with paraprotein, LCr, and BMPC% significantly higher than non-progressors. No significantly different alterations in routine biochemical parameters or immune cells by 12m from entry were seen between progressors and non-progressors. 6/7 UHR patients have not progressed. Our laboratory pipeline includes scRNAseq on BM cells. For one progressing patient, we observed longitudinal clonal expansion of CD8+ T cell TCR clones alongside accumulation of proliferating(MKI67+TYMS+) tumour cells consistent with anti-tumour response. **Conclusions:** COSMOS has good and steady recruitment of UK SMM patients. BMPC% at entry correlates with decreasing haematopoietic reserve

and decreasing albumin. In SMM, LDH does not appear to correlate with disease bulk. Broad immune cell subsets does not inform on risk or progression, indicating the need for our ongoing in-depth immune analysis. Longitudinal scRNA seq may give insight into immune processes associated with progression.

Introduction: Current risk scoring systems for smoldering multiple myeloma (SMM) are based on disease burden where patients with M-spike >2 g/dL, bone marrow plasma cells >20%, and free light chain ratio >20 are deemed at high risk for progression. Here, we assessed information on the dynamics of the M-spike concentration for predicting progression to multiple myeloma (MM). **Methods:** We analyzed all patients with SMM managed at Memorial Sloan Kettering Cancer Center between 2002-2019 with follow up to 2022. Descriptive statistics, Kaplan Meier curves, and Cox regression were used to analyze the risk of progression in relation to baseline M-spike and change in M-spike concentration. Disease progression was defined as fulfilling CRAB criteria and/or starting treatment for MM. Patient who progressed within the first 3 months of SMM diagnosis were excluded. **Results:** We included 398 patients with SMM, 55% men and median age was 63.6 years. The median baseline M-spike level was 1.3 g/dL. Patients were stratified into quintiles with the highest risk of progression seen in quintile 5 (Q5), i.e. baseline M-spike of >=2.2 g/dL, where the median time to progression (TTP) was 29 months (95% confidence interval [CI] 24-64 months). The TTP for patients in Q4, i.e. M-spike of 1.6-2.2 g/dL, was 67 months (95% CI 51-115 months). The TTP was longer for patients with lower M-spike and was similar in Q1-3 (M-spike 0-1.6 g/dL) where the TTP ranged from 112-138 months. During the first year of follow up, 11% of SMM patients progressed to MM. The rate of change (delta) in M-spike during year 1 of follow up translated into a higher risk of progression. In patients in the highest quintile of change (deltaQ5), delta M-spike of 0.3 g/dL or more during the first year, the median TTP was 22 months. For SMM patients with baseline M-spike concentrations in Q5, the hazard ratio (HR) for progression to MM was 3 times higher (HR=2.9, 95% CI 1.8-4.6) compared to patients in Q1. Similarly, in SMM patients with the highest rate of change (deltaQ5), the HR was 2.9, (95% CI 1.6-5.4) compared to patients in deltaQ1 after year 1. Interestingly, of the 11% (n=44) of patients who progressed during the first year, only 45% were in M-spike Q5 (n=20) at baseline. Of the remaining patients who progressed to MM during the first year of follow up, 9 were from baseline Q4 while 12 were from Q1-3, and 3 had no baseline M-spike. **Conclusions:** In summary, we confirmed that a higher baseline M-spike was associated with a higher risk of progression from SMM to MM. However, among patients who progressed at year 1 of follow up, 55% were not in the baseline Q5 M-spike group. Furthermore, we found that patients with a high rate of change in M-spike during the first year had a similar rate of progression to MM compared to SMM patients with a high baseline M-spike. Thus, both burden of disease and disease biology reflected in a rapid change in M-spike should be considered when predicting the risk of progression in patients with SMM.

Introduction: Patients with hematological malignancies, including multiple myeloma (MM), experience sub-optimal responses to SARS-CoV-2 vaccination. Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smoldering Multiple Myeloma (SMM) are precursors to MM and exhibit altered immune cell composition and function. The SARS-CoV-2 pandemic and the subsequent population-wide vaccination represent an opportunity to study the real-life immune response to a common antigen. Here, we present updated results from the IMPACT study, a study we launched in November 2020 to characterize the effect of plasma cell premalignancy on response to SARS-CoV-2 vaccination (vx). **Methods:** We performed: (i) ELISA for SARS-CoV-2-specific antibodies on 1,887 peripheral blood (PB) samples (237 healthy donors (HD), and 550 MGUS, 947 SMM, and 153 MM patients) drawn pre- and post-vx; (ii) single-cell RNA, T cell receptor (TCR), and B cell receptor (BCR) sequencing (10x Genomics) on 224 PB samples (26 HD, and 20 MGUS, 48 SMM, and 24 MM patients) drawn pre- and post-vx; (iii) plasma cytokine profiling (Olink) on

and decreasing albumin. In SMM, LDH does not appear to correlate with disease bulk. Broad immune cell subsets does not inform on risk or progression, indicating the need for our ongoing in-depth immune analysis. Longitudinal scRNA seq may give insight into immune processes associated with progression.

Introduction: Patients with hematological malignancies, including multiple myeloma (MM), experience sub-optimal responses to SARS-CoV-2 vaccination. Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smoldering Multiple Myeloma (SMM) are precursors to MM and exhibit altered immune cell composition and function. The SARS-CoV-2 pandemic and the subsequent population-wide vaccination represent an opportunity to study the real-life immune response to a common antigen. Here, we present updated results from the IMPACT study, a study we launched in November 2020 to characterize the effect of plasma cell premalignancy on response to SARS-CoV-2 vaccination (vx). **Methods:** We performed: (i) ELISA for SARS-CoV-2-specific antibodies on 1,887 peripheral blood (PB) samples (237 healthy donors (HD), and 550 MGUS, 947 SMM, and 153 MM patients) drawn pre- and post-vx; (ii) single-cell RNA, T cell receptor (TCR), and B cell receptor (BCR) sequencing (10x Genomics) on 224 PB samples (26 HD, and 20 MGUS, 48 SMM, and 24 MM patients) drawn pre- and post-vx; (iii) plasma cytokine profiling (Olink) on

106 PB samples (32 HD, and 38 MGUS and 36 SMM patients) drawn pre- and post-vx; and (iv) bulk TCR sequencing (Adaptive Biotechnologies) on 8 PB samples from 4 patients (2 MGUS, 2 SMM) drawn pre- and post-vx. **Results:** Patients with MGUS and SMM achieved comparable antibody titers to HD two months post-vx. However, patient titers waned significantly faster, and 4 months post-vx we observed significantly lower titers in both MGUS (Wilcoxon rank-sum, p=0.030) and SMM (p=0.010). These results indicate impaired humoral immune response in patients with MGUS and SMM. At baseline, the TCR repertoire was significantly less diverse in patients with SMM compared to HD (Wilcoxon rank-sum, p=0.039), while no significant difference was observed in the BCR repertoire (p=0.095). Interestingly, a significant increase in TCR repertoire diversity was observed post-vx in patients with SMM (paired t-test, p=0.014), indicating rare T cell clone recruitment in response to vaccination. In both HD and patients, recruited clones showed upregulation of genes associated with CD4+ naïve and memory T cells, suggesting at least partial preservation of the T cell response in SMM, which was confirmed by bulk TCR-sequencing in 4 patients. Lastly, by cytokine profiling, we observed a defect in IL-1β and IL-18 induction post-vx in patients with SMM compared to HD (Wilcoxon rank-sum, p=0.047 and p=0.015, respectively), two key monocyte-derived mediators of acute inflammation, suggesting an altered innate immune response as well. **Conclusions:** Taken together, our findings highlight that despite the absence of clinical manifestations, plasma cell premalignancy is associated with defects in both innate and adaptive immune responses. Therefore, patients with plasma cell premalignancy may require adjusted vaccination strategies for optimal immunization.

Single-cell RNA sequencing of circulating tumor cells in precursor myeloma patients reveals early mechanisms of disease dissemination

Elizabeth Lightbody[1], Danielle Firer[2], Romanos Sklavenitis-Pistofidis[1], Junko Tsuji[2], Michael Agius[1], Ankit Dutta[1], Ting Wu[2], Hadley Barr[1], Mahshid Rahmat[1], Yoshinobu Konishi[1], Michelle Aranha[1], Jean-Baptiste Alberge[1], Nang Kham Su[1], Cody Boehner[1], Laura Hevenor[1], Habib El-Khoury[1], Katherine Towle[1], Christian Cea-Curry[1], Erica Horowitz[1], Jacqueline Perry[1], Anna Cowan[1], Daniel Auclair[3], Catherine Marinac[1], Gad Getz[2], Irene Ghobrial[1]

[1]Dana-Farber Cancer Institute; [2]Broad Institute of MIT & Harvard; [3]AstraZeneca

Introduction: Multiple Myeloma (MM) is preceded by the precursors Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smoldering Multiple Myeloma (SMM). BM biopsies are useful to monitor disease progression, but they are not routinely collected from precursor patients for disease monitoring. Profiling circulating tumor cells (CTCs) from peripheral blood (PB) may provide information for the non-invasive surveillance of precursors and nominate novel PB-based biomarkers to identify high-risk patients. **Methods:** Paired PB and BM aspirates were collected from 73 individuals, including patients with MGUS (n=9), SMM (n=40), NDMM (n=12) and healthy individuals (n=12). Malignant PCs underwent 5' single-cell RNA sequencing (scRNA-seq) and single-cell B-cell receptor sequencing (scBCR-seq) (10x Genomics). To differentiate malignant from normal PCs, we used clonal V(D)J rearrangements. Differential expression (DE) and composition analyses were conducted using Wilcoxon's rank-sum tests. **Results:** We profiled 351,225 BM tumor cells and 55,110 CTCs. High-risk SMM patients had significantly more CTCs compared to MGUS patients (p=0.024) and low-risk SMM (p=0.042). A median of 5, 26, and 47 CTCs were present per mL of blood from low (n=15), intermediate (n=10), and high-risk (n=15) SMM patients as defined by the International Myeloma Working Group's 2/20/20 criteria, suggesting sequencing-based CTC enumeration captures prognostically relevant differences in tumor burden. High expression of driver genes upregulated in patients with translocations, including CCND1, NSD2, and MAF, were detected in both BM tumor cells and CTCs in patients with t(11;14), t(4;14), and t(14;16) as identified by fluorescence in situ hybridization (FISH). In 5 patients with normal or inconclusive FISH results, we observed high levels of CCND2 and MAF in both BM and CTCs, indicating scRNA-seq can detect missed prognostically relevant cytogenetic abnormalities. DE analysis of CTCs vs. BM tumor cells highlighted transcriptional similarity between BM and CTCs, validating their utility as a surrogate for analyzing BM tumor cells. DE analysis also revealed 8 genes significantly upregulated and 3 genes significantly downregulated in CTCs compared to BM tumor cells, providing novel insights into genes involved in PC circulatory potential. Pathway enrichment analysis revealed genes upregulated in CTCs were associated with epithelial mesenchymal transition, interferon response, and inflammation, consistent with CTC studies on MM patients, suggesting these pathways are dysregulated earlier in the disease continuum. **Conclusions:** In the largest scRNA-seq study on CTCs to date, we demonstrate the utility of CTC-based molecular profiling for prognostication of patients with early-stage disease and provide novel insights into PC circulatory potential. Additional analyses are ongoing to gain further insight into intra-patient CTC heterogeneity and define high-risk disease CTC signatures that emerge throughout the MM disease continuum.

Prevalence of metabolic comorbidities and viral co-infections in monoclonal gammopathy: a retrospective analysis

Tinatin Muradashvili[1], Mansen Yu[1], Natalia Neparidze[1]

[1]Yale University

Introduction: Monoclonal gammopathy (MG) encompasses a spectrum of related diseases, with monoclonal gammopathy of undetermined significance (MGUS) being the most prevalent, serving as a precursor of smoldering and clinical multiple myeloma. While the association between gammopathies, metabolic conditions and antigenic stimulation has long been recognized, the precise etiopathogenic mechanism remains to be elucidated. The aim of this study is to assess the prevalence of metabolic comorbidities and

106 PB samples (32 HD, and 38 MGUS and 36 SMM patients) drawn pre- and post-vx; and (iv) bulk TCR sequencing (Adaptive Biotechnologies) on 8 PB samples from 4 patients (2 MGUS, 2 SMM) drawn pre- and post-vx. **Results:** Patients with MGUS and SMM achieved comparable antibody titers to HD two months post-vx. However, patient titers waned significantly faster, and 4 months post-vx we observed significantly lower titers in both MGUS (Wilcoxon rank-sum, p=0.030) and SMM (p=0.010). These results indicate impaired humoral immune response in patients with MGUS and SMM. At baseline, the TCR repertoire was significantly less diverse in patients with SMM compared to HD (Wilcoxon rank-sum, p=0.039), while no significant difference was observed in the BCR repertoire (p=0.095). Interestingly, a significant increase in TCR repertoire diversity was observed post-vx in patients with SMM (paired t-test, p=0.014), indicating rare T cell clone recruitment in response to vaccination. In both HD and patients, recruited clones showed upregulation of genes associated with CD4+ naïve and memory T cells, suggesting at least partial preservation of the T cell response in SMM, which was confirmed by bulk TCR-sequencing in 4 patients. Lastly, by cytokine profiling, we observed a defect in IL-1β and IL-18 induction post-vx in patients with SMM compared to HD (Wilcoxon rank-sum, p=0.047 and p=0.015, respectively), two key monocyte-derived mediators of acute inflammation, suggesting an altered innate immune response as well. **Conclusions:** Taken together, our findings highlight that despite the absence of clinical manifestations, plasma cell premalignancy is associated with defects in both innate and adaptive immune responses. Therefore, patients with plasma cell premalignancy may require adjusted vaccination strategies for optimal immunization.

Introduction: Multiple Myeloma (MM) is preceded by the precursors Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smoldering Multiple Myeloma (SMM). BM biopsies are useful to monitor disease progression, but they are not routinely collected from precursor patients for disease monitoring. Profiling circulating tumor cells (CTCs) from peripheral blood (PB) may provide information for the non-invasive surveillance of precursors and nominate novel PB-based biomarkers to identify high-risk patients. **Methods:** Paired PB and BM aspirates were collected from 73 individuals, including patients with MGUS (n=9), SMM (n=40), NDMM (n=12) and healthy individuals (n=12). Malignant PCs underwent 5' single-cell RNA sequencing (scRNA-seq) and single-cell B-cell receptor sequencing (scBCR-seq) (10x Genomics). To differentiate malignant from normal PCs, we used clonal V(D)J rearrangements. Differential expression (DE) and composition analyses were conducted using Wilcoxon's rank-sum tests. **Results:** We profiled 351,225 BM tumor cells and 55,110 CTCs. High-risk SMM patients had significantly more CTCs compared to MGUS patients (p=0.024) and low-risk SMM (p=0.042). A median of 5, 26, and 47 CTCs were present per mL of blood from low (n=15), intermediate (n=10), and high-risk (n=15) SMM patients as defined by the International Myeloma Working Group's 2/20/20 criteria, suggesting sequencing-based CTC enumeration captures prognostically relevant differences in tumor burden. High expression of driver genes upregulated in patients with translocations, including CCND1, NSD2, and MAF, were detected in both BM tumor cells and CTCs in patients with t(11;14), t(4;14), and t(14;16) as identified by fluorescence in situ hybridization (FISH). In 5 patients with normal or inconclusive FISH results, we observed high levels of CCND2 and MAF in both BM and CTCs, indicating scRNA-seq can detect missed prognostically relevant cytogenetic abnormalities. DE analysis of CTCs vs. BM tumor cells highlighted transcriptional similarity between BM and CTCs, validating their utility as a surrogate for analyzing BM tumor cells. DE analysis also revealed 8 genes significantly upregulated and 3 genes significantly downregulated in CTCs compared to BM tumor cells, providing novel insights into genes involved in PC circulatory potential. Pathway enrichment analysis revealed genes upregulated in CTCs were associated with epithelial mesenchymal transition, interferon response, and inflammation, consistent with CTC studies on MM patients, suggesting these pathways are dysregulated earlier in the disease continuum. **Conclusions:** In the largest scRNA-seq study on CTCs to date, we demonstrate the utility of CTC-based molecular profiling for prognostication of patients with early-stage disease and provide novel insights into PC circulatory potential. Additional analyses are ongoing to gain further insight into intra-patient CTC heterogeneity and define high-risk disease CTC signatures that emerge throughout the MM disease continuum.

Prevalence of metabolic comorbidities and viral co-infections in monoclonal gammopathy: a retrospective analysis

Tinatin Muradashvili[1], Mansen Yu[1], Natalia Neparidze[1]

[1]Yale University

Introduction: Monoclonal gammopathy (MG) encompasses a spectrum of related diseases, with monoclonal gammopathy of undetermined significance (MGUS) being the most prevalent, serving as a precursor of smoldering and clinical multiple myeloma. While the association between gammopathies, metabolic conditions and antigenic stimulation has long been recognized, the precise etiopathogenic mechanism remains to be elucidated. The aim of this study is to assess the prevalence of metabolic comorbidities and

viral infections in a large population with monoclonal gammopathy, providing insights into the disease's pathophysiology. **Methods:** We conducted a retrospective chart review at a single center for patients aged 18 years and older, diagnosed with monoclonal gammopathy between 2014 and 2020. We excluded patients without documented immunofixation or serum protein electrophoresis studies, as well as those with "faint" or "extremely faint" monoclonal components, resulting in a final data set of 1515 patients. Variables of interest including age, race, ethnicity, gender, hyperlipidemia, diabetes, BMI, HIV, human papillomavirus (HPV), hepatitis C (HCV) and hepatitis B (HBV) status were identified by a combination of direct extraction from the EMR by the Joint Data Analytics Team and manual review of laboratory values, provider notes and scanned documents. **Results:** Among the 1515 patients diagnosed with monoclonal gammopathy, the average age was 76.36 (±11.3) years. The majority of patients (79.4%) self-identified as White, while 238 (15.7%) as Black/African American and 10 (0.7%) as Asian. Non-Hispanic individuals accounted for 1428 (94.3%) of the patients. The mean body mass index (BMI) was 27.5 (±6.73) years. Diabetes mellitus was reported in 614 (40.5%) cases, and hyperlipidemia was observed in 1362 (89.9%) cases. A total of 1236 (81.6%) patients used a statin at some point. Dyslipidemia and diabetes are estimated to affect 53% and 11.3% of the U.S. population, respectively. Among individuals aged 65 and older, the prevalence of dyslipidemia and diabetes is reported to be 60.3% and 21.2%, respectively. In our cohort, viral comorbidities included HIV in 20 (1.3%) patients and HPV in 14 (0.9 %) patients. In comparison, 12.6 per 100,000 people in the U.S. had HIV in 2019. Additionally, 49 out of 812 (6%) patients had positive HCV antibodies, compared to 1.7% of US adults. There were 56 of 711 (7.9%) patients with HBV infections. As of May 2023, out of the total 1515 patients, 485 (32%) deaths were reported. **Conclusions:** Patients with MG demonstrate significantly higher rates of dyslipidemia, diabetes, HIV, and positive HCV antibodies compared to the general US adult population. These findings highlight the importance of metabolic and viral infections in MG and emphasize the need for additional research on biologic drivers to guide preventative strategies.

Phase II trial of daratumumab, bortezomib, lenalidomide and dexamethasone in high-risk smoldering multiple myeloma

Omar Nadeem[1], Robert Redd[1], Clifton Mo[1], Jacob Laubach[1], Paul G. Richardson[1], Julia Prescott[1], Marjorie Marto[1], Christine Davie[1], Caroline Ricciardi[1], Elizabeth Murphy[1], Meredith Bertoni[1], Dechen Choden[1], Sophie Magidson[1], Brian Sheehan[1], Hira Shrestha[1], Adam S. Sperling[1], Elizabeth K. O'Donnell[2], Irene M. Ghobrial[1]

[1]Dana-Farber Cancer Institute, Boston, MA, USA; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA

Introduction: Lenalidomide has shown to delay progression in patients with high-risk smoldering multiple myeloma (HR-SMM). Curative intent trials with carfilzomib-based therapy and stem cell transplantation are under investigation in HR-SMM, leading to deep responses but with concern for treatment-related toxicities (Mateos ASH 2022). Daratumumab, bortezomib, lenalidomide and dexamethasone (D-RVD) has shown high rates of minimal residual disease (MRD) negativity in MM (Voorhees Blood 2020). Thus, we proposed to examine the activity and safety of D-RVD in patients with HR-SMM. **Methods:** This is a phase II, open label study evaluating D-RVD in HR-SMM. Eligibility criteria included HR-SMM per Mayo 2018 "20-2-20" model and other previously established criteria including Mayo 2008 criteria, presence of immunoparesis, evolving type of SMM, and high risk FISH. Treatment with D-RVD is 2 years (24 cycles) with daratumumab subcutaneous (SQ) per standard dose and schedule, bortezomib SQ on days 1, 8, 15 for cycles 1-6 and then biweekly until completion of cycle 24 and lenalidomide on days 1-21 with weekly dexamethasone. All eligible patients undergo stem cell collection after 6 cycles of therapy. The primary objective is rate of MRD-negativity at 2 years. Secondary objectives include PFS, ORR, and safety. The trial has been amended to include part 2, which will randomize patients that are MRD positive after 2 years to observation vs continued therapy with daratumumab and lenalidomide for an additional 24 months. The primary objective of part 2 is rate of MRD conversion from positive to negative. **Results:** At the time of data cut off, 30 patients have been enrolled to part 1 with a median follow up of 14 months. The median age is 60 years old (range 36-77). Ninety percent of patients were classified as either high (18, 60%) or intermediate risk (9, 30%) per Mayo 2018 criteria with median plasmacytosis of 20%, median M protein of 2.17 g/dl and median FLC ratio of 8.1. Twelve patients (40%) had high-risk FISH results (10 with 1q gain, 2 with t(4;14), 1 with t(14;16) and 1 with del 17p). Most common grade 3 toxicities included neutropenia (17%), ALT increased (10%), hypertension (7%) and diarrhea (7%). Upper respiratory infections occurred in 66% of patients (COVID 19 infection in 10 patients, only 1 grade 3). No patients discontinued therapy due to toxicity. The overall response rate is 87% with 40% CR, 23% VGPR and 23% PR. Sixty-three percent of patients achieved VGPR or greater. MRD was evaluable in 24 patients with at least 6 months of follow up and MRD negativity rate is 58% (14/24) and 38% (9/24) at thresholds of 10-5 and 10-6, respectively. No patients have progressed on treatment. Stem cell collection was successful in all eligible patients with average stem cell yield of 5.57 x 10-6 CD34+ cells/kg. **Conclusions:** D-RVD in HR-SMM demonstrates significant activity, including high rates of MRD-negative disease, and has a similar toxicity profile to MM.

All eligible patients undergo stem cell collection after 6 cycles of therapy. The primary objective is rate of MRD-negativity at 2 years. Secondary objectives include PFS, ORR, and safety. The trial has been amended to include part 2, which will randomize patients that are MRD positive after 2 years to observation vs continued therapy with daratumumab and lenalidomide for an additional 24 months. The primary objective of part 2 is rate of MRD conversion from positive to negative. **Results:** At the time of data cut off, 30 patients have been enrolled to part 1 with a median follow up of 14 months. The median age is 60 years old (range 36-77). Ninety percent of patients were classified as either high (18, 60%) or intermediate risk (9, 30%) per Mayo 2018 criteria with median plasmacytosis of 20%, median M protein of 2.17 g/dl and median FLC ratio of 8.1. Twelve patients (40%) had high-risk FISH results (10 with 1q gain, 2 with t(4;14), 1 with t(14;16) and 1 with del 17p). Most common grade 3 toxicities included neutropenia (17%), ALT increased (10%), hypertension (7%) and diarrhea (7%). Upper respiratory infections occurred in 66% of patients (COVID 19 infection in 10 patients, only 1 grade 3). No patients discontinued therapy due to toxicity. The overall response rate is 87% with 40% CR, 23% VGPR and 23% PR. Sixty-three percent of patients achieved VGPR or greater. MRD was evaluable in 24 patients with at least 6 months of follow up and MRD negativity rate is 58% (14/24) and 38% (9/24) at thresholds of 10-5 and 10-6, respectively. No patients have progressed on treatment. Stem cell collection was successful in all eligible patients with average stem cell yield of 5.57 x 10-6 CD34+ cells/kg. **Conclusions:** D-RVD in HR-SMM demonstrates significant activity, including high rates of MRD-negative disease, and has a similar toxicity profile to MM.

Introduction: Multiple myeloma (MM) is usually diagnosed in an advanced stage, which is associated with end-organ failure, inferior quality of life and survival, and increased costs for healthcare institutions. MM precursor stages (MGUS and SMM) can be detected easily through blood protein tests. A prospective, nationwide, screening study performed in Iceland, has detected MGUS in 4.9% and SMM in 0.5% of adults >49 years. However, there is still no recommendation regarding the benefits of population screening for MM precursor diseases. The objective of this research is to assess the prevalence of monoclonal plasma cell disorders in the adult population in Uruguay and evaluate the progression to active disease. **Methods:** A prospective, single-cohort, nationwide descriptive study conducted at Hospital de Clínicas, Montevideo, Uruguay. Residents ≥ 40 years were invited to participate. Recruitment started in October 2021 and ended in October 2022. Patients with a previously known plasma cell disorder were excluded. Medical history was obtained in all cases. CAPILLARYS 2 Flex Piercing was used for Protein and Immunotyping analyses, Hydrasys 2 for immunofixation, and Freelite (The Binding Site) for serum-free light chains. If a monoclonal component (MC) was detected, patients were evaluated according to current IMWG recommendations. Patients diagnosed or progressed to active disease were offered early treatment. **Results:** 3905 patients were included; the median age was 56 years (40-104) IQR 17, and 58.4% were females. A MC was found in 104 patients (prevalence 2.7%), with a median age of 63 years (40-88) IQR 17, 54.8% were females. Patients without MC had a median age of 55 years (40-104) IQR 17. The median value of the MC was 0.5 g/dl, (0.1-2 g/dl) IQR 0.5. 10.6% had a non-quantifiable MC. 3.8% had a bi-clonal MC. MC was IgG 76%, IgA 13.4%, IgM 7.7%, Kappa 1.9%, Lambda 1%. The median value of sFLC kappa, lambda, and ratio (rFLC) were 23.5 mg/L (IQR 24), 18.5 mg/L (IQR 17), and 1.3 (IQR 0.83) respectively. An abnormal rFLC was found in 32% (33/102). Out of 102 patients, 54 were low-risk MGUS, 34 intermediate-low-risk MGUS, 8 intermediate-high-risk MGUS, 1 SMM, 3 active MM, and 2 asymptomatic Waldenstrom Macroglobulinemia. The patients with active MM had no end-organ failure, and treatment started within 1 month from diagnosis. No significant association was found between MC and gender or comorbidities. 1% of patients had a family history of MM. The prevalence of MC according to age subgroups was 1.26% in 40-49 years, 1.92% in 50-59 years, 3.11% in 60-69 years, 6.78% in 70-79 years, and 7.14% in >80 years. Age >55 years was associated with a significant risk of monoclonal gammopathy (OR 2.9; IC 95% 1.87-4.5, p< 0.01). **Conclusions:** The prevalence of MGUS was 2.45% and SMM was 0.03%. Age >50 years increases significantly the risk of MC. 3 patients were diagnosed with asymptomatic active disease.

Single-cell RNA sequencing of 1.3 million plasma cells from patients with MGUS and SMM

Romanos Sklavenitis-Pistofidis[1], Elizabeth Lightbody[1], Junko Tsuji[2], Michael Agius[1], Mahshid Rahmat[1], Yoshinobu Konishi[1], Ting Wu[2], Michelle Aranha[1], Danielle Firer[2], Nicholas Haradhvala[2], Gad Getz[2,3], Irene Ghobrial[1]

[1]Dana-Farber Cancer Institute; [2]Broad Institute of MIT & Harvard; [3]Massachusetts General Hospital Cancer Center

Introduction: Patients with Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smoldering Multiple Myeloma (SMM) exhibit variable risk of progression to full-blown Multiple Myeloma (MM), which cannot be fully explained by differences in tumor burden or genetic alterations. Therefore, characterizing non-genetic changes in malignant plasma cells may help to identify novel mechanisms of disease progression and improve prognostication. **Methods:** Here, we performed single-cell RNA and V(D)J-sequencing on 245 samples from 36 patients with MGUS, 136 patients with SMM, 37 patients with MM, and 25 healthy donors. Libraries were prepared with the Chromium Single-cell 5' Gene Expression and V(D)J enrichment kit by 10X Genomics and sequenced at the Genomics Platform of the Broad Institute of MIT and Harvard (Cambridge, MA). **Results:** Overall, we sequenced 1,318,218 plasma cells, including 960,998 malignant and 357,220 normal plasma cells. By comparing tumor cells between patients and healthy donors, as well as between patients from different risk stages, we derived an expression signature that captures both the presence of malignancy and the tumor's stage. This signature includes known culprits, such as IL6, as well as genes related to bone biology, hypoxia, metabolic activity, and cytomobility. We validated the capacity of this signature to identify disease and measure risk of progression in an independent gene expression profiling dataset (GSE6477) and showed a significant association with both progression-free survival (PFS) and overall survival (OS) in the CoMMpass dataset. Notably, this association remained significant when we accounted for the patient's ISS stage and the tumor's proliferative index, suggesting that this signature captures orthogonal aspects of the tumor's aggressiveness. Furthermore, by comparing malignant and normal plasma cells within each patient, we were able to identify differentially expressed genes per tumor and assess how frequently each gene is dysregulated at scale. The most common upregulated genes were the oncogene MLLT3 (rank 1), the growth factor IGF1 (rank 2), and the proteasome regulator TJP1 (rank 3). This approach provides a rationale for the prioritization of novel targets, based on their rank, and can potentially uncover clinically meaningful differences between disease stages. **Conclusions:** Our current understanding of transcriptomic alterations in patients with MGUS and SMM is based on bulk RNA-sequencing or microarray studies, which cannot distinguish between malignant and normal plasma cells, whose proportions vary across patients. This large single-cell RNA-sequencing cohort of patients with MGUS and SMM can help us gain novel insights into malignant plasma cell biology and nominate therapeutic targets for interception of progression.

Thrombotic significance in plasma cell disorders: do associated clonal hematopoiesis of indeterminate potential (CHIP) mutations increase the risk?

Ritika Vankina[1], Kaylyn Kirk[1], Katharine Hooper[1], Aswanth Reddy[2], Swarup Kumar[1]

[1]UConn Health; [2]Mercy Health

Introduction: The exact mechanisms of elevated thrombo-embolic risk in plasma cell disorders remain unclear. Whilst several factors such as therapeutic regimens, comorbid medical conditions and concurrent use of antiplatelet/anticoagulants can affect thrombotic propensity in these disease states have been reported; genomic alterations, particularly that of clonal hematopoiesis of indeterminate potential (CHIP) mutations which are somatic mutations noted to affect hematopoiesis is not well understood. Several have been linked to qualitative and quantitative platelet traits in previously described studies (Veninga et al Hematologica 2020, Vannuchhi et al, Semin Thromb Hemost 2013). We report genomic data and known thrombo-embolic events from 64 patients with plasma cell disorders within a year of their disease diagnosis or later. **Methods:** In this retrospective analysis, clinical and bone marrow based genomic data (Tempus xT® 684 gene DNA-based NGS platform) was gathered on 64 patients with a diagnosis of Monoclonal gammopathy of undetermined significance (MGUS), Multiple Myeloma (MM), Smoldering Myeloma (SM), AL amyloidosis (AMY) and Waldenstrom's Macroglobulinemia (WM). CHIP mutations with a predilection for thrombo-embolic events (12 with increased platelet count and 4 with function) were collected as described in Veninga et al 2020. Venous thrombotic events (VTE), ischemic coronary events (ICE), and cerebrovascular accidents (CVA) within one year or after disease diagnosis were also abstracted. **Results:** Twenty-two CHIP mutations were identified amongst all 64 patients. 11 being in MM, followed by WM (6), MGUS (4), SM (1), SP (0), and AMY (0). 18 of these CHIP mutations were known to increase platelet count and/or function, the most frequent ones being DNMT3A LOF (7,38.9%) and JAK2 GOF (3,16.7%). In 24 MM patients, 9 patients had a CHIP mutation which increase platelet count/function, of whom, 4 (44.4%) had a thrombo-embolic event (3 VTE and 1 ICD) whilst the frequency of thrombo-embolic events in the patients without CHIP mutations was 33.3% (5/15; 4 VTE and 1 CVA); (p 0.68, Fischer's exact test). No thrombotic events were reported in MGUS, SM, and WM patients with identified CHIP mutations and increased platelet count/function. Of all the patients in the data set regardless of the presence of a CHIP mutation, a total of 9(14%) suffered a VTE, 3 (4.7%) CVA, and 4 (6.3%) an ICE within a year of disease diagnosis. **Conclusions:** In this analysis of 64 patients, we identified a proportion of patients with CHIP mutations that affect platelet function and/or count as well as thrombo-embolic events around the time of their diagnosis or later however a clear association could not be established between them. Further studies are needed to inform of the thrombotic risk and the initiation of prophylactic anticoagulation in these disorders.

Albumin: globulin reversal as a screening tool for MGUS (targeted screening) in hospitalized setting

Uday Yanamandra[1], Abhinav Kumar[1], Anurodh Gupta[1], Bhushan Asthana[1], J Muthu Krishnan[1]

[1]Armed Forces Medical College

Introduction: There is an unmet need to discover novel targeted screening guidelines for monoclonal gammopathy of undetermined clinical significance (MGUS) in the Indian scenario which can help in early detection and diagnosis. Liver function tests (LFTs) are routinely performed in hospital settings for a variety of indications, with many having albumin-globulin (A:G) ratio reversals. We have designed this study to gauge the prevalence of MGUS in individuals above the age of 50 years with A: G ratio reversal in hospitalized settings. The objectives of the study were to measure the incidence of A: G ratio reversal in total LFT samples run in the hospital for various indications and to determine whether targeted screening of unexplained A: G ratio reversal in hospitalized patients is a fruitful strategy. **Methods:** This is a single-center, prospective observational study carried out from 01 May 2022 to 30 May 2023 at tertiary care center in Western India. All the LFTs of the admitted patients over the study period to the medical wards were included in the study. Patients with A:G reversal were subjected to detailed clinical examination and investigations to rule out non-myelomatous causes for the reversal of the ratio. Samples with unexplained A:G ratio reversal and unresolving A:G reversal despite of three months of observation were subjected to Serum Protein Electrophoresis (SPEP). Data was analysed using JMP ver. 16.0.0. **Results:** A total of 5148 LFTs were screened during the study period, of which 300 (5.82%) had A:G reversal. The median age of the study population with A:G reversal was 59 years (IQR - 14.3) with a male preponderance (59%). Etiologically amongst patients with A:G reversal 54% had infection, 15% had inflammation, 13% suffer from Chronic Liver Disease and 9% have Chronic Kidney Disease. Only 9% of patients (n-27) had no evident secondary causes, and of these 11% (n-3) have an M-spike on SPEP. Of all patients with A:G reversal, 1.1% have evidence of MGUS, all being IgG Lambda variants and none having any features of smoldering or multiple myeloma based on IMWG guidelines. **Conclusions:** A:G reversal compounded with good clinical history and examination can be an effective tool for targeted screening of MGUS. A majority of A:G reversals in hospital settings are due to secondary causes, requiring deliberate effort for exclusion.

All the LFTs of the admitted patients over the study period to the medical wards were included in the study. Patients with A:G reversal were subjected to detailed clinical examination and investigations to rule out non-myelomatous causes for the reversal of the ratio. Samples with unexplained A:G ratio reversal and unresolving A:G reversal despite of three months of observation were subjected to Serum Protein Electrophoresis (SPEP). Data was analysed using JMP ver. 16.0.0. **Results:** A total of 5148 LFTs were screened during the study period, of which 300 (5.82%) had A:G reversal. The median age of the study population with A:G reversal was 59 years (IQR - 14.3) with a male preponderance (59%). Etiologically amongst patients with A:G reversal 54% had infection, 15% had inflammation, 13% suffer from Chronic Liver Disease and 9% have Chronic Kidney Disease. Only 9% of patients (n-27) had no evident secondary causes, and of these 11% (n-3) have an M-spike on SPEP. Of all patients with A:G reversal, 1.1% have evidence of MGUS, all being IgG Lambda variants and none having any features of smoldering or multiple myeloma based on IMWG guidelines. **Conclusions:** A:G reversal compounded with good clinical history and examination can be an effective tool for targeted screening of MGUS. A majority of A:G reversals in hospital settings are due to secondary causes, requiring deliberate effort for exclusion.

Prevalence of MGUS in rural Indian population: Results of SIMPLe (IMAGe-002) study

Uday Yanamandra[1], Saurabh Bobdey[1], Celine Raphael[1], Junah Hassan[1], VK Bhatti[1], J Muthu Krishnan[1], SMILe Study Group[1]

[1]Armed Forces Medical College

Introduction: The incidence of monoclonal gammopathies is rising across the globe. Although the prevalence of monoclonal gammopathy of undetermined significance (MGUS) has been evaluated in two hospital-based studies in India, no data exists on its prevalence in community-based settings. So we aimed to determine the prevalence of MGUS in a community-based setting amongst the rural Indian population. **Methods:** A cross-sectional study was conducted in an agrarian village in India covering a perimeter of 24.76Km and 4588.3 hectares with an 89.2% population coverage for adults more than 45y spending 12096 man-hours as part of SIMPLe (Screening Intervention for Myeloma and Prevention of Lifestyle diseases) study under the aegis of Indian Myeloma Academic Groupe (IMAGe) registered vide CTRI/2023/03/051220. For the complete study population, demographic details, medical history, and blood samples were collected after a thorough medical examination. Hemogram, biochemistry (Liver and renal function tests), and serum protein electrophoresis (SPEP) were universally performed in all individuals. Serum immunofixation electrophoresis (SIFE) was performed for those with abnormal SPEP graphs (those with M spike and those with abnormal bulges in beta-2 or gamma region suspicious of MGUS). Patients with monoclonal protein on SPEP or SIFE were further assessed for any features of smoldering/ multiple myeloma. The data was analyzed using JMP ver. 16.0.0. **Results:** The prevalence of MGUS in the study population was 1.75%. The mean age of individuals with MGUS was 63.4±5.2y with male preponderance (60%). The mean Hb was 12.39±1.8g/ dL with none of the patients having any renal dysfunction. None of the patients fit into the criteria for smoldering or multiple myeloma using IMWG criteria. Among those with MGUS, the distribution of Heavy and light chains was IgG - 83.33%, IgA - 16.67% with none having IgM/ IgD paraprotein, Kappa – 50%, and Lambda – 50%. Two individuals only had light chain MGUS. **Conclusions:** Our study provides a comprehensive description of the prevalence of MGUS in a rural community setting in India. The background prevalence is much less compared to the Western (both USA ~3% and European~5%) population.

Multiple myeloma therapy in Tawam hospital: first report from United Arab Emirates

Arif Alam[1]

[1]SEHA

Introduction: Plasma cell disorders are a heterogeneous group of disease ranging from Monocloncal gammopathy of unknown significance to Multiple myeloma (MM) and the highly lethal plasma cell leukemia. The standard of care for induction has been become a triplet regimen lately. Here we describe our experience with the management of MM patients **Methods:** This is a retrospective analysis of Thirty-five patients who were seen with diagnosis with plasma cell disorders from January 1, 2016 till June 30th 2018 at our center in the UAE. Patients with solitary plasmacytoma and plasma cell leukemia were excluded from further analysis (N=3). Thirty-two patients were included in the analysis. **Results:** The median age was 58 years (range 26 to 94 years). Male to female ratio was 3:1. Biochemical classification showed ten patients with light chain disease only. Twelve patients had IgG kappa disease, eight had IgG lambda while there was one with IgA lambda disease and one was non-secretory with diffuse plasmacytomas. ISS staging (based on albumin and Beta 2 microglobulin) showed ISS stage 1=7, ISS stage 2= 13, ISS stage 3=8 and data was not available for four patients (diagnosed elsewhere). Cytogenetic risk stratification was not possible due to lack of access to interphase FISH. Seven patients did not receive any therapy either due to refusal for further investigation and therapy or poor performance status and comorbidities. Four of these seven have expired while the other three have been lost to follow-up. Twenty-four patients were given induction therapy with a Bortezomib (V)-based regimen while one received IMIDs-based treatment. Regimens and patient numbers are as follows: RVd (Lenalidomide/V/ dexamethasone) (N=16), PVd (pomalidomide instead of R due to renal insufficiency) (N=1), V/thalidomide (T) (N=1), VCd (N=2; one for secondary amyloidosis) and Vd (N=4) (poor performance status and/or comorbidities). All patients were given zoledronic acid as well as herpes zoster prophylaxis. Venous thromboembolism (VTE) prophylaxis was prescribed based on published guidelines. Response evaluation was performed in patients receiving at least four cycles of therapy: CR(N=7); Very Good Partial Remission (VGPR) (N=6); Partial Response (PR) (N=5) and not evaluable for response due to lack of data (N=7). Five patients were documented to have received autologous stem cell transplant (autoSCT). Seven patients, lost to follow up after induction presumably received an autoSCT. **Conclusions:** This is the first report on the management of MM patients in UAE. With a median follow-up of 216 days (range 3 to 839 days) the response rate to induction therapy was 72% (CR+ VGPR). We are unable to report progression free survival due to short follow-up. This response rate of 72% (VGPR or better) is less than the reported in the literature. This may partly be due to lack of patient data regarding induction therapy elsewhere, the use of double over triplet regimens and the absence of autoSCT facilities.

Clinical outcomes of older patients aged 80 and over with newly diagnosed multiple myeloma

Sung Hwa Bae[1], Sang Hwan Lee[2], Hee Jeong Cho[3], Joon Ho Moon[4], Min Kyoung kim[5], Mi Hwa Heo[6], Young Rok Do[7]

[1]Daegu Catholic University Hospital; [2]Daegu Fatima Hospital; [3]Department of Hematology-Oncology, Kyungpook National University Hospital, School of Medicine, Kyungpook National University, Daegu, South Korea; [4]Kyungpook National University Hospital; [5]Yeungnam University Hospital; [6]Dongsan Medical Center; [7]Department of Hemato-Oncology, Keimyung University Dongsan Medical Center, Daegu, South Korea

Introduction: Multiple myeloma (MM) is primarily a disease of elderly patients. Although effective novel agents and supportive care have substantially improved outcomes, geriatric patients with MM have a higher risk of early mortality and lower survival rates. In this study, we retrospectively analyzed the clinical features and survival outcomes of MM patients aged ≥80 years. **Methods:** MM patients

aged ≥80 years from 2010 to 2019 at 5 hospitals in Daegu, Korea were eligible for inclusion were enrolled. The primary endpoints of this study were overall survival and prognostic factors for overall survival. **Results:** A total of 127 patients, with a median age of 83 years (range, 80-93 years) were included in this analysis. Of these, 52 patients (40.9%) had a poor performance status (ECOG 3-4), 84 (66.1%) had an International Staging System (ISS) stage III disease, and 69 (54.3%) had a Charlson comorbidity index score of 2 or more. Chemotherapy was given to 86 patients (67.7%). The median overall survival of all patients was 13.8 months. Thirty-four patients (26.8%) died within 3 months of MM diagnosis. In the univariate analysis, prognostic factors for overall survival were age (80-83 vs. >83, p=0.017), ECOG performance status (0-2 vs. 3,4, p< 0.001), ISS stage (I, II vs. III, p=0.005), hypercalcemia (p=0.007), thrombocytopenia (p=0.007) and treatment (chemotherapy vs. best supportive care, p< 0.001). In multivariate analyses, overall survival was affected by ECOG performance status, ISS stage, and chemotherapy treatment. **Conclusions:** Some elderly MM patients aged ≥80 years exhibit very poor prognosis, highlighting the need to effectively distinguish such patients and develop appropriate best supportive care for them.

P-107

The second revision of international staging system (R2-ISS) in newly diagnosed multiple myeloma patients: RWE settings

Aleksandra Sretenovic[1,2], Marko Mitrovic[1], Nikola Vukosavljevic[3], Natalija Kecman[1], Jelica Jovanovic[1], Zoran Bukumiric[4], Jelena Bila[1,2]

[1]Clinic of Hematology University Clinical Centre of Serbia; [2]Medical faculty, Univeristy of Belgrade; [3]Clinical Hospital Center "Zvezdara"; [4]Institute for Medical Statistics and Informatics, Medical faculty, Univeristy of Belgrade

Introduction: The recent introduction of R2-ISS scoring system brought better risk stratification of patients (pts) with newly diagnosed multiple myeloma (NDMM). The aim of study was to analyze prognostic significance of R2-ISS score in NDMM pts within RWE settings. **Methods:** Analyzed group included 247 transplant ineligible NDMM pts, diagnosed during period 2017-2021 (128 male; 119 female, mean age 63 yrs, range 37-82). The IgG myeloma was diagnosed in 149pts (60.3%), IgA in 50 (20.2%), BJ in 48 (19.4%), non-secretory MM in 3pts (1.2%). Renal impairment was present in 73pts (29.6%). Double and triple hit MM was observed in 16pts (7.5%). Stratification according to Revised-ISS (R-ISS) score was as follows: R-ISS1 in 61pts (24.7%), R-ISS2 in 160pts (64.8%), while R-ISS3 was present in 26pts (10.5%). Treatment with Thalidomide (Thal) based triplets was applied in 82pts (33.2%), while 165pts (66.8%) were treated with Bortezomib (Bz) based triplet combinations. **Results:** According to newly presented R2-ISS score, low risk MM had 61pts (R2-ISS 1 24.7%), intermediate-low 56pts (R2-ISS 2 22.7%), intermediate-high 116pts (R2-ISS 3 47%), and high-risk had 14pts (R2-ISS 4 5.7%). Overall response rate (ORR ≥PR) was achieved in 215pts (87.04%). Finding of double and triple hit MM was characterized with significantly shorter PFS (Log Rank 6.37, p=0.012) and OS (Log Rank 6.57, p=0.010), compared to standard risk pts. Patients with R2-ISS 1 score had median PFS 46 months (range: 41.2-51.8m), R2-ISS 2 group had 38.5m (range: 33.6-43.4m), R2-ISS 3 36.9m (range: 29.7-44.2m) and R2-ISS 4 group had the shortest PFS, 28.8m (range: 12.9-44.7m). Median OS was as follows: R2-ISS 1 55.4m (range: 51.6-59.3m), R2-ISS 2 44.2m (range: 39.9-48.5m), R2-ISS 3 41.5m (range: 35.3-47.7m), R2-ISS 4 29.2m (range: 16.2-42.2m). There was a significant difference in OS according to R2-ISS score (log rank=19.52, p<0.001). Although a higher R2-ISS score was associated with shorter PFS, statistical significance was not proved among different R2-ISS groups (log rank=7.41, p=0.060). Still, R2-ISS 4 score had the worst prognosis regarding PFS (Log Rank 9.60, p=0.002) and OS (Log Rank 13.86, p=0.000) in comparison to pts with lower risk scores. The multivariate analysis of following variables: age, elevated LDH, double and triple hit MM, R-ISS and R2-ISS score, pointed out the most pronounced poor prognostic impact to PFS of R2-ISS 4 score (HR 5.07, 95% CI 1.37-18.8). Similarly, OS was also influenced by the presence of high-risk R2-ISS score 4 (HR 6.53, 95% CI 1.81-23.54). **Conclusions:** Newly presented R2-ISS score is applicable and powerful prognostic tool, more sensitive in comparison to classic R-ISS score, thus better identifying MM pts with high risk features.

Unravelling transplant-ineligible newly diagnosed multiple myeloma treatment in real-world practice in Spain: CARINAE study

Maria Casanova Espinosa[1], Miguel Teodoro Hernandez Garcia[2], Juan Alfons Soler Campos[3], Susana Herráez Rodriguez[4], Maria José Moreno Belmonte[5], Miriam González-Pardo[6], Mercedes Gironella Mesa[7], Felipe de Arriba de la Fuente[8]

[1]Hospital Costa del Sol, Marbella (Málaga), Spain; [2]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain.; [3]Consorci Corporació Sanitària Parc Taulí de Sabadell, Cataluña, Spain; [4]Hospital Universitario Basurto, Bizcaia, Spain; [5]Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain; [6]Janssen-Cilag SA Spain; [7]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [8]Hospital General Universitario Morales Meseguer, Murcia, Spain

Introduction: There is few data regarding real-world treatment patterns and outcomes of transplant-ineligible newly diagnosed multiple myeloma patients (TIE-NDMM) in Spain. In recent years, several treatment regimens have been authorized as effective options for TIE-NDMM, providing patients better outcomes and quality of life, as evidenced in clinical trials. However, the contribution of incorporating these new treatments into daily therapeutic arsenal has not been widely explored. **Methods:** Observational, ambispective, multicenter ongoing study on TIE-NDMM patients who started antineoplastic treatment in the context of daily clinical practice in Spanish hospitals. Group A: started treatment with a combination of ≥2 drugs, between Sep/01/2018 and Aug/31/19. Group B: started treatment with daratumumab in combination

aged ≥80 years from 2010 to 2019 at 5 hospitals in Daegu, Korea were eligible for inclusion were enrolled. The primary endpoints of this study were overall survival and prognostic factors for overall survival. **Results:** A total of 127 patients, with a median age of 83 years (range, 80-93 years) were included in this analysis. Of these, 52 patients (40.9%) had a poor performance status (ECOG 3-4), 84 (66.1%) had an International Staging System (ISS) stage III disease, and 69 (54.3%) had a Charlson comorbidity index score of 2 or more. Chemotherapy was given to 86 patients (67.7%). The median overall survival of all patients was 13.8 months. Thirty-four patients (26.8%) died within 3 months of MM diagnosis. In the univariate analysis, prognostic factors for overall survival were age (80-83 vs. >83, p=0.017), ECOG performance status (0-2 vs. 3,4, p< 0.001), ISS stage (I, II vs. III, p=0.005), hypercalcemia (p=0.007), thrombocytopenia (p=0.007) and treatment (chemotherapy vs. best supportive care, p< 0.001). In multivariate analyses, overall survival was affected by ECOG performance status, ISS stage, and chemotherapy treatment. **Conclusions:** Some elderly MM patients aged ≥80 years exhibit very poor prognosis, highlighting the need to effectively distinguish such patients and develop appropriate best supportive care for them.

Treatment with Thalidomide (Thal) based triplets was applied in 82pts (33.2%), while 165pts (66.8%) were treated with Bortezomib (Bz) based triplet combinations. **Results:** According to newly presented R2-ISS score, low risk MM had 61pts (R2-ISS 1 24.7%), intermediate-low 56pts (R2-ISS 2 22.7%), intermediate-high 116pts (R2-ISS 3 47%), and high-risk had 14pts (R2-ISS 4 5.7%). Overall response rate (ORR ≥PR) was achieved in 215pts (87.04%). Finding of double and triple hit MM was characterized with significantly shorter PFS (Log Rank 6.37, p=0.012) and OS (Log Rank 6.57, p=0.010), compared to standard risk pts. Patients with R2-ISS 1 score had median PFS 46 months (range: 41.2-51.8m), R2-ISS 2 group had 38.5m (range: 33.6-43.4m), R2-ISS 3 36.9m (range: 29.7-44.2m) and R2-ISS 4 group had the shortest PFS, 28.8m (range: 12.9-44.7m). Median OS was as follows: R2-ISS 1 55.4m (range: 51.6-59.3m), R2-ISS 2 44.2m (range: 39.9-48.5m), R2-ISS 3 41.5m (range: 35.3-47.7m), R2-ISS 4 29.2m (range: 16.2-42.2m). There was a significant difference in OS according to R2-ISS score (log rank=19.52, p<0.001). Although a higher R2-ISS score was associated with shorter PFS, statistical significance was not proved among different R2-ISS groups (log rank=7.41, p=0.060). Still, R2-ISS 4 score had the worst prognosis regarding PFS (Log Rank 9.60, p=0.002) and OS (Log Rank 13.86, p=0.000) in comparison to pts with lower risk scores. The multivariate analysis of following variables: age, elevated LDH, double and triple hit MM, R-ISS and R2-ISS score, pointed out the most pronounced poor prognostic impact to PFS of R2-ISS 4 score (HR 5.07, 95% CI 1.37-18.8). Similarly, OS was also influenced by the presence of high-risk R2-ISS score 4 (HR 6.53, 95% CI 1.81-23.54). **Conclusions:** Newly presented R2-ISS score is applicable and powerful prognostic tool, more sensitive in comparison to classic R-ISS score, thus better identifying MM pts with high risk features.

Unravelling transplant-ineligible newly diagnosed multiple myeloma treatment in real-world practice in Spain: CARINAE study

Maria Casanova Espinosa[1], Miguel Teodoro Hernandez Garcia[2], Juan Alfons Soler Campos[3], Susana Herráez Rodriguez[4], Maria José Moreno Belmonte[5], Miriam González-Pardo[6], Mercedes Gironella Mesa[7], Felipe de Arriba de la Fuente[8]

[1]Hospital Costa del Sol, Marbella (Málaga), Spain; [2]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain.; [3]Consorci Corporació Sanitària Parc Taulí de Sabadell, Cataluña, Spain; [4]Hospital Universitario Basurto, Bizcaia, Spain; [5]Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain; [6]Janssen-Cilag SA Spain; [7]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [8]Hospital General Universitario Morales Meseguer, Murcia, Spain

Introduction: There is few data regarding real-world treatment patterns and outcomes of transplant-ineligible newly diagnosed multiple myeloma patients (TIE-NDMM) in Spain. In recent years, several treatment regimens have been authorized as effective options for TIE-NDMM, providing patients better outcomes and quality of life, as evidenced in clinical trials. However, the contribution of incorporating these new treatments into daily therapeutic arsenal has not been widely explored. **Methods:** Observational, ambispective, multicenter ongoing study on TIE-NDMM patients who started antineoplastic treatment in the context of daily clinical practice in Spanish hospitals. Group A: started treatment with a combination of ≥2 drugs, between Sep/01/2018 and Aug/31/19. Group B: started treatment with daratumumab in combination

aged ≥80 years from 2010 to 2019 at 5 hospitals in Daegu, Korea were eligible for inclusion were enrolled. The primary endpoints of this study were overall survival and prognostic factors for overall survival. **Results:** A total of 127 patients, with a median age of 83 years (range, 80-93 years) were included in this analysis. Of these, 52 patients (40.9%) had a poor performance status (ECOG 3-4), 84 (66.1%) had an International Staging System (ISS) stage III disease, and 69 (54.3%) had a Charlson comorbidity index score of 2 or more. Chemotherapy was given to 86 patients (67.7%). The median overall survival of all patients was 13.8 months. Thirty-four patients (26.8%) died within 3 months of MM diagnosis. In the univariate analysis, prognostic factors for overall survival were age (80-83 vs. >83, p=0.017), ECOG performance status (0-2 vs. 3,4, p< 0.001), ISS stage (I, II vs. III, p=0.005), hypercalcemia (p=0.007), thrombocytopenia (p=0.007) and treatment (chemotherapy vs. best supportive care, p< 0.001). In multivariate analyses, overall survival was affected by ECOG performance status, ISS stage, and chemotherapy treatment. **Conclusions:** Some elderly MM patients aged ≥80 years exhibit very poor prognosis, highlighting the need to effectively distinguish such patients and develop appropriate best supportive care for them.

The second revision of international staging system (R2-ISS) in newly diagnosed multiple myeloma patients: RWE settings

Aleksandra Sretenovic[1,2], Marko Mitrovic[1], Nikola Vukosavljevic[3], Natalija Kecman[1], Jelica Jovanovic[1], Zoran Bukumiric[4], Jelena Bila[1,2]

[1]Clinic of Hematology University Clinical Centre of Serbia; [2]Medical faculty, Univeristy of Belgrade; [3]Clinical Hospital Center "Zvezdara"; [4]Institute for Medical Statistics and Informatics, Medical faculty, Univeristy of Belgrade

Introduction: The recent introduction of R2-ISS scoring system brought better risk stratification of patients (pts) with newly diagnosed multiple myeloma (NDMM). The aim of study was to analyze prognostic significance of R2-ISS score in NDMM pts within RWE settings. **Methods:** Analyzed group included 247 transplant ineligible NDMM pts, diagnosed during period 2017-2021 (128 male; 119 female, mean age 63 yrs, range 37-82). The IgG myeloma was diagnosed in 149pts (60.3%), IgA in 50 (20.2%), BJ in 48 (19.4%), non-secretory MM in 3pts (1.2%). Renal impairment was present in 73pts (29.6%). Double and triple hit MM was observed in 16pts (7.5%). Stratification according to Revised-ISS (R-ISS) score was as follows: R-ISS1 in 61pts (24.7%), R-ISS2 in 160pts (64.8%), while R-ISS3 was present in 26pts (10.5%). Treatment with Thalidomide (Thal) based triplets was applied in 82pts (33.2%), while 165pts (66.8%) were treated with Bortezomib (Bz) based triplet combinations. **Results:** According to newly presented R2-ISS score, low risk MM had 61pts (R2-ISS 1 24.7%), intermediate-low 56pts (R2-ISS 2 22.7%), intermediate-high 116pts (R2-ISS 3 47%), and high-risk had 14pts (R2-ISS 4 5.7%). Overall response rate (ORR ≥PR) was achieved in 215pts (87.04%). Finding of double and triple hit MM was characterized with significantly shorter PFS (Log Rank 6.37, p=0.012) and OS (Log Rank 6.57, p=0.010), compared to standard risk pts. Patients with R2-ISS 1 score had median PFS 46 months (range: 41.2-51.8m), R2-ISS 2 group had 38.5m (range: 33.6-43.4m), R2-ISS 3 36.9m (range: 29.7-44.2m) and R2-ISS 4 group had the shortest PFS, 28.8m (range: 12.9-44.7m). Median OS was as follows: R2-ISS 1 55.4m (range: 51.6-59.3m), R2-ISS 2 44.2m (range: 39.9-48.5m), R2-ISS 3 41.5m (range: 35.3-47.7m), R2-ISS 4 29.2m (range: 16.2-42.2m). There was a significant difference in OS according to R2-ISS score (log rank=19.52, p<0.001). Although a higher R2-ISS score was associated with shorter PFS, statistical significance was not proved among different R2-ISS groups (log rank=7.41, p=0.060). Still, R2-ISS 4 score had the worst prognosis regarding PFS (Log Rank 9.60, p=0.002) and OS (Log Rank 13.86, p=0.000) in comparison to pts with lower risk scores. The multivariate analysis of following variables: age, elevated LDH, double and triple hit MM, R-ISS and R2-ISS score, pointed out the most pronounced poor prognostic impact to PFS of R2-ISS 4 score (HR 5.07, 95% CI 1.37-18.8). Similarly, OS was also influenced by the presence of high-risk R2-ISS score 4 (HR 6.53, 95% CI 1.81-23.54). **Conclusions:** Newly presented R2-ISS score is applicable and powerful prognostic tool, more sensitive in comparison to classic R-ISS score, thus better identifying MM pts with high risk features.

Introduction: There is few data regarding real-world treatment patterns and outcomes of transplant-ineligible newly diagnosed multiple myeloma patients (TIE-NDMM) in Spain. In recent years, several treatment regimens have been authorized as effective options for TIE-NDMM, providing patients better outcomes and quality of life, as evidenced in clinical trials. However, the contribution of incorporating these new treatments into daily therapeutic arsenal has not been widely explored. **Methods:** Observational, ambispective, multicenter ongoing study on TIE-NDMM patients who started antineoplastic treatment in the context of daily clinical practice in Spanish hospitals. Group A: started treatment with a combination of ≥2 drugs, between Sep/01/2018 and Aug/31/19. Group B: started treatment with daratumumab in combination

with bortezomib, melphalan and prednisone (DVMP group), between Sep/01/19 and Nov/30/20. Here, we present the efficacy and safety outcomes obtained in the second interim analysis after ≈24-month study initiation. **Results:** 117 patients recruited, 108 evaluable for efficacy in this interim analysis (group A n=51; group B n=57). No significant differences were observed in basal clinical and demographics characteristics between groups: mean age 76.9 years; male (53.7%); cardiopathy 28.7%; renal failure 25%; pulmonary obstructive disease 8.3%; peripheral neuropathy 2.8%; median ECOG PS 1; most common myeloma type was IgG (49.5%); 13.9% had a high risk cytogenetic profile, defined by one of the following alterations: t(4;14), t(14;16) and del 17p13; plasmacytoma 24.3 %. More than 90% of the patients in group A started treatment with schemes based on bortezomib, lenalidomide, or both. Median follow-up was 36.3 versus 23.3 months for group A and B, respectively, since initiation of first-line treatment (p< 0,0001). Probably in relation to the different follow-up, the median PFS for Group A was 32.78 months and not reached for Group B (p=0,1129). The progression rate at 18-months was 27.5% and 10.5% for Group A and B respectively (p=0,0238). Rates of ≥VGPR and ≥CR, were 60% and 30% in Group A whilst 75.4% and 33.3% in Group B. 36.9% of the patients showed adverse drug reactions (ADR) related to the first-line treatment during the prospective period. 10.6% of the reported ADRs were serious with no significant differences between groups. No unexpected ADRs were observed. Additional data will be presented at the Congress. **Conclusions:** In this interim analysis, a significant clinical benefit has been identified in patients treated with DVMP, with improved PFS indicators vs. other treatment alternatives. Along with the deeper hematological responses observed, we expect this benefit to be consolidated in the final PFS analysis of the Carinae study. These real-world practice data continue to support the choice of daratumumab regimens in frontline TIE-NDMM patients.

Introduction: Trial in Progress (TiP). Prior to the recent introduction of daratumumab (Dara) in the frontline setting, lenalidomide-dexamethasone (Rd) has represented a standard of care for transplant-ineligible (NTE) patients (pts) with newly diagnosed multiple myeloma (NDMM). Nonetheless, median progression-free survival (PFS) with Rd was still limited, as compared with 3/4-drug regimens, also including carfilzomib (K). The randomized, multicenter phase III EMN20 trial (NCT04096066) compares KRd vs Rd in fit/intermediate-fit NDMM pts according to the International Myeloma Working Group frailty score. **Methods:** NTE NDMM pts were randomized to KRd (28-day cycles, once-weekly K 56 mg/m² on days 1,8,15 for 12 cycles and on days 1,15 from cycle 13 onwards, R 25 mg orally on days 1-21 and d 40 mg on days 1,8,15,22) or continuous Rd (28-day cycles, R 25 mg on days 1-21, d 40 mg on days 1,8,15,22). Pt stratification was based on International Staging System (ISS) stage and fitness status. After 5 years, pts in the KRd arm will stop K administration and continue Rd, except for pts achieving sustained minimal residual disease (MRD) negativity after 2 years, who will stop K administration after 2 years and continue Rd. The primary endpoints were MRD after 2 years of treatment and PFS. For MRD assessment, the clonoSEQ® assay was used at the sensitivity of $\geq 10^{-5}$. The MRD negativity rate was the proportion of MRD-negative pts (sensitivity $\geq 10^{-5}$) at 2 years of treatment. Key secondary endpoints included response rates, overall survival and safety. On Nov 23, 2021, the protocol was prematurely stopped after the introduction of frontline Dara-Rd. Here we report the demographics of the enrolled pts. **Results:** A total of 101 pts were enrolled and 82 were randomized (KRd 42

with bortezomib, melphalan and prednisone (DVMP group), between Sep/01/19 and Nov/30/20. Here, we present the efficacy and safety outcomes obtained in the second interim analysis after ≈24-month study initiation. **Results:** 117 patients recruited, 108 evaluable for efficacy in this interim analysis (group A n=51; group B n=57). The randomized, multicenter phase III EMN20 trial (NCT04096066) compares KRd vs Rd in fit/intermediate-fit NDMM pts according to the International Myeloma Working Group frailty score. **Methods:** NTE NDMM pts were randomized to KRd (28-day cycles, once-weekly K 56 mg/m² on days 1,8,15 for 12 cycles and on days 1,15 from cycle 13 onwards, R 25 mg orally on days 1-21 and d 40 mg on days 1,8,15,22) or continuous Rd (28-day cycles, R 25 mg on days 1-21, d 40 mg on days 1,8,15,22). Pt stratification was based on International Staging System (ISS) stage and fitness status. After 5 years, pts in the KRd arm will stop K administration and continue Rd, except for pts achieving sustained minimal residual disease (MRD) negativity after 2 years, who will stop K administration after 2 years and continue Rd. The primary endpoints were MRD after 2 years of treatment and PFS. For MRD assessment, the clonoSEQ® assay was used at the sensitivity of $\geq 10^{-5}$. The MRD negativity rate was the proportion of MRD-negative pts (sensitivity $\geq 10^{-5}$) at 2 years of treatment. Key secondary endpoints included response rates, overall survival and safety. On Nov 23, 2021, the protocol was prematurely stopped after the introduction of frontline Dara-Rd. Here we report the demographics of the enrolled pts. **Results:** A total of 101 pts were enrolled and 82 were randomized (KRd 42

vs Rd 40); 19 pts were not randomized due to screening failure (17) and withdrawal of consent (2). Pt characteristics were well balanced between the KRd and Rd arms: median age was 73 (interquartile range [IQR] 70–76) and 74 years (IQR 72–76), 60% vs 58% of pts were fit, 40% vs 42% were intermediate fit, 33% vs 30% had ISS stage III disease, 17% vs 8% had Revised ISS III, 10% vs 3% had Eastern Cooperative Oncology Group (ECOG) Performance Status 2 and 22% vs 22% had high-risk cytogenetics, respectively. Median follow-up was 23 months (IQR 19–28). In the KRd vs Rd arms, 33/42 (78.6%) vs 19/40 (47.5%) pts are still under treatment; reasons for discontinuation were medical decision (1 vs 4), death (2 vs 4), adverse events (2 vs 1), progressive disease (3 vs 10), lost to follow-up (1 vs 0) and consent withdrawal (0 vs 2). The analysis of the primary MRD endpoint is planned for Q4 of 2023, after all pts have received 2 years of treatment. **Conclusions:** Data about MRD will be presented at the meeting.

Introduction: The double-blind TOURMALINE-MM4 study (NCT02312258) included patients (pts) with newly diagnosed multiple myeloma (NDMM) who were ineligible for autologous stem cell transplantation (ASCT; Dimopoulos, J Clin Oncol 2020). The study previously demonstrated a statistically significant and clinically meaningful improvement in its primary endpoint of progression-free survival (PFS) for ixazomib (ixa) vs placebo (pbo) maintenance. An interim analysis showed no statistically significant difference in the key secondary endpoint of overall survival (OS; Dimopoulos, ASH 2021). We present the final OS analysis. **Methods:** Full methods have been published previously (Dimopoulos, J Clin Oncol 2020). Eligible pts were randomized to receive single agent ixa (n=425) or pbo maintenance (n=281) for up to twenty-six 28-day cycles, or until progressive disease (PD) or unacceptable toxicity. **Results:** At data cut (Oct 29, 2022), median follow-up for ixa vs pbo was 57 vs 58 months, OS events had occurred in 43 vs 41% of pts, and median OS was 65 vs 70 months (not statistically significant; hazard ratio [HR] 1.090; 95% confidence interval [CI] 0.861–1.381). There were no significant differences in median OS for ixa vs pbo among pts aged ≥75 years at randomization (55 vs 70 months; HR 1.317; 95% CI 0.909–1.909), frail pts (56 vs 44 months; HR 0.975; 95% CI 0.613–1.549), and pts with baseline high-risk cytogenetics [del(17p) and/or t(4;14) and/or t(14;16); 37 vs 48 months; HR 1.357; 95% CI 0.799–2.306]. Median PFS2 (PFS on next-line therapy) for ixa vs pbo was 51 vs 50 months (not significant; HR 0.984; 95% CI 0.777–1.246); median time to next therapy was 22 vs 17 months (not significant; HR 0.881; 95% CI 0.734–1.058). For ixa vs pbo, 72% of pts in each arm received ≥1 subsequent anti-cancer therapy, including: corticosteroids (67 vs 67%); immunomodulatory drugs (60 vs 61%); proteasome inhibitors (PI; 34 vs 36%); and monoclonal antibodies (26 vs 26%). The incidence of new primary malignancies (NPMs) in each treatment arm was 3%, with < 1% incidence of hematological NPMs in either arm; no new safety signals were identified. **Conclusions:** The final OS analysis for TOURMALINE-MM4 showed no statistically significant difference between ixa and pbo, including among high-risk pts, despite the study meeting its primary endpoint. However, showing an OS advantage in myeloma trials is becoming increasingly difficult due to confounding effects of expanding numbers of effective treatment options with novel mechanisms of action for subsequent therapies, and imbalances in these therapies between treatment arms. Notably, due to the double-blind study design, following progression, 34% of pts who received ixa received another PI to which they were likely already refractory. Ixa had a tolerable safety profile and NPM incidence remained low. In the appropriate setting, ixa could be a viable alternative for non-ASCT NDMM pts who are refractory to common maintenance options such as lenalidomide.

vs Rd 40); 19 pts were not randomized due to screening failure (17) and withdrawal of consent (2). Pt characteristics were well balanced between the KRd and Rd arms: median age was 73 (interquartile range [IQR] 70–76) and 74 years (IQR 72–76), 60% vs 58% of pts were fit, 40% vs 42% were intermediate fit, 33% vs 30% had ISS stage III disease, 17% vs 8% had Revised ISS III, 10% vs 3% had Eastern Cooperative Oncology Group (ECOG) Performance Status 2 and 22% vs 22% had high-risk cytogenetics, respectively. Median follow-up was 23 months (IQR 19–28). In the KRd vs Rd arms, 33/42 (78.6%) vs 19/40 (47.5%) pts are still under treatment; reasons for discontinuation were medical decision (1 vs 4), death (2 vs 4), adverse events (2 vs 1), progressive disease (3 vs 10), lost to follow-up (1 vs 0) and consent withdrawal (0 vs 2). The analysis of the primary MRD endpoint is planned for Q4 of 2023, after all pts have received 2 years of treatment. **Conclusions:** Data about MRD will be presented at the meeting.

Introduction: The double-blind TOURMALINE-MM4 study (NCT02312258) included patients (pts) with newly diagnosed multiple myeloma (NDMM) who were ineligible for autologous stem cell transplantation (ASCT; Dimopoulos, J Clin Oncol 2020). The study previously demonstrated a statistically significant and clinically meaningful improvement in its primary endpoint of progression-free survival (PFS) for ixazomib (ixa) vs placebo (pbo) maintenance. An interim analysis showed no statistically significant difference in the key secondary endpoint of overall survival (OS; Dimopoulos, ASH 2021). We present the final OS analysis. **Methods:** Full methods have been published previously (Dimopoulos, J Clin Oncol 2020). Eligible pts were randomized to receive single agent ixa (n=425) or pbo maintenance (n=281) for up to twenty-six 28-day cycles, or until progressive disease (PD) or unacceptable toxicity. **Results:** At data cut (Oct 29, 2022), median follow-up for ixa vs pbo was 57 vs 58 months, OS events had occurred in 43 vs 41% of pts, and median OS was 65 vs 70 months (not statistically significant; hazard ratio [HR] 1.090; 95% confidence interval [CI] 0.861–1.381). [1]UT Southwestern Medical Center; [2]Cellular Therapy and Hematologic Malignancies Program, Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX, USA

Introduction: Multiple myeloma (MM) typically affects older adults, with a median age of diagnosis of 70 years, but 10-15% of MM patients are diagnosed at 55 years or younger. Stem cell transplant (SCT) is generally considered the standard of care for young patients with good functional status. However, little is known about the outcomes for young and fit MM patients who are unable to receive transplant due to financial status or insurance coverage. This study assesses the clinical characteristics of young transplant-eligible (TE) MM patients and compares outcomes between those who are transplant accessible (TE/TA) and transplant inaccessible (TE/TI). **Methods:** This retrospective study includes 186 patients diagnosed with MM between 18-55 years from 1997-2022 at a safety net hospital in Dallas, TX. A total of 450 patients of all ages were diagnosed with MM during this period. Patients with smoldering MM, MGUS and solitary plasmacytoma were excluded. Demographics, baseline myeloma markers, comorbidities and treatments were collected from the EHR. Outcomes were analyzed by transplant status and overall survival (OS). **Results:** Our cohort showed a high percentage of young multiple myeloma patients (41.3%) diagnosed at 55 years or younger. The median age of diagnosis was 49 years. This population consisted of 48.4% Hispanics and 33.9% African Americans as well 24.2% undocumented immigrants. There were 22 patients with ISS/R-ISS stage I disease at diagnosis (11.8%), 37 with stage II (19.9%) and 55 with stage III (29.6%). Approximately 72% of the cohort had lytic lesions. The most common first line therapies were VD (21.5%), VRD (19.4%), and CyBorD (9.7%). Other regimens such as RD, TD, and DRD made up the remainder. There was a total of 46 patients who received SCT (24.7%) (TE/TA). Both TE/TA and TE/TI relied on taxpayer funded charity assistance programs, with 75.0% and 62.5% respectively who cited this as their primary insurance coverage. Median OS, including TE/TA and TE/TI, was 7.83 years. There was a significant association with SCT access and OS (HR 0.24, 95% CI 0.11 to 0.50, p< 0.001). The mOS for TE/TA was 18.5 years with a 5-year OS rate of 94.4% (CI 86.7% to 100%), while the mOS for TE/TI was 6.60 years with a 5-year OS rate of 55.8% (CI 45.7% to 65.9%). In stage 3 disease, mOS for TE/TA and TE/TI was 7.82 versus 3.80 (HR 0.27, CI 0.10 to 0.73, p=0.002). Of the entire cohort, 36.6% were deceased at the time of data collection and 21.5% were lost to follow up at the time of data analysis. **Conclusions:** Accessibility to stem cell transplant remains a significant barrier in patients with hematologic malignancies who face financial and healthcare disparities. Our results show that MM patients who are transplant eligible but inaccessible (TE/TI) have worse OS compared to transplant accessible (TE/TA) patients.

Introduction: Older patients with multiple myeloma (MM) often present with multiple other comorbid conditions (multimorbidity) in addition to their MM. Due to the strict exclusion criteria of clinical trials, the nature and impact of these chronic conditions alongside myeloma treatment and measures of disease risk are not well-understood. Here, we used artificial intelligence and machine learning (AI/ML) methods to understand the incremental impact of multimorbidity on overall survival of MM patients as compared to MM disease characteristics alone. **Methods:** We analyzed the impact of multimorbidity on prognosis using U.S. Veterans Affairs (VA) electronic health record and cancer registry data from the 132 VA Medical Centers that treat veterans with cancer. We included all veterans aged 65+ with newly diagnosed MM initiating treatment at VA between 2004 and 2020. We measured pretreatment predictors including sociodemographic variables, MM disease parameters, labs, and treatment. We further measured 33 comorbidities tracked by the CMS Chronic Conditions Data Warehouse, as well as the prescription of 15 clinically-important classes of chronic medication. We trained random forest AI/ML models to predict three-year mortality using 3/4 of the population and validated the best-performing model on the remaining 1/4. Model performance was evaluated using area under the receiver operating characteristic curve (AUC, higher numbers = better discrimination) to measure discrimination and the Brier score to measure calibration (lower numbers = better calibration). Final model performance was compared between models containing MM-specific predictors and models containing all comorbidities and medications in addition to MM-specific predictors. **Results:** We identified 4416 patients with a median age of 74 years (interquartile range [IQR] 69-80) meeting the inclusion criteria. Median number of chronic conditions per patient was 8 (IQR 6-10), and median number of different drug classes per patient was 5 (IQR 3-7). The final model built using only MM-specific predictors demonstrated poor predictive performance (AUC 0.65, Brier score 0.23). The final model built using comorbidities and medications in addition

Introduction: Older patients with multiple myeloma (MM) often present with multiple other comorbid conditions (multimorbidity) in addition to their MM. Due to the strict exclusion criteria of clinical trials, the nature and impact of these chronic conditions alongside myeloma treatment and measures of disease risk are not well-understood. Here, we used artificial intelligence and machine learning (AI/ML) methods to understand the incremental impact of multimorbidity on overall survival of MM patients as compared to MM disease characteristics alone. **Methods:** We analyzed the impact of multimorbidity on prognosis using U.S. Veterans Affairs (VA) electronic health record and cancer registry data from the 132 VA Medical Centers that treat veterans with cancer. We included all veterans aged 65+ with newly diagnosed MM initiating treatment at VA between 2004 and 2020. We measured pretreatment predictors including sociodemographic variables, MM disease parameters, labs, and treatment. We further measured 33 comorbidities tracked by the CMS Chronic Conditions Data Warehouse, as well as the prescription of 15 clinically-important classes of chronic medication. We trained random forest AI/ML models to predict three-year mortality using 3/4 of the population and validated the best-performing model on the remaining 1/4. Model performance was evaluated using area under the receiver operating characteristic curve (AUC, higher numbers = better discrimination) to measure discrimination and the Brier score to measure calibration (lower numbers = better calibration). Final model performance was compared between models containing MM-specific predictors and models containing all comorbidities and medications in addition to MM-specific predictors. **Results:** We identified 4416 patients with a median age of 74 years (interquartile range [IQR] 69-80) meeting the inclusion criteria. Median number of chronic conditions per patient was 8 (IQR 6-10), and median number of different drug classes per patient was 5 (IQR 3-7). The final model built using only MM-specific predictors demonstrated poor predictive performance (AUC 0.65, Brier score 0.23). The final model built using comorbidities and medications in addition

to MM-specific predictors demonstrated superior predictive performance (AUC 0.87, Brier score 0.15). Being prescribed a diuretic, a beta-blocker, an opioid, or having chronic kidney disease were among the top predictors contributing to mortality risk. **Conclusions:** Our findings in a real-world population of older adults with MM initiating treatment highlight that including information on multimorbidity alongside MM-specific information yields far superior prediction of mortality compared to a focus only on MM-specific information. Further investigation into the disease-disease, disease-drug, and drug-drug interactions that mediate this risk will yield important clinical insights into the mechanisms of mortality in patients treated outside of clinical trials.

Clinical consensus on first-line (1L) treatments for transplant-ineligible (TIE) patients with newly diagnosed multiple myeloma (NDMM): delphi panel of US hematologists and oncologists

Rafael Fonseca[1], Adriana Rossi[2], Jennifer Voelker[3], Trevor Homan[3], Shuchita Kaila[3], Rohan Medhekar[3], Jessica Wilcock[4], Anna Karakusevic[4], James Cochrane[4], Daisy Bridge[4], Richard Perry[4], Faith Davies[5]

[1]Division of Hematology/Oncology, Mayo Clinic, Phoenix, AZ, USA; [2]Icahn School of Medicine, Mount Sinai, New York, NY, USA; [3]Janssen Scientific Affairs, LLC, Horsham, PA, USA; [4]Adelphi Values PROVE, Bollington, UK; [5]Perlmutter Cancer Center, NYU Langone Health, New York, NY, USA

Introduction: In the past decade, the treatment of transplant ineligible (TIE) patients with newly diagnosed multiple myeloma (NDMM) has evolved significantly. However, despite established guidelines there is a lack of uniformity in prescribing patterns. Triplets are still reserved for later lines, while monotherapy and doublets with inferior efficacy are routinely prescribed as 1L therapy, leading to a missed opportunity to attain the best long-term outcomes. Moreover, guidelines do not offer definitive recommendations on anti–CD38- vs proteasome inhibitor-based triplets in 1L, and there are no head-to-head (H2H) trials comparing these regimens which could aid in decision making. To address this knowledge gap, this study sought to gather clinical consensus from a panel of multiple myeloma (MM) experts on factors impacting 1L prescribing, challenges with existing therapies, optimal duration of therapy (DoT), and treatment decision making for TIE NDMM. **Methods:** A modified Delphi Panel with 2 online survey rounds and a virtual consensus meeting was used. US-based hematologists/oncologists who treat TIE NDMM patients were selected as expert panelists. To reach consensus, ≥80% of panelists had to rate their agreement/disagreement within a 3-point range on either end of 9-point Likert scale. The panel was double blinded to maintain the validity of the study and to prevent bias. **Results:** Eighteen experts with an average of 18.8 years in practice (119.7 MM appointments/month; 104.7 patients with MM/month) completed both surveys; 9 of them participated in the consensus meeting. Consensus was reached that, in addition to the treatment's effects on progression-free survival (PFS), overall survival (OS), and its adverse event profile, frailty (89%), poor ECOG score (83%), and comorbidities (89%) have a strong impact on treatment selection. All panelists concurred that it is important to always or in most cases use the most effective regimen (one that best improved PFS and OS) as 1L therapy. Sixteen (89%) panelists considered one regimen to be more efficacious than other regimens; of these, 88% considered daratumumab (D), lenalidomide (R), dexamethasone(d) (DRd) or D-containing quadruplet (quad) regimens as most efficacious for use as 1L therapy for TIE NDMM. Neuropathy was cited as the greatest challenge in treating TIE NDMM with bortezomib (V; 94%), with 89% of panelists stating that it has prevented them from prescribing V. Regarding optimal DoT, panelists agreed that the treatment should be continued until progression as long as benefits outweigh risk (89%). **Conclusions:** A panel of MM experts reached clinical consensus that it was important to utilize the most effective regimen as 1L therapy for TIE NDMM. Most panelists agreed that DRd or D-containing quad regimens were the most effective 1L treatment for TIE NDMM. In the absence of absence of H2H trials among current triplet and quad regimens, these findings may help physicians with decision making.

Introduction: Long-term proteasome inhibitor (PI) therapy can improve outcomes for patients (pts) with MM, but is challenging in routine practice. This is due to PI-related toxicity and administration burden, particularly for elderly/frail pts who are often transplant ineligible. For such pts, it is important to prolong progression-free survival (PFS) and to improve depth/duration of response. The prospective, community-based, phase 4 US MM-6 study investigated *in*-class transition (*i*CT) from parenteral V-based induction to all-oral ixazomib-lenalidomide-dexamethasone (IRd) in pts with newly diagnosed MM (NDMM; NCT03173092). **Methods:** Following 3 cycles of V-based induction, eligible pts with NDMM were enrolled to receive up to 39 cycles of IRd. The primary endpoint was 2-year PFS. Secondary endpoints included treatment duration, overall response rate (ORR), overall survival (OS), and

to MM-specific predictors demonstrated superior predictive performance (AUC 0.87, Brier score 0.15). Being prescribed a diuretic, a beta-blocker, an opioid, or having chronic kidney disease were among the top predictors contributing to mortality risk. **Conclusions:** Our findings in a real-world population of older adults with MM initiating treatment highlight that including information on multimorbidity alongside MM-specific information yields far superior prediction of mortality compared to a focus only on MM-specific information. Further investigation into the disease-disease, disease-drug, and drug-drug interactions that mediate this risk will yield important clinical insights into the mechanisms of mortality in patients treated outside of clinical trials.

Introduction: Long-term proteasome inhibitor (PI) therapy can improve outcomes for patients (pts) with MM, but is challenging in routine practice. This is due to PI-related toxicity and administration burden, particularly for elderly/frail pts who are often transplant ineligible. For such pts, it is important to prolong progression-free survival (PFS) and to improve depth/duration of response. The prospective, community-based, phase 4 US MM-6 study investigated *in*-class transition (*i*CT) from parenteral V-based induction to all-oral ixazomib-lenalidomide-dexamethasone (IRd) in pts with newly diagnosed MM (NDMM; NCT03173092). **Methods:** Following 3 cycles of V-based induction, eligible pts with NDMM were enrolled to receive up to 39 cycles of IRd. The primary endpoint was 2-year PFS. Secondary endpoints included treatment duration, overall response rate (ORR), overall survival (OS), and

safety. Endpoints were assessed by age (<75 vs ≥75 years [yrs]) and frailty status (non-frail vs frail). **Results:** At datacut (Oct 17, 2022), 140 pts had received IRd; 42% were aged ≥75 yrs (median age: 73 yrs) and 61% were frail. Overall median follow-up was 27 months (mos). For pts aged <75 vs ≥75 yrs and for non-frail vs frail pts, 12 vs 7% and 13 vs 8% were ongoing on IRd, respectively. Median duration of IRd was 11 mos overall, 14 vs 9 mos in pts aged <75 vs ≥75 yrs, and 12 vs 10 mos in non-frail vs frail pts. Overall median duration of all PI-based therapy was 14 mos, 18 vs 12 mos in pts aged <75 vs ≥75 yrs, and 15 vs 13 mos in non-frail vs frail pts. ORR increased from 62% at the end of induction (including complete response [CR]: 8%) to 80% (including CR: 37%) following *i*CT to IRd; for pts aged <75 vs ≥75 yrs, ORR increased from 60 to 80% vs 64 to 80%; and in non-frail vs frail subgroups, ORR increased from 70 to 81% vs 57 to 79%. The overall 2-year PFS rate was 71% (95% confidence interval [CI]: 61–78), 72% (95% CI: 60–81) vs 67% (95% CI: 50–80) in pts aged <75 vs ≥75 yrs, and 74% (95% CI: 58–85) vs 68% (95% CI: 55–78) in non-frail vs frail pts; differences were not significant. Median PFS and OS were not reached overall, nor in any subgroup. Overall, 98% of pts experienced ≥1 treatment-emergent adverse event (TEAE; 69% grade ≥3; 44% serious TEAEs). For pts aged <75 vs ≥75 yrs, 69 vs 68% experienced a grade ≥3 TEAE; serious TEAEs occurred in 42 vs 47%; TEAEs leading to dose modification occurred in 67 vs 66%; and 2 pts died in each subgroup. For non-frail vs frail subgroups, 61 vs 73% experienced a grade ≥3 TEAE; serious TEAEs occurred in 39 vs 48%; TEAEs leading to dose modification occurred in 61 vs 70%; and 1 vs 3 pts died, respectively. **Conclusions:** *i*CT from V-based induction to all-oral IRd permits prolonged PI-based therapy and improves depth of response, with a tolerable safety profile, including in elderly/frail pts. For such pts, IRd may be an alternative to induction/maintenance.

Introduction: Daratumumab, lenalidomide and dexamethasone (DRd) and bortezomib, lenalidomide and dexamethasone (VRd) are the only guideline recommended preferred regimens for the treatment of transplant ineligible (TIE) patients with newly diagnosed multiple myeloma (NDMM). Both DRd and VRd have demonstrated superior efficacy vs. Rd in the MAIA and SWOG S0777 trials, respectively, but there is no head-to-head (H2H) clinical trial comparing their efficacy. Differing populations in MAIA (TIE [99% patients aged ≥65 years]) and S0777 (transplant not-intended [43% patients aged ≥65 years]) trials, make a naïve unadjusted comparison of outcomes across these trials challenging and biased. The current TAURUS chart review study is the first H2H study comparing the progression-free survival (PFS) among TIE NDMM patients treated with DRd or VRd as first-line of therapy (1L) in similar clinical settings. **Methods:** A multicenter chart review study was conducted at 9 academic and community cancer centers across the US. Patients ≥65 years with NDMM, considered TIE by the treating physician were included if they initiated DRd/VRd as 1L between January 2019 and September 2021. The sample included all eligible patients treated with DRd and a random sample of VRd patients. PFS was defined as the time from DRd/VRd initiation until disease progression (per physician assessment and guided by the IMWG criteria) or death. Comparability of baseline characteristics between cohorts was assessed using standardized differences (std.diff.). Characteristics with std.diff. ≥10% were considered imbalanced. The Inverse Probability of Treatment Weighting (IPTW) method was used to balance characteristics. A doubly robust Cox regression model, adjusting for clinically relevant baseline characteristics which remained imbalanced after weighting, was used to compare PFS between cohorts. **Results:** Charts of 99 DRd and 78 VRd patients were abstracted. After weighting (DRd weighted n=91, VRd weighted n=87), mean age of patients (DRd: 76.2 years, VRd: 75.9 years) and gender distribution (female; DRd: 51%, VRd: 52%) were similar between cohorts. ECOG categories, 1q21 gain/amplification, and other high-risk cytogenetics (t-[4;14], t-[14;16], del [17p]) were also well balanced. Small differences were observed in year of index date and ISS staging, which were added as regressors to the Cox model. At data cut-off, 13 DRd (14.5%) and 24 VRd (28.2%) patients experienced disease progression or death. Patients treated with 1L DRd had a 65% lower risk of disease progression or death compared to 1L VRd (adjusted hazard ratio=0.35, 95% CI: 0.17-0.73, p< 0.01). **Conclusions:** DRd is associated with a significantly lower risk of disease progression or death compared to VRd as 1L treatment for TIE NDMM patients. Results from the current TAURUS chart review study could help inform the selection of optimal 1L treatment for these patients in the absence of H2H trial comparing these two guideline recommended regimens.

safety. Endpoints were assessed by age (<75 vs ≥75 years [yrs]) and frailty status (non-frail vs frail). **Results:** At datacut (Oct 17, 2022), 140 pts had received IRd; 42% were aged ≥75 yrs (median age: 73 yrs) and 61% were frail. Overall median follow-up was 27 months (mos). For pts aged <75 vs ≥75 yrs and for non-frail vs frail pts, 12 vs 7% and 13 vs 8% were ongoing on IRd, respectively. Median duration of IRd was 11 mos overall, 14 vs 9 mos in pts aged <75 vs ≥75 yrs, and 12 vs 10 mos in non-frail vs frail pts. Overall median duration of all PI-based therapy was 14 mos, 18 vs 12 mos in pts aged <75 vs ≥75 yrs, and 15 vs 13 mos in non-frail vs frail pts. ORR increased from 62% at the end of induction (including complete response [CR]: 8%) to 80% (including CR: 37%) following *i*CT to IRd; for pts aged <75 vs ≥75 yrs, ORR increased from 60 to 80% vs 64 to 80%; and in non-frail vs frail subgroups, ORR increased from 70 to 81% vs 57 to 79%. The overall 2-year PFS rate was 71% (95% confidence interval [CI]: 61–78), 72% (95% CI: 60–81) vs 67% (95% CI: 50–80) in pts aged <75 vs ≥75 yrs, and 74% (95% CI: 58–85) vs 68% (95% CI: 55–78) in non-frail vs frail pts; differences were not significant. ECOG categories, 1q21 gain/amplification, and other high-risk cytogenetics (t-[4;14], t-[14;16], del [17p]) were also well balanced. Small differences were observed in year of index date and ISS staging, which were added as regressors to the Cox model. At data cut-off, 13 DRd (14.5%) and 24 VRd (28.2%) patients experienced disease progression or death. Patients treated with 1L DRd had a 65% lower risk of disease progression or death compared to 1L VRd (adjusted hazard ratio=0.35, 95% CI: 0.17-0.73, p< 0.01). **Conclusions:** DRd is associated with a significantly lower risk of disease progression or death compared to VRd as 1L treatment for TIE NDMM patients. Results from the current TAURUS chart review study could help inform the selection of optimal 1L treatment for these patients in the absence of H2H trial comparing these two guideline recommended regimens.

Introduction: The International Myeloma working Group introduced a frailty index (IMWG-FI), which classifies patients as either fit, intermediate-fit or frail, based on age, comorbidities and dependency in (instrumental) activities of daily living ((I)ADL). A simplified frailty index (S-FI) has been introduced, replacing (I)ADL by the WHO performance score (WHO-PS). Even though both scores predict outcome, it is currently unknown whether the level of frailty is identical between the 2 scores. **Methods:** This is a pooled analysis of the HOVON 123 and HOVON 143 studies. In the HOVON 123 study, 238 non-transplant eligible newly diagnosed multiple myeloma patients, were treated with 9 cycles of melphalan, prednisone and bortezomib. In the HOVON 143 study, 65 frail and 65 intermediate fit NTE-NDMM patients, according to the IMWG-FI, were treated with 9 cycles of ixazomib, daratumumab and low dose dexamethasone (Ixa-Dara-dex), followed by maintenance until progression with a maximum of 2 years. Patients with unknown frailty score, either according to the IMWG-FI or S-FI, were excluded from analysis. Patients were classified as fit, intermediate fit and frail, using both indexes to determine the concordance rates and to investigate patient characteristics and clinical outcome of the different frailty groups. **Results:** The IMWG-FI and S-FI were missing in 19 patients. As fit patients were underrepresented (n=8) we excluded this subgroup, leaving 341 patients. Of the 67 patients who were intermediate-fit according to the S-FI, 61 patients (91%) remained intermediate-fit and 6 (9%) patients were reclassified to frail when using the IMWG-FI. Of the 272 patients who were frail based on the S-FI, 202 patients (74%) remained frail, however, 70 patients (26%) were reclassified to intermediate-fit when using the IMWG-FI. These 70 frail patients who would be classified as intermediate-fit when using the IMWG-FI had favorable patient- and disease characteristics, compared to the 202 patients who were frail according to both scores. They were younger (>80 years: 0% versus 56%), more often ADL independent (100% vs 69%) and IADL independent (93% vs 40%), had less comorbidities (CCI ≤1: 80% vs 49%) and a more favorable ISS stage (ISS 3: 27% vs 48%). In addition, PFS2 and OS were significantly longer in these 70 reclassified patients (median PFS2 40.0 versus 29.1m, HR 0.66 (95% CI: 0.47-0.91), p=0.01 and median OS 50.6m versus 24.1m, HR 0.55 (95% CI: 0.39-0.80), p=0.0014), as compared to the 202 patients who were frail based on both scores. **Conclusions:** We here show that the S-FI identifies more patients as frail, including patients that would have been classified as intermediate fit when the gold standard, the IMWG-FI, was used. These reclassified frail patients have favorable patient- and disease characteristics, translating in a superior PFS2 and OS as compared to the subgroup of frail patients who were defined frail in both classifications. This hampers comparisons between studies using the S-FI versus the IMWG-FI.

Introduction: Second revision of ISS (R2-ISS) enhanced the prognostic value of R-ISS; however, its impact on transplant ineligible (TI) Multiple Myeloma (MM) patients was not clearly defined. We aimed to evaluate prognostication of R2-ISS in TI population in the real-world in comparison with other well-known prognostic factors for OS i.e., age, performance status, renal function, and ultra-high-risk MM (UHR). **Methods:** We analyzed 780 newly diagnosed TI MM patients with complete data for R2-ISS diagnosed between 2003-2022 (median age 74 years, range 65-91; M/F: 384/396; IgG: 475, IgA: 209, light chain: 75, IgD: 7, non-secretory: 11, IgM: 3). **Results:** Forty-seven percent were ≥75 years, 52% had ECOG ≥2, 27% had CKD-EPI eGFR < 40mL/min/1.73m^2, 46% had anemia (Hb < 10g/dL), and 29%/12% had ISS-3/R-ISS-3, respectively. Per R2-ISS, 128 patients were classified in low (I), 254 in low-intermediate (II), 355 in intermediate-high (III) and 43 in high risk (IV) group; UHR MM [including two of the following: del17p, t(4;14), t(14;16) and +1q21] was found in 68/780 (8.7%) patients. Regarding therapy, 215 patients received upfront either lenalidomide-based triplets (LBT; n=135) or daratumumab-based regimens (DBR; n=80) (28%). The rest received mostly bortezomib combinations or Rd (389; 50%); ORR was 83% (CR: 18%). After a median follow up of 72 months (mo) (95% CI: 65-79), 478 patients died (61%); median PFS and OS was 24 mo (95% CI: 22-26) and 50 mo (95% CI: 44-56), respectively; 2nd line therapy was given in 369/780 patients; median post-progression OS was 17 mo (95% CI: 13-20). In the univariate cox regression analysis age ≥75 vs. 65-74, R-ISS, R2-ISS, UHR MM, ECOG ≥2, CKD-EPI < 40 vs. ≥40 mL/min/1.73m, anemia and treatment with LBT/DBR were significant predictors for OS. Age ≥75, CKD-EPI < 40 mL/min/1.73m^2, ECOG ≥2 and UHR MM maintained their negative prognostication in the multivariate analysis [HzRs: age ≥75: 1.4, CKD-EPI < 40 mL/min/1.73m^2: 1.57, ECOG ≥2: 1.76 and UHR MM: 1.6; p< 0.05); prognostic significance of R2-ISS was marginal (p=0.05). Median OS for R2-ISS I-IV was, 72.6 mo (95% CI: 59-86), 66 mo (95%CI: 53-82), 43 mo (95% CI: 37-49) and 15 mo, respectively (p< 0.001). Age ≥75, CKD-EPI < 40, mL/min/1.73m^2, ECOG ≥2 and UHR MM, scoring 1 point each, composed a model that recognized 4 prognostic risk groups: low: 0 points, low-intermediate: 1 point, intermediate-high 2 points and high ≥3 points. Median OS for patients classified as low risk (n=185), low-intermediate (n=298), intermediate-high (n=203) and high (n=94) was 79 mo (95% CI: 65-92), 60 mo (95% CI: 52-68), 42 mo (95% CI: 36-48) and 15 mo (95% CI:9-20), respectively (HzR: low vs. high: 0.21, low-intermediate vs. high: 0.32 and intermediate-high vs. high: 0.46; p< 0.001). **Conclusions:** In conclusion, age ≥75 years, CKD-EPI < 40mL/min/1.73m^2, ECOG≥2 and UHR MM were the strongest negative predictors for OS, building up a 4-group prognostic score for TI MM patients. Prognostic impact of R2-ISS was marginal. Further validation is warranted.

Machine learning assisted risk stratification of newly diagnosed multiple myeloma with respect to the VRd treatment

Jamin Koo[1], Gyucheol Choi[2], Sung-Soo Park[3], Ja Min Byun[4], Sungwon Lim[1], Jong Cheol Lee[5]

[1]ImpriMed, Inc.; [2]ImpriMedKorea, Inc.; [3]Department of Hematology, Seoul St. Mary's Hematology Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [4]Department of Internal Medicine, Seoul National University College of Medicine, Seoul National University Hospital, Seoul, Korea; [5]Ulsan University

Introduction: Bortezomib plus lenalidomide plus dexamethasone (VRd) regimen has been administered as the first-line treatment for newly diagnosed multiple myeloma (NDMM). While the regimen generally offers a high response rate and improved survival, as much as 15% of the patients suffered from early death and/or disease progression in our retrospective analysis. We thus developed the machine learning (ML) models predicting survival of the NDMM patients following the VRd treatment so as to assist personalized treatment selection. **Methods:** We used the Multiple Myeloma Research Foundation's dataset (IA17) and identified 254 transplant ineligible NDMM treated by the VRd regimen as the first-line therapy. ML models were developed using the XGBoost (eXtreme Gradient Boosting) method. From the total of 148 demographic and clinical variables, a minimal set was chosen via sequential forward feature selection. The overall survival (OS) model was trained to compute the time-course of changes in the probability of being alive using accelerated failure time. The MMRF cohort was divided into the training and validation set during 5-fold cross-validation via the StratifiedKFold that minimizes the differences in the composition of classes such as international staging system (ISS) across the folds. The predictive performance of the trained ML models was assessed with respect to the ROC–AUC recorded during validation. We used the computed probability of survival (t = 36 months) during validation for the VRd-specific risk stratification. **Results:** Clinical characteristics of the VRd treatment group within the MMRF dataset were as follows. The median age was 68 years, with 63% of the patients being male. IgG isotype was the most dominant (38%), and the majority belonged to the ISS stage I (38%) and II (40%). The median progression-free survival (PFS) and OS of the group were 49 and 94 months, respectively. The ML models achieved the ROC-AUC of up to 0.886 when predicting OS by the three years (36 months) following the first administration of VRd regimen. The median OS of the high and low risk groups were significantly different (29 months vs not reached, P < 0.0001), recording the hazard ratio of 7.14 (95% CI, 4.48-11.38). The following covariates were identified as being the most important when predicting the risk of early death following the VRd treatment: UAMS 70 gene index, CD56 expression, serum lambda level, white blood cell counts, FISH results with respect to 8p22 and CYLD. **Conclusions:** In conclusion, we used the ML method to stratify the transplant ineligible NDMM into the high and low risk subgroups with respect to administration of the VRd regimen as the first-line treatment. Together with the previously developed ML models predicting response and survival following the VMP or Rd treatment, the proposed ML model can

The role of lenalidomide-dexamethasone therapy in elderly patients with multiple myeloma in clinical practice: comparison with bortezomib-based therapy

Jihyun Kwon[1], Yong-Pyo Lee[2], Hee Sue Park[1]

[1]Chungbuk National University College of Medicine; [2]Chungbuk National University Hospital

Introduction: No clinical trials have directly compared the continuous use of lenalidomide plus dexamethasone (Rd) with a fixed-duration treatment using proteasome inhibitors. In this study, we aimed to identify the role of Rd and proteasome inhibitor-based therapies as frontline treatments for elderly patients with multiple myeloma (MM). **Methods:** We collected and retrospectively analyzed the clinical data of 78 patients with MM who were ineligible for autologous hematopoietic stem cell transplantation (Auto-HSCT). Patients who received Rd as the first treatment were defined as group R and those who received bortezomib-based treatment were defined as group V. The primary endpoints of this study were overall survival and progression-free survival after first-line treatment. **Results:** The median age was 77.1 years (range 64.4–88.7). High-risk cytogenetics were confirmed in 11 patients. Thirty-nine patients (50.0%) received bortezomib-based therapy as the first treatment and 32 (41.0%) received Rd therapy. Patients in group R were older than those in group V (median age 79.3 vs 75.2 years, P=0.003). Three patients in group V had del(17p13) with none in group R. There was no significant difference between the two groups in the distribution of risk groups according to the International Staging System (ISS) and the Revised-ISS. The overall response rate was 74.2% in group R and 74.4% in group V (P=0.987). The time to best response was significantly shorter in group V than in group R. (6.8 vs 9.2 months, P=0.043). The median progression-free survival was 28.8 months in group R and 20.2 months in group V (P=0.042). The most common reason for treatment discontinuation in group R was treatment-related complications (15 patients, 55.6%). In group V, 15 patients (38.5%) terminated treatment according to the plan, followed by complications (12 patients, 30.8%). Twenty-five (64.1%) patients in group V received second-line lenalidomide-based therapy, whereas only seven (21.9%) patients in group R received secondary treatment. The period from the completion of the first treatment to the start of the second treatment was 1.0 months in group R and 3.7 months in group V (P=0.042). The median progression-free survival of the second-line treatment was significantly longer in group V (22.6 months) than in group R (5.4 months) (P=0.001). The median overall survival was 26.6 months in group R and 48.7 months in group V (P=0.010). In the multivariate analysis, significant prognostic factors were age >76 years (hazard ratio 3.398, P< 0.001) and ISS III risk group (hazard ratio 8.367, P=0.043). **Conclusions:** The type of primary treatment did not affect overall survival. Rd therapy showed superior progression-free survival compared with bortezomib-based regimens, despite the relatively older age of the patients. However, it is necessary to consider the high early termination rate due to complications and disadvantages caused by short drug holiday periods.

Impact of exclusion from clinical trials in non-candidate transplant patients with newly diagnosed multiple myeloma

Luis Gerardo Rodríguez-Lobato[1], Anna de Daniel i Bisbe[1], Natalia Tovar[1], Carlos Fernández de Larrea[1], Maria Teresa Cibeira[1], Raquel Jiménez-Segura[1], David Moreno[1], Aina Oliver-Caldés[1], Joan Bladé[1], Laura Rosinol[1]

[1]Hospital Clínic de Barcelona, IDIBAPS

Introduction: Medical societies recommend the inclusion of newly diagnosed multiple myeloma (NDMM) patients in clinical trials (CTs), but the actual number of patients who cannot be included and the associated prognosis remains unknown. Furthermore, there are concerns about the generalization of CT results to real-world clinical practice due to strict patient recruitment criteria. Our objective was to analyze the main causes of exclusion of non-transplant-eligible NDMM patients from CTs and to evaluate the outcomes of patients treated within or outside of CTs. **Methods:** We included 211 NDMM patients between 2003 and 2017. The above-mentioned interval was divided into three time periods (period 1: 03-07, period 2: 08-12, and period 3: 13-17). 106 (50%) received treatment outside of CTs (OCT), while 105 patients (50%) were included in a CT (89% in a phase III CT); among the included patients, 43 (40%) were randomized to the control group (CG), and 62 (60%) were assigned to the experimental group (EG). CT inclusion was analyzed as a time-dependent covariate. **Results:** Patients included in CTs were younger, had better renal function, and had a better ECOG performance status. The main causes for non-inclusion in CTs were comorbidities (41%), ECOG>2 (30%), renal insufficiency (14%), very advanced age (12.3%), and patient refusal (10%). The number of days between diagnosis and treatment initiation was longer for patients included in CTs (CT=27.5 vs. OCT=17; P=0.002). The complete response rate was similar in the first two analyzed periods regardless of the type of treatment received, while in the last period, the EG group showed an improvement (period 3: EG=28% vs. CG=18% vs. OCT=3%; P< 0.001). The median follow-up for the entire population was 46 months. The median progression-free survival (PFS) was similar in the first two periods (03-12; P=NS), showing only a benefit in the EG in the last period (EG=32 vs. CG=17.5 vs. OCT=15 months; P< 0.001). The median overall survival (OS) was longer in patients included in CTs (EG and CG) compared to the OCT group in the two last studied periods (period 2: EG=75 vs. CG=57 vs. OCT=26 months; period 3: EG=not reached vs. CG=71 vs. OCT=36; P< 0.001). **Conclusions:** Half of the non-transplant candidate NDMM patients cannot be included in CTs because they do not meet the inclusion criteria, primarily due to the presence of comorbidities. Patients included in CTs, even those randomized to the control group, have a longer OS than non-included patients. This OS benefit is due to a selection

assist personalized treatment selection for the transplant ineligible NDMM.

The role of lenalidomide-dexamethasone therapy in elderly patients with multiple myeloma in clinical practice: comparison with bortezomib-based therapy

Jihyun Kwon[1], Yong-Pyo Lee[2], Hee Sue Park[1]

[1]Chungbuk National University College of Medicine; [2]Chungbuk National University Hospital

Introduction: No clinical trials have directly compared the continuous use of lenalidomide plus dexamethasone (Rd) with a fixed-duration treatment using proteasome inhibitors. In this study, we aimed to identify the role of Rd and proteasome inhibitor-based therapies as frontline treatments for elderly patients with multiple myeloma (MM). **Methods:** We collected and retrospectively analyzed the clinical data of 78 patients with MM who were ineligible for autologous hematopoietic stem cell transplantation (Auto-HSCT). Patients who received Rd as the first treatment were defined as group R and those who received bortezomib-based treatment were defined as group V. The primary endpoints of this study were overall survival and progression-free survival after first-line treatment. **Results:** The median age was 77.1 years (range 64.4–88.7). High-risk cytogenetics were confirmed in 11 patients. Thirty-nine patients (50.0%) received bortezomib-based therapy as the first treatment and 32 (41.0%) received Rd therapy. Patients in group R were older than those in group V (median age 79.3 vs 75.2 years, P=0.003). Three patients in group V had del(17p13) with none in group R. There was no significant difference between the two groups in the distribution of risk groups according to the International Staging System (ISS) and the Revised-ISS. The overall response rate was 74.2% in group R and 74.4% in group V (P=0.987). The time to best response was significantly shorter in group V than in group R. (6.8 vs 9.2 months, P=0.043). The median progression-free survival was 28.8 months in group R and 20.2 months in group V (P=0.042). The most common reason for treatment discontinuation in group R was treatment-related complications (15 patients, 55.6%). Real world outcomes of undocumented multiple myeloma patients: a safety net hospital experience

Aishwarya Sannareddy[1], Sharlene Dong[1], Ramya Sankarasubramanian[1], Umar Khan[1], Heather Reves[1], Shifa Kanjwal[1], Navid Sadeghi[1], Radhika Kainthla[1], Heather Wolfe[2], Elif Yilmaz[2], Farrukh Awan[2], Praveen Ramakrishnan Geethakumari[2], Yazan Madanat[2], Adeel Khan[2], Aimaz Afrough[2], Robert Collins[2], Larry Anderson[2], Jenny Li[1], Gurbakhash Kaur[2]

[1]UT Southwestern Medical Center; [2]Cellular Therapy and Hematologic Malignancies Program, Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX, USA

Introduction: There are approximately 16-29 million undocumented immigrants (UI) in United States (US). UIs face more 2-fold problems in seeking medical care compared to the general population due to various financial and social burdens which include fear of deportation, language barriers, and low socioeconomic status. Most UIs are not eligible for Medicaid, state-based or employer-sponsored coverage plans, and rely on safety net hospital systems. UIs diagnosed with hematological malignancies, such as multiple myeloma (MM), face additional burdens of financially prohibitive therapies and the need for frequent provider and infusion visits. Studies have shown that immigration status can lead to disparate health outcomes, but these outcomes are poorly defined. In this study, we aim to highlight the real-world outcomes of a unique population of UIs diagnosed with MM. **Methods:** We performed a retrospective analysis on 450 patients (pts) treated for MM at Parkland Health from 1997 to 2022. Pts were considered undocumented if a valid social security number was unavailable in their electronic health record or did not qualify for a state-based insurance plan. All pts were "transplant-ineligible" due to financial constraints and lack of insurance coverage. Most pts were able to access reduced cost MM therapies through Parkland's financial assistance program. We performed a survival analysis to assess the overall survival outcomes. **Results:** Of the 450 pts, 45 UIs were identified. 99% of UIs were Hispanic and 78% were < 55 years at diagnosis. 35 pts (77%) were enrolled in financial assistance programs and 10 pts had no insurance on file. The average distance travelled to access treatment was 12.68 miles. 25 (55%) had cytogenetic abnormalities such as gain in chromosome 1q, 17 p deletion, and t (4;14) found in 7 (16%), 4 (9%) and 5 (11%). 27 (60%) had ≥50% plasma cell burden. 18 received 1st line therapy, 13 received 2nd line, 5 received 3rd line, 3 received 4th line, and 3 received 5th line therapy. Most commonly used 1st line therapies were VRD (28%), VD (15.5%), Dara-RD (13%), and Dara-VRD (8%). 2nd line therapies were Dara-RD (8.8%), IRD (8.8%) and KRD (6.6%); and 3rd line therapies were Dara-RD (4.4%) and KPD (2.2%). 1 pt underwent a stem cell transplant. 23 pts expired or were lost to follow-up (51%). The median overall survival (OS) was 4.92 years and 1 year OS (95% CI), 96% (74.8% to 98.9%), 5 year OS 48% (23.4% to 72.6%) and 10 year OS - 0%. **Conclusions:** Our study highlights key demographic characteristics in a unique cohort of UIs and reflects the challenges they face in accessing cancer care in the US. These pts frequently present with advanced and symptomatic disease at diagnosis and often require multiple lines of subsequent therapy; however, due to early death and frequent loss to follow up, less than half are alive and in follow up at 5 years, suggesting inferior outcomes compared to documented patients. Further research is warranted regarding the healthcare needs and experiences of UIs.

Ocular adverse events and functional impact in transplant ineligible, newly diagnosed multiple myeloma patients treated with belantamab mafodotin, lenalidomide and dexamethasone in BelaRd trial

Evangelos Terpos[1], Ioannis Ntanasis-Stathopoulos[1], Maria Gavriatopoulou[1], Panagiotis Malandrakis[1], Despina Fotiou[1], Magdalini Migkou[1], Foteini Theodorakakou[1], Vassiliki Spiliopoulou[1], Rodanthi Syrigou[1], Evangelos Eleutherakis-Papaiakovou[1], Stavros Gkolfinopoulos[2], Kyriaki Manousou[2], Efstathios Kastritis[1], Meletios Dimopoulos[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece; [2]Health Data Specialists, Dublin, Ireland

Introduction: Ocular adverse events (OAEs), manifesting as visual acuity changes, ocular symptoms, and corneal findings, are common with belantamab mafodotin (belamaf; GSK2857916) and the main reason for dose modifications. Here, we present the OAEs and the associated functional impairment in transplant-ineligible (TI), newly diagnosed multiple myeloma (NDMM) patients (pts) treated with an extended dose schedule of belamaf in the phase 1/2 BelaRd study. **Methods:** BelaRd (NCT04808037) is an open-label, phase 1/2 study conducted in Greece, aiming to enroll 66 TI NDMM pts. In Part 1, which investigates the safety/clinical activity of belamaf plus Rd, 36 pts are randomized (1:1:1) to receive belamaf at doses of 2.5, 1.9 or 1.4 mg/kg. In this part, belamaf is initially administered q8w and, depending on toxicity, dosing may be rescheduled to q12w. Ocular exams include Snellen best corrected visual acuity (BCVA) and slit lamp corneal evaluation. Ocular symptoms are classified by CTCAE v5.0, while the Ocular Surface Disease Index (OSDI) captures dry eye disease and activities of daily living (ADL). This descriptive analysis included all Part 1 pts (cut-off date 15/04/23). **Results:** Among 201/227/192 BCVA assessments in cohorts 2.5/1.9/1.4, a worse than 20/50 result (in the better seeing eye) was observed in 21 (10%)/23 (10%)/18 (9%), while BCVA ≤ 20/200 was noted in 2 (1%)/3 (1%)/11 (6%), with a median time to resolution of 1 month. Across all cohorts, the most frequently reported ocular symptom ≥Gr 2 was dry eye (174/618, 28%), while ≥Gr3 keratopathy was noted in <

bias, which hinders the extrapolation of CT results to real clinical practice and should be considered when selecting treatment for patients who usually do not meet the inclusion criteria.

Ocular exams include Snellen best corrected visual acuity (BCVA) and slit lamp corneal evaluation. Ocular symptoms are classified by CTCAE v5.0, while the Ocular Surface Disease Index (OSDI) captures dry eye disease and activities of daily living (ADL). This descriptive analysis included all Part 1 pts (cut-off date 15/04/23). **Results:** Among 201/227/192 BCVA assessments in cohorts 2.5/1.9/1.4, a worse than 20/50 result (in the better seeing eye) was observed in 21 (10%)/23 (10%)/18 (9%), while BCVA ≤ 20/200 was noted in 2 (1%)/3 (1%)/11 (6%), with a median time to resolution of 1 month. Across all cohorts, the most frequently reported ocular symptom ≥Gr 2 was dry eye (174/618, 28%), while ≥Gr3 keratopathy was noted in <

bias, which hinders the extrapolation of CT results to real clinical practice and should be considered when selecting treatment for patients who usually do not meet the inclusion criteria.

Real world outcomes of undocumented multiple myeloma patients: a safety net hospital experience

Aishwarya Sannareddy[1], Sharlene Dong[1], Ramya Sankarasubramanian[1], Umar Khan[1], Heather Reves[1], Shifa Kanjwal[1], Navid Sadeghi[1], Radhika Kainthla[1], Heather Wolfe[2], Elif Yilmaz[2], Farrukh Awan[2], Praveen Ramakrishnan Geethakumari[2], Yazan Madanat[2], Adeel Khan[2], Aimaz Afrough[2], Robert Collins[2], Larry Anderson[2], Jenny Li[1], Gurbakhash Kaur[2]

[1]UT Southwestern Medical Center; [2]Cellular Therapy and Hematologic Malignancies Program, Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX, USA

Introduction: There are approximately 16-29 million undocumented immigrants (UI) in United States (US). UIs face more 2-fold problems in seeking medical care compared to the general population due to various financial and social burdens which include fear of deportation, language barriers, and low socioeconomic status. Most UIs are not eligible for Medicaid, state-based or employer-sponsored coverage plans, and rely on safety net hospital systems. UIs diagnosed with hematological malignancies, such as multiple myeloma (MM), face additional burdens of financially prohibitive therapies and the need for frequent provider and infusion visits. Studies have shown that immigration status can lead to disparate health outcomes, but these outcomes are poorly defined. In this study, we aim to highlight the real-world outcomes of a unique population of UIs diagnosed with MM. **Methods:** We performed a retrospective analysis on 450 patients (pts) treated for MM at Parkland Health from 1997 to 2022. Pts were considered undocumented if a valid social security number was unavailable in their electronic health record or did not qualify for a state-based insurance plan. All pts were "transplant-ineligible" due to financial constraints and lack of insurance coverage. Most pts were able to access reduced cost MM therapies through Parkland's financial assistance program. We performed a survival analysis to assess the overall survival outcomes. **Results:** Of the 450 pts, 45 UIs were identified. 99% of UIs were Hispanic and 78% were < 55 years at diagnosis. 35 pts (77%) were enrolled in financial assistance programs and 10 pts had no insurance on file. The average distance travelled to access treatment was 12.68 miles. 25 (55%) had cytogenetic abnormalities such as gain in chromosome 1q, 17 p deletion, and t (4;14) found in 7 (16%), 4 (9%) and 5 (11%). 27 (60%) had ≥50% plasma cell burden. 18 received 1st line therapy, 13 received 2nd line, 5 received 3rd line, 3 received 4th line, and 3 received 5th line therapy. Most commonly used 1st line therapies were VRD (28%), VD (15.5%), Dara-RD (13%), and Dara-VRD (8%). 2nd line therapies were Dara-RD (8.8%), IRD (8.8%) and KRD (6.6%); and 3rd line therapies were Dara-RD (4.4%) and KPD (2.2%). 1 pt underwent a stem cell transplant. 23 pts expired or were lost to follow-up (51%). The median overall survival (OS) was 4.92 years and 1 year OS (95% CI), 96% (74.8% to 98.9%), 5 year OS 48% (23.4% to 72.6%) and 10 year OS - 0%. **Conclusions:** Our study highlights key demographic characteristics in a unique cohort of UIs and reflects the challenges they face in accessing cancer care in the US. These pts frequently present with advanced and symptomatic disease at diagnosis and often require multiple lines of subsequent therapy; however, due to early death and frequent loss to follow up, less than half are alive and in follow up at 5 years, suggesting inferior outcomes compared to documented patients. Further research is warranted regarding the healthcare needs and experiences of UIs.

Ocular adverse events and functional impact in transplant ineligible, newly diagnosed multiple myeloma patients treated with belantamab mafodotin, lenalidomide and dexamethasone in BelaRd trial

Evangelos Terpos[1], Ioannis Ntanasis-Stathopoulos[1], Maria Gavriatopoulou[1], Panagiotis Malandrakis[1], Despina Fotiou[1], Magdalini Migkou[1], Foteini Theodorakakou[1], Vassiliki Spiliopoulou[1], Rodanthi Syrigou[1], Evangelos Eleutherakis-Papaiakovou[1], Stavros Gkolfinopoulos[2], Kyriaki Manousou[2], Efstathios Kastritis[1], Meletios Dimopoulos[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece; [2]Health Data Specialists, Dublin, Ireland

Introduction: Ocular adverse events (OAEs), manifesting as visual acuity changes, ocular symptoms, and corneal findings, are common with belantamab mafodotin (belamaf; GSK2857916) and the main reason for dose modifications. Here, we present the OAEs and the associated functional impairment in transplant-ineligible (TI), newly diagnosed multiple myeloma (NDMM) patients (pts) treated with an extended dose schedule of belamaf in the phase 1/2 BelaRd study. **Methods:** BelaRd (NCT04808037) is an open-label, phase 1/2 study conducted in Greece, aiming to enroll 66 TI NDMM pts. In Part 1, which investigates the safety/clinical activity of belamaf plus Rd, 36 pts are randomized (1:1:1) to receive belamaf at doses of 2.5, 1.9 or 1.4 mg/kg. In this part, belamaf is initially administered q8w and, depending on toxicity, dosing may be rescheduled to q12w. Ocular exams include Snellen best corrected visual acuity (BCVA) and slit lamp corneal evaluation. Ocular symptoms are classified by CTCAE v5.0, while the Ocular Surface Disease Index (OSDI) captures dry eye disease and activities of daily living (ADL). This descriptive analysis included all Part 1 pts (cut-off date 15/04/23). **Results:** Among 201/227/192 BCVA assessments in cohorts 2.5/1.9/1.4, a worse than 20/50 result (in the better seeing eye) was observed in 21 (10%)/23 (10%)/18 (9%), while BCVA ≤ 20/200 was noted in 2 (1%)/3 (1%)/11 (6%), with a median time to resolution of 1 month. Across all cohorts, the most frequently reported ocular symptom ≥Gr 2 was dry eye (174/618, 28%), while ≥Gr3 keratopathy was noted in <

2% of assessments. Regarding OSDI, from 186/217/181 responses received, the number of "all/most' of the time worst responses in the ocular symptoms category were 5 (3%)/6 (3%)/8 (4%), while the respective proportions in the ADL category were 6 (3%)/4 (2%)/3 (2%). In terms of missed doses, among 122/129/112 planned belamaf infusions across cohorts, the number of skipped doses due to OAEs were 48 (39%)/41 (32%)/30 (27%). The overall response rate was 100%, no disease progression was observed over a median follow-up of 18.7 months, and 29 (81%) patients achieved at least VGPR while 15 (42%) achieved at least CR, with a median time to first response of 1 month. **Conclusions:** Belamaf-Rd, with the extended schedule for belamaf, had a minimal impact in vision-related functioning, as the 'all/most' of the time worst answers in the ADL category of OSDI was < 3% across cohorts. Furthermore, the frequency of clinically relevant impairment in vision was low, as a meaningful BCVA decline was observed in ≤10% of assessments, with a rapid time to resolution. Finally, the treatment combination induced rapid, deep and durable responses across all dose levels. In conclusion, this novel extended belamaf schedule nearly eradicates the risk for clinically relevant ocular toxicity and impact on ADL, without any compromise in clinical activity.

Safety and clinical activity of belantamab mafodotin plus lenalidomide and dexamethasone in transplant ineligible patients with newly diagnosed multiple myeloma: the phase 1/2 BelaRd study

Evangelos Terpos[1], Maria Gavriatopoulou[1], Ioannis Ntanasis-Stathopoulos[1], Panagiotis Malandrakis[1], Despina Fotiou[1], Magdalini Migkou[1], Foteini Theodorakakou[1], Vassiliki Spiliopoulou[1], Rodanthi Syrigou[1], Evangelos Eleutherakis-Papaiakovou[1], Stavros Gkolfinopoulos[2], Kyriaki Manousou[2], Efstathios Kastritis[1], Meletios Dimopoulos[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece; [2]Health Data Specialists, Dublin, Ireland

Introduction: The combination of lenalidomide and dexamethasone (Rd) is preferred in the treatment of transplant ineligible (TI) patients (pts) with newly diagnosed multiple myeloma (NDMM). Belantamab mafodotin (belamaf; GSK2857916) is an antibody-drug conjugate targeting BCMA, which has shown efficacy in pretreated MM pts. Preclinical data demonstrate synergy between belamaf and lenalidomide, while these drugs do not have overlapping toxicities. Thus, there is a strong rationale for investigating the belamaf-Rd combination in TI NDMM pts. **Methods:** BelaRd (NCT04808037) is an open-label, phase 1/2 study conducted in Greece, aiming to enroll 66 TI NDMM pts. Here we report results from Part 1 which evaluates the safety/tolerability of three belamaf doses (2.5/1.9/1.4 mg/kg) plus Rd in 36 pts and establishes the recommended phase 2 dose (cut-off date 15/04/2023). In this part, belamaf is initially administered q8w and, depending on toxicity, dosing may be rescheduled to q12w. **Results:** Of the 36 pts [median age: 72.5 years; male: 19 (53%)] in Part 1, 29 (81%) are still on treatment, while 7 (19%) have discontinued [6 pts due to belamaf-unrelated fatal events: (COVID-19 infection: 1/1/2; Pneumonia: 1/1/0, for cohorts 2.5/1.9/1.4 respectively); 1 pt withdrew consent]. The median belamaf administrations and number of cycles reached were 6/7/7 and 18.5/21.5/18.5, for the respective cohorts. The most common (≥10% of pts) non-ocular ≥ Gr3 treatment-emergent adverse events were fatigue (21 pts, 58%; [7 (58%)/7 (58%)/7 (58%)]), rash (6 pts, 17%; [2 (17%)/2 (17%)/2 (17%)]), diarrhoea (8 pts, 22%; 2 (17%)/3 (25%)/3 (25%)]), insomnia (4 pts, 11%; 0/4 (33%)/0]) and COVID-19 infection (5 pts, 14%; [2 (17%)/1 (8%)/2 (17%)]), while no ≥Gr3 thrombocytopenias and infusion-related reactions were reported. Regarding ≥Gr3 infections other than COVID, pneumonia was reported for 3 (8%) pts [1 (8%)/1 (8%)/1 (8%)]. Among 201/227/192 best corrected visual acuity (BCVA) assessments in cohorts 2.5/1.9/1.4, a worse than 20/50 result (in the better seeing eye) was observed in 21 (10%)/23 (10%)/18 (9%), while BCVA ≤20/200 was noted in 2 (1%)/3 (1%)/11 (6%). The overall response rate was 100% across all cohorts. More specifically, CR or better was achieved in 6 (50%)/4 (33%)/5 (42%), VGPR in 3 (25%)/7 (58%)/4 (33%) and PR in 3 (25%)/1 (8%)/3 (25%) of the pts in cohorts 2.5/1.9/1.4, with a median time to first response of 1 month. Finally, over a median follow-up of 18.7 months no disease progression was observed. **Conclusions:** Belamaf-Rd, with the extended schedule for belamaf, has shown a very manageable safety profile with minimal impact in vision-related functioning in an elderly, non-fit pt population. Meanwhile, a very promising clinical activity is observed with rapid, deep and durable responses across all dose levels. Consequently, after validation with bigger pt numbers, this novel combination may well be a very attractive frontline option for this vulnerable TI-NDMM population.

Therapeutic efficacy of ixazomib-based regimen in frail patients with newly diagnosed multiple myeloma based on the dynamic assessment of frailty

Hua Xue[1], Mei Jian Xu[1]

[1]Affiliated Hospital of Hebei University

Introduction: The treatment of multiple myeloma in the elderly is challenging with a high heterogeneity, and most of clinical trial findings about MM are not suitable to elderly frail patients (10-20%). More real-world studies are urgently needed to seek for effective, highly tolerable regimens to elderly frail patients with MM based on the dynamic assessment of frailty, thus guiding clinical management. To explore the efficacy and safety of the oral proteasome inhibitor ixazomib-based regimen in frail patients with newly diagnosed MM based on the dynamic assessment of frailty in the real world. **Methods:** A total of 17 elderly patients (NDMM) who were managed by a minimal of 2 cycles of oral proteasome inhibitor ixazomib-based regimen and assessed as Frail by the geriatric assessment scoring system of IMWG-GA in Affiliated Hospital of Hebei University from January 1, 2018 to June 30, 2022 were recruited. The objective ORR, PFS, OS, and AEs were recorded. **Results:** A total of 17

2% of assessments. Regarding OSDI, from 186/217/181 responses received, the number of "all/most' of the time worst responses in the ocular symptoms category were 5 (3%)/6 (3%)/8 (4%), while the respective proportions in the ADL category were 6 (3%)/4 (2%)/3 (2%). In terms of missed doses, among 122/129/112 planned belamaf infusions across cohorts, the number of skipped doses due to OAEs were 48 (39%)/41 (32%)/30 (27%). Therapeutic efficacy of ixazomib-based regimen in frail patients with newly diagnosed multiple myeloma based on the dynamic assessment of frailty

Hua Xue[1], Mei Jian Xu[1]

[1]Affiliated Hospital of Hebei University

Introduction: The treatment of multiple myeloma in the elderly is challenging with a high heterogeneity, and most of clinical trial findings about MM are not suitable to elderly frail patients (10-20%). More real-world studies are urgently needed to seek for effective, highly tolerable regimens to elderly frail patients with MM based on the dynamic assessment of frailty, thus guiding clinical management. To explore the efficacy and safety of the oral proteasome inhibitor ixazomib-based regimen in frail patients with newly diagnosed MM based on the dynamic assessment of frailty in the real world. **Methods:** A total of 17 elderly patients (NDMM) who were managed by a minimal of 2 cycles of oral proteasome inhibitor ixazomib-based regimen and assessed as Frail by the geriatric assessment scoring system of IMWG-GA in Affiliated Hospital of Hebei University from January 1, 2018 to June 30, 2022 were recruited. The objective ORR, PFS, OS, and AEs were recorded. **Results:** A total of 17

eligible elderly patients with NDMM were recruited, and their baseline characteristics were listed in Table 1. Among them, there were 11 (64.7%) patients aged 75 years and older, and 15 (88.2%) patients with a minimal of Eastern Cooperative Oncology Group (ECOG) score of 2 points. All recruited patients were initially given ixazomib and dexamethasone (ID regimen). After 2-3 cycles of ID regimen, the frailty and therapeutic efficacy were dynamically assessed. After the improvement of frailty, those who had a worse efficacy than partial response (PR) or high risk assessed by the Revised Multiple Myeloma International Staging System (R-ISS) were additionally given cyclophosphamide (n=5), or lenalidomide (n=1) or daratumumab(n=1). The detailed treatment regimens were shown in Table 2. The median number of cycles of treatment for all patients was 7 (3-11), and the median ORR was 82.3% (14/17), and 16/17 (94.1%) achieving minimal response (MR) and above. Two deaths were reported, both of whom were older than 80 years and combined with multiple comorbidities. One patient died of treatment discontinuation at 17 months, and the other died of gastrointestinal bleeding at 2 years. Early deaths were not reported. Four patients experienced disease progression after self-withdrawal, and 11 patients were still managed by ixazomib-based regimen. The median follow-up period was 9.0 (2.6-37.0) months. The median PFS and median OS were not reached. All 17 patients were assessed for safety, and the overall tolerance was acceptable. Most of AEs were grade 1-2. None of them withdrew due to AEs. **Conclusions:** For frail patients with MM, an initial treatment of ID regimen is effective and safe based on the dynamic assessment of IMWG-GA, suggesting that the oral ID regimen is a first-line treatment to elderly frail patients with NDMM. Clinical benefits and the optimal regimen for elderly frail patients with MM adjusted based on the stratification of the frailty still needs evidence-based medical data.

Ixazomib versus lenalidomide or ixazomib and lenalidomide combination as maintenance regimen for transplant-ineligible multiple myeloma: update of a multi-center prospective study in China

Introduction: Maintenance therapy (MT) deepens response and prolongs progression free survival (PFS) in patients with newly diagnosed multiple myeloma (NDMM) after frontline regimens. Ixazomib, a 2nd generation oral proteasome inhibitor (PI), has been approved for MT due to convenience and tolerability. We conducted this prospective multi-center study to compare the efficacy and safety of Ixazomib (I-MT) or Ixazomib plus Lenalidomide (IL-MT) to Lenalidomide (L-MT) as maintenance regimen in transplant-ineligible NDMM patients. **Methods:** This study was approved by the Institutional Review Board of Peking Union Medical College Hospital and registered (NCT04217967). NDMM patients were enrolled from 10 centers of North China MM Registry, since September 2019. Patients receiving up to 5-9 cycles of front-line regimens and reaching at least partial response (PR) started MT. If PR was not reached after 4 cycles, 2nd-line induction for 2-5 cycles would be conducted till PR was reached. Ixazomib 4mg was given on day 1,8,15. Lenalidomide 25mg was given every other day on days 1–21 in a 28-day cycle. Patients in dual-drug group were administrated with both Ixazomib and Lenalidomide, dose as listed above. The primary endpoint was progression free survival (PFS) from MT. **Results:** A total of 200 patients were enrolled, including 74 in I-MT, 76 in L-MT and 50 in IL-MT. Patients in L-MT group was younger than those in I-MT and IL-MT group (median age of 61.0±8.1ys, vs 65.2±8.5ys and 63.5±8.3ys, respectively, p=0.03). The proportion of deletion 17p was slightly higher in IL-MT group. While other baseline characteristics, including gender ratio, paraprotein isotype, international staging system (ISS), revised-ISS (R-ISS), were comparable among different MT regimen groups. The median follow-up duration since maintenance was 27, 28 and 23 months in I-MT, L-MT and IL-MT, respectively. There were 75.6%, 80.3% and 80% of the patients reached very good remission (VGPR) or better before MT, while the rates of deep responses improved to 85.1%, 87.1% and 88% during follow-up. Progressive disease (PD) was recorded in 46.7% (N=32) of patients on I-MT, 31.6% (N=24) on L-MT and 36% (N=18) on IL-MT, respectively. The median PFS was 29.3m, not reached (NR) and 22.9m, while OS was not reached in all groups. Cox model multivariate analysis suggested that I-MT and IL-MT provided similar PFS to that of L-MT (HR 95% CI 0.57-1.95, p=0.87; and HR 95% CI 0.56-1.96, p=0.87; respectively). The main reason of MT withdrawal was disease progression. Adverse event related discontinuation was 8.3%, 0% and 20%, respectively. **Conclusions:** We design this multi-centered prospective study to evaluate whether dual drug maintenance will further strengthen response in non-transplant NDMM patients. Our preliminary data suggest that more clinicians in the real practice are inclined to prescribe IL-MT for high-risk patients. Whether dual-drug maintenance will provide better survival still needs to be defined.

Adding value of serum-free light chain in assessing response and progression in multiple myeloma with measurable disease

Elham Askari[1], Vincent Rajkumar[1], David Murray[1], Angela Dispenzieri[1], Prashant Kapoor[1], Moritz Binder[1], Francis Baudi[1], Joselle Cook[1], David Dingli[1], Amie Fonder[1], Morie Gertz[1], Wilson Gonsalves[1],

eligible elderly patients with NDMM were recruited, and their baseline characteristics were listed in Table 1. Among them, there were 11 (64.7%) patients aged 75 years and older, and 15 (88.2%) patients with a minimal of Eastern Cooperative Oncology Group (ECOG) score of 2 points. All recruited patients were initially given ixazomib and dexamethasone (ID regimen). After 2-3 cycles of ID regimen, the frailty and therapeutic efficacy were dynamically assessed. After the improvement of frailty, those who had a worse efficacy than partial response (PR) or high risk assessed by the Revised Multiple Myeloma International Staging System (R-ISS) were additionally given cyclophosphamide (n=5), or lenalidomide (n=1) or daratumumab(n=1). The detailed treatment regimens were shown in Table 2. The median number of cycles of treatment for all patients was 7 (3-11), and the median ORR was 82.3% (14/17), and 16/17 (94.1%) achieving minimal response (MR) and above. Two deaths were reported, both of whom were older than 80 years and combined with multiple comorbidities. One patient died of treatment discontinuation at 17 months, and the other died of gastrointestinal bleeding at 2 years. Early deaths were not reported. Four patients experienced disease progression after self-withdrawal, and 11 patients were still managed by ixazomib-based regimen. The median follow-up period was 9.0 (2.6-37.0) months. The median PFS and median OS were not reached. All 17 patients were assessed for safety, and the overall tolerance was acceptable. Most of AEs were grade 1-2. None of them withdrew due to AEs. **Conclusions:** For frail patients with MM, an initial treatment of ID regimen is effective and safe based on the dynamic assessment of IMWG-GA, suggesting that the oral ID regimen is a first-line treatment to elderly frail patients with NDMM. Clinical benefits and the optimal regimen for elderly frail patients with MM adjusted based on the stratification of the frailty still needs evidence-based medical data.

[1]Mayo Clinic, Rochester, MN, USA

Introduction: Highly effective therapies in multiple myeloma (MM), highlights the need for more sensitive biomarkers for response and progression assessments. Serum-free light chain (s-FLC) has a high specificity /sensitivity for detecting monoclonal paraprotein. The difference between Involved and uninvolved FLC (d-FLC) is used by the International Myeloma Working Group (IMWG) for assessing the response/progression in non secretory MM. We attempt to validate if the serial measurement of s-FLC, adds value in monitoring MM with measurable disease. **Methods:** This retrospective study included newly diagnosed (MM), evaluated at mayo clinic (Rochester) between 2011-2021. All patients had s-FLC measurable (Involved FLC level ≥ 10 mg/dL, with abnormal ratio) at baseline plus measurable serum and/or urine with serial matched data available. All 3 biomarkers were measured at baseline, after each cycle, and at the time of best response and disease progression. We performed a direct comparison of response categories between 3 markers at each time point. **Results:** A total of 841 patients were included, 52% IgMM, 20% light chain (MM) and 28% with measurable M-protein in both serum and urine. After the first cycle of treatment, the major response rates (VGPR, PR) by FLC were (42%,40%), sPEP (11%,47%), and uPEP (51%,17%) (Figure 1). MRRs> 90%, observed earlier by s-FLC (2nd cycle) than by s/u M-protein (4th cycle). Among 81% of patients who achieved ≥VGPR at best response, 90% had response by FLC and urine.In patients with paraprotein response < VGPR, achieving FLC response ≥ VGPR, was associated with better PFS (HR 0.65, P < 0.03). Median d-FLC was reduced by 86% after cycle 1, compared to urine M-protein of 91% (Figure 2). The correlation coefficients between the percentage change of d-FLC and urine M-protein after each cycle, showed a moderate relationship, (r 0.562-0.607,p < .001). A higher degree of correlation was detected in LCCM (r 0.607-0.771,P < .001). After a median follow-up of 51 months, 56% had progression disease (PD): 62% by s-FLC, 56% by serum M-protein and 24% by urine. (Figure 3). Among the 48% of patients with measurable urine M-protein at baseline, 58% developed PD, however only 19.5% had progression by urine M-protein and 68%, presented PD by s-FLC. All patients with PD by urine, had PD by s-FLC. Among 13% (60) of total patients with PD, s-FLC was the only tumor marker detectable. **Conclusions:** In this study, a similar response rate between serum FLC and urine paraprotein confirms the current cutoffs used for response categories for s-FLC. Serum FLC changes closely paralleled the changes in measurable urine protein and suggest that 24-hour urine can be replaced by serum FLC for response and progression. With direct comparison, we detected the effect of treatment response earlier with FLC in multiple time points.We also detected in 13% of patients with progression, the serum FLC as the only marker of progression, suggesting value of FLC in monitoring for relapse/progression.

Bone marrow plasmacytosis >5% at time of autologous transplant influences survival outcomes in patients with standard risk cytogenetics

Hussein Awada[1], Adel Hajj Ali[2], Bardia Khosravi[3], Jason Valent[4], Shahzad Raza[4], Sandra Mazzoni[4], Christy Samaras[4], Craig Sauter[4], Rahul Banerjee[5], Claudio Brunstein[4], Ronaldo Sobecks[4], Matt Kalaycio[4], Jack Khouri[4], Faiz Anwer[4], Louis Williams[1]

Introduction: Autologous hematopoietic cell transplant (AHCT) remains the standard consolidation in multiple myeloma (MM) patients who achieve at least partial response to induction chemotherapy. Indeed, AHCT aims to deepen response in MM patients while also prolonging remission in a disease of known eventual relapse. Here, we explored our internal cohort of MM patients undergoing AHCT to test whether a BMPC cut off of 5% provides survival advantages in patient who responded to a single line of modern induction therapy. **Methods:** We screened all MM patients who underwent AHCT between 2011 and 2021. Inclusion criteria included transplant within 12 months of diagnosis, receiving a single line of modern induction chemotherapy, and absence of relapse prior to AHCT. Patients were subsequently stratified into BMPC < 5% and ≥5% pre-AHCT. Kaplan-Meier analysis determined median overall survival (mOS) and median progression free survival (mPFS) post-AHCT with subgroup analysis according to the cytogenetic risk categories as well. **Results:** A total of 311 patients with available data were included in our study. On further BMPC stratification, we identified 233 (74.9%) patients with BMPC < 5% and 78 (25.1%) patients with BMPC ≥5% at AHCT, respectively. Both groups had similar baseline characteristics, including age at diagnosis (median 61.5 vs 60.4 years; P=0.86), age at transplant (62.0 vs 61.0 years; P=0.87), smoking history (65.9 vs 64.8%, 30.2 vs 33.8%, 3.9 vs 1.4% for never, prior, and current smokers; P=0.54), sex (Males 59.2 vs 61.1%; P=0.78), ethnicity (White 84.5 vs 91.7%; P=0.31); Eastern Cooperative Oncology Group (ECOG) performance status (P=0.81), International Scoring System stages (33.7 vs 38.7%, 42.7 vs 32.3%, 23.6 vs 29%, for stage I, II, and III; P=0.34), cytogenetic risk (High-risk 41.4 vs 37.7%; P=0.61), Immunoglobulin subtype (IgG 69.2 vs 66.1%; P=0.65), Melphalan dose (high dose 200 mg/m^2 97.0 vs 98.6%; P=0.45), and Mobilization regimen (G-CSF + Plerixafor 87.1 vs 88.7%; P=0.71) for BMPC < 5% and BMPC ≥5% at AHCT, respectively. Patients with < 5% BMPC had better probability of OS (median 88.8 vs 68.1 months; HR 0.6 95% CI 0.3-1.2; P=0.07), but it did not reach statistical significance. There was no difference in PFS (median 35.5 vs 33.1 months; HR 0.8 95% CI 0.5-1.2; P=0.2), for the BMPC < 5% and BMPC ≥5% groups. On subgroups analysis, no differences were noted in OS (median 70.1 vs 68.1 months; HR 0.4 95% CI 0.1-1.3; P=0.13) and PFS (median 22.6 vs 22.4 months; HR 0.9 95% CI 0.5-1.7; P=0.72) for

Here, we explored our internal cohort of MM patients undergoing AHCT to test whether a BMPC cut off of 5% provides survival advantages in patient who responded to a single line of modern induction therapy. **Methods:** We screened all MM patients who underwent AHCT between 2011 and 2021. Inclusion criteria included transplant within 12 months of diagnosis, receiving a single line of modern induction chemotherapy, and absence of relapse prior to AHCT. Patients were subsequently stratified into BMPC < 5% and ≥5% pre-AHCT. Kaplan-Meier analysis determined median overall survival (mOS) and median progression free survival (mPFS) post-AHCT with subgroup analysis according to the cytogenetic risk categories as well. **Results:** A total of 311 patients with available data were included in our study. On further BMPC stratification, we identified 233 (74.9%) patients with BMPC < 5% and 78 (25.1%) patients with BMPC ≥5% at AHCT, respectively. Both groups had similar baseline characteristics, including age at diagnosis (median 61.5 vs 60.4 years; P=0.86), age at transplant (62.0 vs 61.0 years; P=0.87), smoking history (65.9 vs 64.8%, 30.2 vs 33.8%, 3.9 vs 1.4% for never, prior, and current smokers; P=0.54), sex (Males 59.2 vs 61.1%; P=0.78), ethnicity (White 84.5 vs 91.7%; P=0.31); Eastern Cooperative Oncology Group (ECOG) performance status (P=0.81), International Scoring System stages (33.7 vs 38.7%, 42.7 vs 32.3%, 23.6 vs 29%, for stage I, II, and III; P=0.34), cytogenetic risk (High-risk 41.4 vs 37.7%; P=0.61), Immunoglobulin subtype (IgG 69.2 vs 66.1%; P=0.65), Melphalan dose (high dose 200 mg/m^2 97.0 vs 98.6%; P=0.45), and Mobilization regimen (G-CSF + Plerixafor 87.1 vs 88.7%; P=0.71) for BMPC < 5% and BMPC ≥5% at AHCT, respectively. Patients with < 5% BMPC had better probability of OS (median 88.8 vs 68.1 months; HR 0.6 95% CI 0.3-1.2; P=0.07), but it did not reach statistical significance. There was no difference in PFS (median 35.5 vs 33.1 months; HR 0.8 95% CI 0.5-1.2; P=0.2), for the BMPC < 5% and BMPC ≥5% groups. On subgroups analysis, no differences were noted in OS (median 70.1 vs 68.1 months; HR 0.4 95% CI 0.1-1.3; P=0.13) and PFS (median 22.6 vs 22.4 months; HR 0.9 95% CI 0.5-1.7; P=0.72) for

patients who are of high risk cytogenetics. In contrast, patients who are of standard risk cytogenetics had statistically significant lower OS (median 86.6 vs 95.4 months; HR 0.3 95% 0.1-0.9; P=0.04) but not in mPFS (median 77.4 vs 34.4 months; OR 0.5 95% CI 0.2-1.1; P=0.06) if they belonged to the BMPC ≥5% group. **Conclusions:** A BMPC cut off of 5% at AHCT may be a useful prognostic marker for survival outcomes in MM patients of standard risk cytogenetics being evaluated for AHCT.

Daratumumab – VTD vs VTD: peri-transplant evaluation

Virginia Jano[1], Belen Ballina[1], Julia Vidan[1], Abdolah Ahmadi[1], Maryam Arefi[1], María del Carmen Gilabert[1], Agata Almela[1], Irene Padilla[1], Jose Antonio Rodríguez[1], Fernando Escalante[1]

[1]University Hospital of Leon

Introduction: Multiple myeloma (MM) is the primary indication for autologous peripheral blood stem cell transplantation (PBSCT) worldwide. The combination of Daratumumab, Velcade, Thalidomide, Dexamethasone (DVTD) has been approved for induction treatment in newly diagnosed MM (MMND) patients eligible for PBSCT. Daratumumab is a human monoclonal antibody IgG1k that binds to the CD38 protein expressed at high levels on the surface of plasma cells, inhibiting their growth through various mechanisms of action. **Objective:** To evaluate if DVTD increases the risk of hematologic toxicity, the need for blood transfusions, and complications derived from this myelotoxicity (bleeding, mucositis, febrile neutropenia). **Materials and methods:** This is a series of 38 patients treated at our hospital from 2013 to March 2022. Twenty-nine patients received VTd and 9 patients received the DVTd regimen. Conditioning regimen with MEL200 [MEL140 in patients with renal insufficiency]. **Results:** Clinical and biological characteristics were similar, with a mean age of 57.22 in the Daratumumab arm compared to 62.21 in the arm without Daratumumab, and a very similar distribution by gender: Females 44.8% (Daratumumab arm) and 55.5% (arm without Daratumumab), and Males 55.2% (Daratumumab arm) and 44.5% (arm without Daratumumab). Hematologic toxicity: We did not find differences in the recovery of cytopenias, clinical toxicity, transfusion requirements, or number of days until medical discharge. Peripheral blood stem cell collection is adequate, with no significant differences in the number of apheresis sessions, but there are statistically significant differences in the use of plerixafor. **Conclusions:** We observed a greater difficulty in collecting hematopoietic progenitor cells in patients receiving treatment with Daratumumab, requiring a higher administration of plerixafor. However, we did not find statistically significant differences in terms of toxicity. Therefore, we can conclude that DVTd treatment is effective and well-tolerated.

[1]Hematology Unit, San Bortolo hospital, Vicenza, Italy; [2]Immunology and Molecular Oncology Diagnostics, Veneto Institute of Oncology IOV - IRCCS, Padua, Italy; [3]Department of Medicine (DIMED), Hematology and Clinical Immunology section, Padua University School of Medicine, Padua, Italy; [4]Hematology Unit, Ospedale dell'Angelo, Mestre-Venezia, Italy; [5]Department of Medicine, Section of Hematology, University of Verona, Verona, Italy; [6]Clinica Ematologica e Unità di Terapie Cellulari, Azienda Sanitaria Universitaria Friuli Centrale (ASUFC), Dipartimento di Area Medica (DAME), Università di Udine, Udine, Italia; [7]U.O.C Ematologia, Ospedale Santa Maria di Ca' Foncello, Treviso, Italia.; [8]Onco Hematology, Department of Oncology, Veneto Institute of Oncology IOV - IRCCS, Padua, Italy

Introduction: The pathogenesis of Multiple Myeloma (MM) is settled by primary or secondary genetic abnormalities. According to Revised International Staging System (R-ISS) t(4;14), t(14;16) and del17p are considered high risk (HR) aberrations, while all other abnormalities are considered standard risk (SR). However, recent evidence suggests that t(14;16) translocation could not be associated with dismal outcome in the novel agents era. The aim of this study was to evaluate the prognostic impact of t(14;16) translocation in the real-life setting and to compare the outcome of this subgroup with a cohort of SR patients. **Methods:** The study cohort included 47 active MM patients with t(14;16) translocation diagnosed from 2004 to 2022. Patients' characteristics including clinical and biological features at diagnosis, type of treatment and OS were collected. These cases were compared with 227 SR patients according to R-ISS. **Results:** Median age of the cohort was 65 years. Baseline clinical features included ISS III and R-ISS III in 19/40 (47.5%) cases and high LDH levels in 16/38 (42%) cases. Considering additional cytogenetic abnormalities, del17p has been detected in 16/47 (34%) of patients while +1q abnormalities in 36/47 (76.6%) cases (gain1q in 20 cases and amp1q in 16 cases). Considering the treatment received, almost all patients were treated with a proteasome inhibitor (45/47, 95.7%) and most received an IMID (35/47, 74.5%), while 22/47 (46.8%) patients received an anti-CD38 monoclonal antibody and 21/47 (41.68%) at least one autologous stem cell transplantation. Median OS of the entire cohort of was 75 months. T(14;16) patients harboring del17p showed reduced survival as compared to patients without del17p (32 months vs not reached, p=0.0395), while +1q abnormalities (either amp1q or gain1q) did not significantly affect the outcome (p=0.8204). We then compared the outcome of the

patients who are of high risk cytogenetics. In contrast, patients who are of standard risk cytogenetics had statistically significant lower OS (median 86.6 vs 95.4 months; HR 0.3 95% 0.1-0.9; P=0.04) but not in mPFS (median 77.4 vs 34.4 months; OR 0.5 95% CI 0.2-1.1; P=0.06) if they belonged to the BMPC ≥5% group. **Conclusions:** A BMPC cut off of 5% at AHCT may be a useful prognostic marker for survival outcomes in MM patients of standard risk cytogenetics being evaluated for AHCT.

Introduction: The pathogenesis of Multiple Myeloma (MM) is settled by primary or secondary genetic abnormalities. According to Revised International Staging System (R-ISS) t(4;14), t(14;16) and del17p are considered high risk (HR) aberrations, while all other abnormalities are considered standard risk (SR). However, recent evidence suggests that t(14;16) translocation could not be associated with dismal outcome in the novel agents era. The aim of this study was to evaluate the prognostic impact of t(14;16) translocation in the real-life setting and to compare the outcome of this subgroup with a cohort of SR patients. **Methods:** The study cohort included 47 active MM patients with t(14;16) translocation diagnosed from 2004 to 2022. Patients' characteristics including clinical and biological features at diagnosis, type of treatment and OS were collected. These cases were compared with 227 SR patients according to R-ISS. **Results:** Median age of the cohort was 65 years. Baseline clinical features included ISS III and R-ISS III in 19/40 (47.5%) cases and high LDH levels in 16/38 (42%) cases. Considering additional cytogenetic abnormalities, del17p has been detected in 16/47 (34%) of patients while +1q abnormalities in 36/47 (76.6%) cases (gain1q in 20 cases and amp1q in 16 cases). Considering the treatment received, almost all patients were treated with a proteasome inhibitor (45/47, 95.7%) and most received an IMID (35/47, 74.5%), while 22/47 (46.8%) patients received an anti-CD38 monoclonal antibody and 21/47 (41.68%) at least one autologous stem cell transplantation. Median OS of the entire cohort of was 75 months. T(14;16) patients harboring del17p showed reduced survival as compared to patients without del17p (32 months vs not reached, p=0.0395), while +1q abnormalities (either amp1q or gain1q) did not significantly affect the outcome (p=0.8204). We then compared the outcome of the

t(14;16) subgroup with a cohort of 227 SR patients, including 78 t(11;14) cases and 81 hyperdiploid (HRD) cases. Overall, t(14;16) patients showed a reduced, although non statistically significant, OS as compared to SR patients (75 vs 105 months, p=0.1104); however, after the exclusion of del17p cases, the outcome of the two subgroups was superimposable (not reached vs 105 months, p=0.9948). Of notice, t(14;16) alone cases displayed reduced OS with respect of SR cases without +1q abnormalities (38.5 vs 105 months, p=0.0231). The t(14;16) alone dismal outcome was maintained when compared with defined cytogenetic subgroups of patients, notably t(11;14) alone patients (p=0.0875) and HRD alone patients (p=0.0016). **Conclusions:** The data herein presented showed that within t(14;16) patients, the presence of del17p conferred inferior survival while +1q abnormalities did not affect the outcome. Of notice t(14;16) alone patients showed reduced survival with respect to SR patients overall and in cytogenetically defined subsets, thus confirming the negative prognostic impact of this alteration.

Retrospective assessment of outcomes with autologous bone marrow transplant in multiple myeloma - Real world data of 23 years

Tasneem Bharmal[1], Reetu Jain[1], S. H. Advani[1], Ganpati Bhatt[1], Samir Shah[1], Fahad Afzal[1], Neal Joseph[1], Asha Ojha[1], Elvis Alex[1], Payal Bhatt[1], Mamta Yargop[1], Poonam Nuingare[1], Tapan Saikia[1]

[1]Jaslok Hospital and Research Centre

Introduction: Multiple myeloma is a plasma cell dyscrasia characterised by bone marrow infiltration by clonal plasma cells. Autologous stem cell transplantation (ASCT) is a worldwide accepted standard of care for all transplant eligible newly diagnosed multiple myeloma(TE-NDMM) patients. **Methods:** This two centre retrospective study included 177 TE-NDMM patients who underwent ASCT between January 2000 to March 2023. Baseline disease characteristics and disease status prior to ASCT was recorded. All patients were staged by ISS staging. Parameters during ASCT like mucositis, ASCT stay and time to engraftment were noted. Response to ASCT, maintenance treatment, disease status at follow up and year of death were regularly updated till April 2023. As maintenance treatment was not practiced in our centres until 2015, survival outcomes for patients who received maintenance vs those who did not receive maintenance treatment was studied. **Results:** The results were analysed from January 2020 to April 2023. 67% patients are males, 33% females. Mean age is 51 years. 44 (25%) patients underwent ASCT between 2000-2010 and 133 (75%) patients underwent ASCT between 2011 till March 2023. 26%, 30% and 44.5% patients belonged to ISS stage I, II and III respectively. 83% patients had CR/VGPR prior to ASCT. 63% patients underwent Early ASCT. Drugs in induction until 2010 included Vincristine, Doxorubicin, Melphalan, Thalidomide and Dexamethasone in various combinations, from 2011 drugs used are Bortezomib, Lenalidomide, Thalidomide, cyclophosphamide and dexamethasone in various combinations. 81% patients received GCSF for stem cell mobilisation. Plerixafor for stem cell mobilisation was practiced at our centres post 2016; 19% patients received it. Melphalan dose was 200mg/m^2 in 66% patients. 89% patients had mucositis, of which 66% had grade II mucositis. 80% patients achieved neutrophil engraftment and 63% patients achieved platelet engraftment ≤14 days from the day of ASCT. Duration of stay during ASCT was ≤25 days in 72% patients. 3 patients had a treatment related mortality. 85 patients out of 177 received post transplant maintenance therapy. Lenalidomide maintenance was given to 67 (79%) patients, while Bortezomib was given to 10 patients (12%) with high risk cytogenetics. At the time of last follow up (25 Apr 2023), 117 (66%) patients were alive and 53 (30%) had died; of which 1 died due to secondary AML and rest due to disease relapse. Out of the 117 patients alive, 84 (48%) are in CR/VGPR and 79 (45%) are on further lines of therapy. Overall survival of entire cohort is 14.29 years with 95% CI (12.972, 15.616). Overall survival for patients who did not receive maintenance regimen post ASCT is 14.85 years with 95% CI (13.248, 16.467). Overall survival for patients who received a maintenance regimen post ASCT is 8.49 years with 95% CI (5.097, 8.903). **Conclusions:** Long term survival outcomes in transplant eligible NDMM are promising with low TRM and long term adverse effects.

Daratumumab (dara) as maintenance therapy after autologous stem cell transplantation (ASCT) in patients with multiple myeloma (MM): results of a phase 2 study

Azra Borogovac[1], Flavia Pichiorri[1], Jeffrey Matous[2], Jesus Berdeja[3], Alexander Pozhitkov[4], Theophilus Tandoh[4], Arnab Chowdhury[1], James Sanchez[4], Joycelynne Palmer[4], Ann Morales[4], Jonathan Keats[4,5], Scott Goldsmith[6], Myo Htut[1], Murali Janakiram[1], Nitya Nathwani[1], Michael Rosenzweig[1], Amrita Krishnan[4]

[1]City of Hope National Comprehensive Cancer Center; [2]Colorado Blood Cancer Institute, Sarah Cannon Research Institute, Denver, CO, USA; [3]Sarah Cannon Research Institute, Nashville, TN, USA; [4]City of Hope; [5]TGen; [6]City Of Hope National Medical Center, Duarte, CA, USA

Introduction: The CASSIOPEIA trial demonstrated improved PFS with maintenance dara over observation post-ASCT after bortezomib(V)-thalidomide(T)-dexamethasone(D). The role of dara as maintenance post-ASCT with other induction regimens has not been fully established. **Methods:** This open-label single-arm phase 2 study evaluated the safety and efficacy of dara maintenance after upfront high-dose ASCT. Between days 60-120 post-ASCT, pts received iv or sq dara 1800mg weekly (cycles 1-2), biweekly (cycles 3-6), and monthly for a total of 24mos. The primary objective was PFS at 1yr after start of consolidation. Secondary objectives included safety, toxicity, minimal residual disease (MRD), 2yr-PFS and OS. **Results:** Of the 31 patients (pts) enrolled between 8/2019-12/2022, 30 are evaluable. Median age was 60 yrs (range 38-70). Eight pts had ISS stage I, 10 had ISS II, 3 had ISS III, 10 pts were unknown. Among the 23 pts with available FISH, 52% had high-

t(14;16) subgroup with a cohort of 227 SR patients, including 78 t(11;14) cases and 81 hyperdiploid (HRD) cases. Overall, t(14;16) patients showed a reduced, although non statistically significant, OS as compared to SR patients (75 vs 105 months, p=0.1104); however, after the exclusion of del17p cases, the outcome of the two subgroups was superimposable (not reached vs 105 months, p=0.9948). Of notice, t(14;16) alone cases displayed reduced OS with respect of SR cases without +1q abnormalities (38.5 vs 105 months, p=0.0231). The t(14;16) alone dismal outcome was maintained when compared with defined cytogenetic subgroups of patients, notably t(11;14) alone patients (p=0.0875) and HRD alone patients (p=0.0016). **Conclusions:** The data herein presented showed that within t(14;16) patients, the presence of del17p conferred inferior survival while +1q abnormalities did not affect the outcome. Of notice t(14;16) alone patients showed reduced survival with respect to SR patients overall and in cytogenetically defined subsets, thus confirming the negative prognostic impact of this alteration.

Introduction: Multiple myeloma is a plasma cell dyscrasia characterised by bone marrow infiltration by clonal plasma cells. Autologous stem cell transplantation (ASCT) is a worldwide accepted standard of care for all transplant eligible newly diagnosed multiple myeloma(TE-NDMM) patients. **Methods:** This two centre retrospective study included 177 TE-NDMM patients who underwent ASCT between January 2000 to March 2023. Baseline disease characteristics and disease status prior to ASCT was recorded. All patients were staged by ISS staging. Parameters during ASCT like mucositis, ASCT stay and time to engraftment were noted. Response to ASCT, maintenance treatment, disease status at follow up and year of death were regularly updated till April 2023. As maintenance treatment was not practiced in our centres until 2015, survival outcomes for patients who received maintenance vs those who did not receive maintenance treatment was studied. **Results:** The results were analysed from January 2020 to April 2023. 67% patients are males, 33% females. Mean age is 51 years. 44 (25%) patients underwent ASCT between 2000-2010 and 133 (75%) patients underwent ASCT between 2011 till March 2023. 26%, 30% and 44.5% patients belonged to ISS stage I, II and III respectively. 83% patients had CR/VGPR prior to ASCT. 63% patients underwent Early ASCT. Drugs in induction until 2010 included Vincristine, Doxorubicin, Melphalan, Thalidomide and Dexamethasone in various combinations, from 2011 drugs used are Bortezomib, Lenalidomide, Thalidomide, cyclophosphamide and dexamethasone in various combinations. 81% patients received GCSF for stem cell mobilisation. Plerixafor for stem cell mobilisation was practiced at our centres post 2016; 19% patients received it. Melphalan dose was 200mg/m^2 in 66% patients. 89% patients had mucositis, of which 66% had grade II mucositis. 80% patients achieved neutrophil engraftment and 63% patients achieved platelet engraftment ≤14 days from the day of ASCT. Duration of stay during ASCT was ≤25 days in 72% patients. 3 patients had a treatment related mortality. 85 patients out of 177 received post transplant maintenance therapy. Lenalidomide maintenance was given to 67 (79%) patients, while Bortezomib was given to 10 patients (12%) with high risk cytogenetics. At the time of last follow up (25 Apr 2023), 117 (66%) patients were alive and 53 (30%) had died; of which 1 died due to secondary AML and rest due to disease relapse. Out of the 117 patients alive, 84 (48%) are in CR/VGPR and 79 (45%) are on further lines of therapy. Overall survival of entire cohort is 14.29 years with 95% CI (12.972, 15.616). Overall survival for patients who did not receive maintenance regimen post ASCT is 14.85 years with 95% CI (13.248, 16.467). Overall survival for patients who received a maintenance regimen post ASCT is 8.49 years with 95% CI (5.097, 8.903). **Conclusions:** Long term survival outcomes in transplant eligible NDMM are promising with low TRM and long term adverse effects.

Daratumumab (dara) as maintenance therapy after autologous stem cell transplantation (ASCT) in patients with multiple myeloma (MM): results of a phase 2 study

Azra Borogovac[1], Flavia Pichiorri[1], Jeffrey Matous[2], Jesus Berdeja[3], Alexander Pozhitkov[4], Theophilus Tandoh[4], Arnab Chowdhury[1], James Sanchez[4], Joycelynne Palmer[4], Ann Morales[4], Jonathan Keats[4,5], Scott Goldsmith[6], Myo Htut[1], Murali Janakiram[1], Nitya Nathwani[1], Michael Rosenzweig[1], Amrita Krishnan[4]

[1]City of Hope National Comprehensive Cancer Center; [2]Colorado Blood Cancer Institute, Sarah Cannon Research Institute, Denver, CO, USA; [3]Sarah Cannon Research Institute, Nashville, TN, USA; [4]City of Hope; [5]TGen; [6]City Of Hope National Medical Center, Duarte, CA, USA

Introduction: The CASSIOPEIA trial demonstrated improved PFS with maintenance dara over observation post-ASCT after bortezomib(V)-thalidomide(T)-dexamethasone(D). The role of dara as maintenance post-ASCT with other induction regimens has not been fully established. **Methods:** This open-label single-arm phase 2 study evaluated the safety and efficacy of dara maintenance after upfront high-dose ASCT. Between days 60-120 post-ASCT, pts received iv or sq dara 1800mg weekly (cycles 1-2), biweekly (cycles 3-6), and monthly for a total of 24mos. The primary objective was PFS at 1yr after start of consolidation. Secondary objectives included safety, toxicity, minimal residual disease (MRD), 2yr-PFS and OS. **Results:** Of the 31 patients (pts) enrolled between 8/2019-12/2022, 30 are evaluable. Median age was 60 yrs (range 38-70). Eight pts had ISS stage I, 10 had ISS II, 3 had ISS III, 10 pts were unknown. Among the 23 pts with available FISH, 52% had high-

t(14;16) subgroup with a cohort of 227 SR patients, including 78 t(11;14) cases and 81 hyperdiploid (HRD) cases. Overall, t(14;16) patients showed a reduced, although non statistically significant, OS as compared to SR patients (75 vs 105 months, p=0.1104); however, after the exclusion of del17p cases, the outcome of the two subgroups was superimposable (not reached vs 105 months, p=0.9948). Of notice, t(14;16) alone cases displayed reduced OS with respect of SR cases without +1q abnormalities (38.5 vs 105 months, p=0.0231). The t(14;16) alone dismal outcome was maintained when compared with defined cytogenetic subgroups of patients, notably t(11;14) alone patients (p=0.0875) and HRD alone patients (p=0.0016). **Conclusions:** The data herein presented showed that within t(14;16) patients, the presence of del17p conferred inferior survival while +1q abnormalities did not affect the outcome. Of notice t(14;16) alone patients showed reduced survival with respect to SR patients overall and in cytogenetically defined subsets, thus confirming the negative prognostic impact of this alteration.

Introduction: The CASSIOPEIA trial demonstrated improved PFS with maintenance dara over observation post-ASCT after bortezomib(V)-thalidomide(T)-dexamethasone(D). The role of dara as maintenance post-ASCT with other induction regimens has not been fully established. **Methods:** This open-label single-arm phase 2 study evaluated the safety and efficacy of dara maintenance after upfront high-dose ASCT. Between days 60-120 post-ASCT, pts received iv or sq dara 1800mg weekly (cycles 1-2), biweekly (cycles 3-6), and monthly for a total of 24mos. The primary objective was PFS at 1yr after start of consolidation. Secondary objectives included safety, toxicity, minimal residual disease (MRD), 2yr-PFS and OS. **Results:** Of the 31 patients (pts) enrolled between 8/2019-12/2022, 30 are evaluable. Median age was 60 yrs (range 38-70). Eight pts had ISS stage I, 10 had ISS II, 3 had ISS III, 10 pts were unknown. Among the 23 pts with available FISH, 52% had high-

risk cytogenetics. Induction regimens included lenalidomide(R)-VD in 14 pts, carfilzomib(K)-RD in 4 pts, and a combination of RVD, KRD and cyclophosphamide-VD in 5 pts. Five pts received dara prior to ASCT. Median treatment duration was 24 cycles (range 4-27) and 19 pts completed 2yrs of therapy. At a median follow-up of 22mos, 1-yr and 2-yr PFS were 85% (95% CI, 73-99%), and 74% (58-92%) respectively. One-yr PFS was 80% (59-100%) and 91% (75%-100%) in the high and standard-risk pts, respectively. During maintenance, 8 pts had a deepening of response. No grade ≥4 toxicities were observed. Four pts had grade 3 toxicity, including respiratory infection, weight gain, hypertension and back pain. Ten pts had dose delays for toxicity, predominantly infections. CyTOF data from peripheral blood of 12 pts show profound changes in the frequencies of different immune populations including terminally differentiated T cells (TEMRA), activated monocytes, and NK cells. Dara treatment rapidly induced depletion in NK cell populations, which persisted until treatment discontinuation; no association with progression was noted. Four of the 12 pts evaluated progressed within the treatment period (< 24mos) and had increased CD4 suppressive T cell populations including TIGIT, PD-1, PDL-1 and TIM3-expressing T reg cells and bulk NKT cells. Preliminary scRNA sequencing data in 4 pts showed that upon dara discontinuation, pts had an increase in CD8+ cytotoxic T cell and B regulatory cell populations carrying unique genetic features. Specifically, we found a significant deregulation in the T cell and B cell activation markers including Granulysin, Granzyme A, IFG2R, CXCR4, CXCR5, NFKBID, among others. MRD, scRNA and CyTOF analysis from the rest of the pts will be presented. **Conclusions:** Single-agent dara maintenance post-ASCT is safe and demonstrates promising PFS in high-risk and standard-risk MM. In pts progressing on dara, unique changes in the distribution of immune cell populations and increased expression of T cell immune suppressive markers were seen. **Acknowledgments:** MMRC.

Post-induction undetectable flow minimal residual disease ameliorates the high risk determined by FISH among newly diagnosed multiple myeloma

Guldane Cengiz Seval[1], Klara Dalva[1], Sule Mine Bakanay[1], Ender Soydan[1], Osman Ilhan[1], Meral Beksac[1], Gulcin Miyase Sonmez[1]

[1]Ankara University School of Medicine, Department of Hematology

Introduction: Post-induction minimal residual disease(MRD) within marrow is currently recognized as poor-prognostic among transplant-eligible patients with multiple myeloma(MM). An emerging number of studies are evaluating MRD within the context of cytogenetic risk. In this study, we aimed to quantify clonal plasma cells (PCs) by flow both in apheresis products(gMRD) and marrow(mMRD) to evaluate the impact on the outcome according to risk determined by FISH cytogenetics. **Methods:** Four hundred fifty-four subsequent newly diagnosed MM patients transplanted between 2007-2022 were included prospectively. Standard-risk cytogenetics(SR) is defined as t(11;14) or a normal karyotype, whereas del(17p13), t(4;14), t(14;16), + 1q21 and complex findings are high-risk cytogenetics(HR).Results were reported in the intention-to-treat(ITT) population for mMRD. **Results:** Median follow-up after AHCT was 32.4 mos(range:3.2-168). The induction regimen consisted of bortezomib without or with immunomodulatory drugs 77.5% and 11.9%. Consolidation 19%(n=83/437), and maintenance 27.4%(n=118/431) were administered based on the guidelines and regulations. Cytogenetically HR, standard or missing were observed in 18.5%(n=84), 77.5%(n=352) and 4%(n=18) of the total cohort. Post-induction complete response(CR) was achieved in 18.7% of patients(n=85). Following mobilization(n=453), gMRD and mMRD were undetectable in 48.9%(181/370) and 13.5%(41/303) of patients. There was a correlation between gMRD and mMRD(SE: 0.318, p< 0.001). Having undetectable mMRD estimates a 5 years-PFS of 71.3% (p< 0.001). Among 40 mMRD(-) patients, only six (two with HR) have relapsed. Likewise, 5 years-PFS according to undetectable gMRD 44.8% (p=0.02) or according to HR vs SR is 31.3% vs 37.8% (p=0.19). Distribution of patients divided into four groups according to mMRD status and cytogenetic risk are as follows: mMRD(-)SR (n=30; 10.3%), MRD(-)HR (n=9; 3.1%), MRD(+)SR (n=207; 71.4%), MRD(+)HR (n=44;15.2%). Kaplan-Meier curves revealed significant differences in median PFS among these groups; mMRD(-)SR: NR, MRD(-)HR: 50 mos, MRD(+)SR: 23.3 mos, MRD(+)HR: 18.6 mos (p=0.006). In a MVA model (age, ISS, FISH, post-induction CR or MRD) post-induction mMRD (HR:0.26 (95% CI:0.11-0.59),p< 0.001) and post-induction CR (HR:0.19 (95% CI:0.07-0.51),p< 0.001) appeared to determine PFS independently. **Conclusions:** Our real-world triplet drug induction-based and majority unmaintained experience among AHCT-eligible myeloma patients, shows post-induction mMRD to be correlated with PFS. Although observed less frequently, achieving post-induction MRD(-) marrow may ameliorate the poor prognosis of HR determined by FISH. Combined analysis of the depth of response and FISH appears to increase the significance of risk assessment. In the future, more intensive induction regimens may allow better recognition of cytogenetic and molecular sub-groups versus depth of response in the prediction of long-term outcomes.

Introduction: Factors that have an impact on myeloma prognosis among newly diagnosed multiple myeloma (NDMM) are continuously expanding leading to new staging systems. 1q gain (+1q) as an additional high-risk cytogenetic (HCR) feature has been integrated into the Mayo additive staging system (MASS). Later revised ISS has been updated with a second revision featuring 1q gain. In this retrospective analysis, we aimed to validate these

risk cytogenetics. Induction regimens included lenalidomide(R)-VD in 14 pts, carfilzomib(K)-RD in 4 pts, and a combination of RVD, KRD and cyclophosphamide-VD in 5 pts. Five pts received dara prior to ASCT. Median treatment duration was 24 cycles (range 4-27) and 19 pts completed 2yrs of therapy. Following mobilization(n=453), gMRD and mMRD were undetectable in 48.9%(181/370) and 13.5%(41/303) of patients. There was a correlation between gMRD and mMRD(SE: 0.318, p< 0.001). Having undetectable mMRD estimates a 5 years-PFS of 71.3% (p< 0.001). Among 40 mMRD(-) patients, only six (two with HR) have relapsed. Likewise, 5 years-PFS according to undetectable gMRD 44.8% (p=0.02) or according to HR vs SR is 31.3% vs 37.8% (p=0.19). Distribution of patients divided into four groups according to mMRD status and cytogenetic risk are as follows: mMRD(-)SR (n=30; 10.3%), MRD(-)HR (n=9; 3.1%), MRD(+)SR (n=207; 71.4%), MRD(+)HR (n=44;15.2%). Kaplan-Meier curves revealed significant differences in median PFS among these groups; mMRD(-)SR: NR, MRD(-)HR: 50 mos, MRD(+)SR: 23.3 mos, MRD(+)HR: 18.6 mos (p=0.006). In a MVA model (age, ISS, FISH, post-induction CR or MRD) post-induction mMRD (HR:0.26 (95% CI:0.11-0.59),p< 0.001) and post-induction CR (HR:0.19 (95% CI:0.07-0.51),p< 0.001) appeared to determine PFS independently. **Conclusions:** Our real-world triplet drug induction-based and majority unmaintained experience among AHCT-eligible myeloma patients, shows post-induction mMRD to be correlated with PFS. Although observed less frequently, achieving post-induction MRD(-) marrow may ameliorate the poor prognosis of HR determined by FISH. Combined analysis of the depth of response and FISH appears to increase the significance of risk assessment. In the future, more intensive induction regimens may allow better recognition of cytogenetic and molecular sub-groups versus depth of response in the prediction of long-term outcomes.

Validation of two international myeloma staging systems: second revision of ISS and mayo additive staging sytems (MASS) in an external cohort of Ankara University

Guldane Cengiz Seval[1], Merve Aydogan[1], Mehmet Hakan Akbulut[1], Bulent Karakaya[1], Gul Yavuz[1], Hulya Yilmaz[1], Meral Beksac[1]

[1]Ankara University School of Medicine, Department of Hematology

Introduction: Factors that have an impact on myeloma prognosis among newly diagnosed multiple myeloma (NDMM) are continuously expanding leading to new staging systems. 1q gain (+1q) as an additional high-risk cytogenetic (HCR) feature has been integrated into the Mayo additive staging system (MASS). Later revised ISS has been updated with a second revision featuring 1q gain. In this retrospective analysis, we aimed to validate these

novel scores in an independent external cohort from our Institution. **Methods:** This retrospective study is performed on a database of 524 consecutive majority transplant eligible NDMM patients treated in our center between September 2007- March 2022. As 1q amplification has been added to our FISH panels lately, 208 consecutive patients met the criteria for R2-ISS or MASS score parameters, and analysis was performed in this cohort. High-risk cytogenetics (HCR) was defined accordingly. Progression eligible for analysis-free survival (PFS) was defined as the time from the diagnosis until disease progression, relapse, or death due to any cause. **Results:** Patients (median age 61 years (33-88 years); (female/male: 47.1%/52.9%) received either bortezomib-based triplet (96.7%) without (n:142) or with an immunomodulatory drug (28.4%) as induction therapy. Out of the 208 patients, 169 patients underwent autologous hematopoietic stem cell transplantation (AHCT). As a post-ASCT treatment, consolidation (20.2%) and maintenance (38.9%) were given to patients. The median follow-up for all patients is 19.8 months (range: 3-237 mos). HCR was detected in 42 patients (20.2%) with an additional +1q identified among 96 cases, accounting for 46.2% of 208 patients. Based on the calculation of risk score in MASS; 42 patients (20.2%) ranked as score 0 (MASS I), 67 patients (32.2%) score 1 (MASS II) and 99 patients (47.6%) score +2 (MASS III). The cross-tabulation of MASS with R2-ISS will be presented late depicting a further sub-grouping of MASS scores within R2-ISS. With a median follow-up of 26.2 months, patients with +1q had significantly shorter PFS (95% CI: 18.9%-43.9%, p< 0.001) than those without +1q. The 2 years-PFS was 92.7% vs 81.1% vs 63.4% in the MASS I, II, and III groups, respectively (p< 0.001) and 95% vs 87.2% vs 73.6% vs 40.3% in the R2-ISS I, II, III, and IV groups, respectively (p< 0.001). **Conclusions:** Our single-center uniform real World data-based study confirms the prognostic role +1q as a poor prognostic parameter. The MASS-based PFS analysis shows a distinct separation of PFS curves ranging between 92.7% and 63.4%. With R2-ISS the distinctive power is expanded with PFS-2 years values ranging between 95% and 40.3%. Based on our analysis either MASS or preferably R2-ISS are both reliable and reproducible methods to powerfully predict the prognosis of patients with NDMM.

Clonal isotype switch predicts long-term survival in multiple myeloma after autologous stem cell transplantation

Hanwool Cho[1], Jinhang Kim[2], Nanyoung Yun[2], Jeong-A Kim[2]

[1]Department of Laboratory Medicine, St. Vincent Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea; [2]Division of Hematology, Department of Internal Medicine, St. Vincent Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea

Introduction: Clonal isotype switch (CIS) results in emergence of new oligoclonal immunoglobin bands that are different from the original bands identified at the time of diagnosis. CIS has been reported in patients with multiple myeloma (MM) who received a high dose melphalan chemotherapy followed by autologous stem cell transplantation (ASCT). However, clinical relevance of CIS after ASCT is still unclear. **Methods:** The retrospective analysis included 82 patients with MM who had undergone ASCT. 27 patients (38%) received a vincristine, doxorubicin and dexamethasone (VAD) as an induction treatment (IT), while 54 patients (62%) were initially treated with the bortezomib-containing IT. A CIS was observed in 26 patients (31%) of the 82 patients with a higher prevalence with the use of novel agents versus VAD in induction (40% vs. 15%; P=0.061). **Results:** In prognostic terms, revised international scoring system (R-ISS) and post-ASCT CIS status remained at a significant predictor in OS and PFS in the multivariate analysis. Interestingly, patients with CIS after ASCT had a significantly longer 10-year overall survival (OS; with CIS vs. without CIS; 56% vs. 25%, respectively; p=0.002) and 10-year progression-free survival (PFS; with CIS vs. without CIS; 52% vs. 32%, respectively; p=0.02). Among 26 patients with CIS, 11 patients had only one monoclonal band and 15 patients had developed oligoclonal bands (>2 monoclonal bands) throughout the post-ASCT follow-up period. Oligoclonal CIS was observed about 18% of patients in total 82 patients. Interestingly, the estimated 10-year OS and PFS of CIS patients with oligoclonal bands were 75.0% and 68.6%, respectively. **Conclusions:** CIS after ASCT is a favorable prognostic indicator based on its positive correlation with OS and PFS after transplantation in patients with MM. In addition, a higher frequency of CIS after ASCT was associated with the bortezomib-containing IT. The use of bortezomib-containing IT may contribute to a higher anti-tumor effect or a stronger immune reconstitution.

Introduction: The second revision of the International Staging System (R2-ISS) has recently been developed to improve the risk stratification of newly diagnosed multiple myeloma (NDMM) patients over the Revised-ISS (R-ISS). We aimed to evaluate its effectiveness in real-world clinical practice and compare its performance with the R-ISS **Methods:** We collected clinical and laboratory data from newly diagnosed MM patients treated between January 2010 and July 2019 at 13 hospitals participating in the Korean Multiple Myeloma Working Party (KMMWP) in South Korea. A total of 572 newly diagnosed MM patients who received IMiDs and/or PIs as part of their first-line treatment and had complete information on R2-ISS and R-ISS were included in the study. **Results:** The median age was 63 years (range: 36–88), with 245 patients (42.8%) being 65 years or older. According to the R2-ISS, 69 (12.0%), 163 (28.5%), 283 (49.5%), and 57 (10.0%) patients were classified as stages I, II, III, and IV, respectively. We observed a significant difference in median overall survival (OS) among the four stages of R2-ISS (111.7, 82.8, 49.1, and 26.1 months for stages I, II, III, and IV, respectively; $P < 0.001$). In addition, significant differences in OS were observed among the R2-ISS stages within the R-ISS II patients (n = 389). Median OS was not reached in R2-ISS I (n = 2), 82.8 months (95% CI: 67.3–125.9) in R2-ISS II (n = 152), 49.6 months (95% CI: 40.2–62.4) in R2-ISS III (n = 105), and 14.9 months (95% CI: 5.7–NA) in R2-ISS IV patients (n = 44) ($P < 0.001$). Notably, the R2-ISS demonstrated a significantly higher C-statistic for OS compared to the R-ISS (0.613 vs. 0.567; $P = 0.003$), along with a substantial difference in Akaike's information criterion between the two models (3709.2 vs. 3727.2). Furthermore, the R2-ISS successfully stratified patients with different survival outcomes based on age (elderly or young), treatment (PIs, IMiDs, or IMiDs plus PIs), eligibility for upfront autologous stem cell transplantation, and eligibility for clinical trial participation. **Conclusions:** In conclusion, the R2-ISS was successfully validated in real-world MM patients who received primary therapy with IMiDs and/or PIs. It showed a significant improvement in discriminatory power and model fitness compared to the R-ISS, mainly by effectively reclassifying R-ISS II patients into different risk groups. While the R2-ISS does not consider all potential risk factors, its additive nature allows for the inclusion of new prognostic variables in the future.

Phase I open-label single-arm study of dual targeting BCMA and CD19 FasTCAR-T cells (GC012F) as first-line therapy for transplant-eligible newly diagnosed high-risk multiple myeloma

Juan Du[1], Wanting Qiang[1], Jing Lu[1], Yanchun Jia[1], Haiyan He[1], Jin Liu[1], Pei Guo[1], Ying Yang[1], Zhongyuan Feng[1], Lina Jin[1], Xiaoqiang Fan[1], Jia Liu[2], Qi Zhang[2], Lianjun Shen[2], Lihong Weng[2], Wenling Li[2], Wei Cao[2]

[1]Department of Hematology, Shanghai Changzheng Hospital; [2]Gracell Biotechnologies Ltd.

Introduction: High-risk (HR) newly-diagnosed multiple myeloma (NDMM) has poor outcomes with standard first-line therapy, even in transplant-eligible (TE) patients (pts). A CAR-T therapy with high efficacy and manageable safety profile would be a potential solution to this significant unmet need. GC012F is an autologous B cell maturation antigen (BCMA) and CD19 dual-targeting CAR-T cells therapy developed on the novel FasTCAR-T enabling next-day manufacturing platform. A single arm, open-label phase I investigator-initiated study (NCT04935580) was conducted in a frontline setting for TE HR NDMM pts to assess the safety and feasibility of GC012F CAR-T cell therapy. Data was presented at ASH 2022 for initial 16 pts. Here we present updated data for study with longer follow-up and 3 additional pts treated (total n=19). **Methods:** From June 2022 to April 2023, 19 pts with median age 59 (range 43-69) were treated and evaluated with a single infusion of GC012F at 3 doses levels (DL) of 1E5/kg (n=1), 2E5/kg (n=4), or 3E5/kg (n=14), after a 3-day lymphodepletion consisting of cyclophosphamide and fludarabine. The primary objective of this study was safety; the secondary were pharmacokinetics and efficacy. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded by ASTCT 2019. Efficacy assessment was referred to the IMWG 2016 criteria. Expansion of CAR-T cells and CAR copy numbers were analyzed by flow cytometry and qPCR, respectively. **Results:** As of April 12, 2023, the median follow-up time was 14.3 months (range 1.8-21.8 months). All pts had one or more high-risk features including 89% R-ISS stage II or III and 63% with EM. All pts received 2 cycles of induction therapy prior to the infusion. The overall response rate (ORR) was100% and 100% of pts achieved stringent complete response (sCR). All pts achieved minimal residual disease (MRD) negativity assessed by Euroflow with the sensitivity of 10-6. Median duration of response (DOR) and progression-free survival (PFS) were not reached. Only 6 pts (32%) experienced low-grade cytokine release syndrome (CRS), among them 26% was grade 1 (n=5) and 5% grade 2 (n=1). No any grade CRS occurred in other 68% pts. No ICANS or deaths occurred during the study. Robust CAR T-cell expansion was observed in all pts: median Cmax was 62131 (range 8754 - 331159) copies /μg gDNA and the median Tmax was 10 days (range 9-14 days). **Conclusions:** Consistent with the previous RRMM cohort treated with GC012F, initial data from this phase I study demonstrated that BCMA-CD19 dual FasTCAR-T GC012F resulted in a deep and durable remission in TE HR NDMM pts with

Introduction: The second revision of the International Staging System (R2-ISS) has recently been developed to improve the risk stratification of newly diagnosed multiple myeloma (NDMM) patients over the Revised-ISS (R-ISS). We aimed to evaluate its effectiveness in real-world clinical practice and compare its performance with the R-ISS **Methods:** We collected clinical and laboratory data from newly diagnosed MM patients treated between January 2010 and July 2019 at 13 hospitals participating in the Korean Multiple Myeloma Working Party (KMMWP) in South Korea. A total of 572 newly diagnosed MM patients who received IMiDs and/or PIs as part of their first-line treatment and had complete information on R2-ISS and R-ISS were included in the study. **Results:** The median age was 63 years (range: 36–88), with 245 patients (42.8%) being 65 years or older. According to the R2-ISS, 69 (12.0%), 163 (28.5%), 283 (49.5%), and 57 (10.0%) patients were classified as stages I, II, III, and IV, respectively. We observed a significant difference in median overall survival (OS) among the four stages of R2-ISS (111.7, 82.8, 49.1, and 26.1 months for stages I, II, III, and IV, respectively; $P < 0.001$). In addition, significant differences in OS were observed among the R2-ISS stages within the R-ISS II patients (n = 389). Median OS was not reached in R2-ISS I (n = 2), 82.8 months (95% CI: 67.3–125.9) in R2-ISS II (n = 152), 49.6 months (95% CI: 40.2–62.4) in R2-ISS III (n = 105), and 14.9 months (95% CI: 5.7–NA) in R2-ISS IV patients (n = 44) ($P < 0.001$). Notably, the R2-ISS demonstrated a significantly higher C-statistic for OS compared to the R-ISS (0.613 vs. 0.567; $P = 0.003$), along with a substantial difference in Akaike's information criterion between the two models (3709.2 vs. 3727.2). Furthermore, the R2-ISS successfully stratified patients with different survival outcomes based on age (elderly or young), treatment (PIs, IMiDs, or IMiDs plus PIs), eligibility for upfront autologous stem cell transplantation, and eligibility for clinical trial participation. **Conclusions:** In conclusion, the R2-ISS was successfully validated in real-world MM patients who received primary therapy with IMiDs and/or PIs. It showed a significant improvement in discriminatory power and model fitness compared to the R-ISS, mainly by effectively reclassifying R-ISS II patients into different risk groups. While the R2-ISS does not consider all potential risk factors, its additive nature allows for the inclusion of new prognostic variables in the future.

Phase I open-label single-arm study of dual targeting BCMA and CD19 FasTCAR-T cells (GC012F) as first-line therapy for transplant-eligible newly diagnosed high-risk multiple myeloma

Juan Du[1], Wanting Qiang[1], Jing Lu[1], Yanchun Jia[1], Haiyan He[1], Jin Liu[1], Pei Guo[1], Ying Yang[1], Zhongyuan Feng[1], Lina Jin[1], Xiaoqiang Fan[1], Jia Liu[2], Qi Zhang[2], Lianjun Shen[2], Lihong Weng[2], Wenling Li[2], Wei Cao[2]

[1]Department of Hematology, Shanghai Changzheng Hospital; [2]Gracell Biotechnologies Ltd.

Introduction: High-risk (HR) newly-diagnosed multiple myeloma (NDMM) has poor outcomes with standard first-line therapy, even in transplant-eligible (TE) patients (pts). A CAR-T therapy with high efficacy and manageable safety profile would be a potential solution to this significant unmet need. GC012F is an autologous B cell maturation antigen (BCMA) and CD19 dual-targeting CAR-T cells therapy developed on the novel FasTCAR-T enabling next-day manufacturing platform. A single arm, open-label phase I investigator-initiated study (NCT04935580) was conducted in a frontline setting for TE HR NDMM pts to assess the safety and feasibility of GC012F CAR-T cell therapy. Data was presented at ASH 2022 for initial 16 pts. Here we present updated data for study with longer follow-up and 3 additional pts treated (total n=19). **Methods:** From June 2022 to April 2023, 19 pts with median age 59 (range 43-69) were treated and evaluated with a single infusion of GC012F at 3 doses levels (DL) of 1E5/kg (n=1), 2E5/kg (n=4), or 3E5/kg (n=14), after a 3-day lymphodepletion consisting of cyclophosphamide and fludarabine. The primary objective of this study was safety; the secondary were pharmacokinetics and efficacy. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded by ASTCT 2019. Efficacy assessment was referred to the IMWG 2016 criteria. Expansion of CAR-T cells and CAR copy numbers were analyzed by flow cytometry and qPCR, respectively. **Results:** As of April 12, 2023, the median follow-up time was 14.3 months (range 1.8-21.8 months). All pts had one or more high-risk features including 89% R-ISS stage II or III and 63% with EM. All pts received 2 cycles of induction therapy prior to the infusion. The overall response rate (ORR) was100% and 100% of pts achieved stringent complete response (sCR). All pts achieved minimal residual disease (MRD) negativity assessed by Euroflow with the sensitivity of 10-6. Median duration of response (DOR) and progression-free survival (PFS) were not reached. Only 6 pts (32%) experienced low-grade cytokine release syndrome (CRS), among them 26% was grade 1 (n=5) and 5% grade 2 (n=1). No any grade CRS occurred in other 68% pts. No ICANS or deaths occurred during the study. Robust CAR T-cell expansion was observed in all pts: median Cmax was 62131 (range 8754 - 331159) copies /μg gDNA and the median Tmax was 10 days (range 9-14 days). **Conclusions:** Consistent with the previous RRMM cohort treated with GC012F, initial data from this phase I study demonstrated that BCMA-CD19 dual FasTCAR-T GC012F resulted in a deep and durable remission in TE HR NDMM pts with

a very favorable safety profile. These preliminary results emphasize the potential of CAR-T treatment in newly-diagnosed MM pts. Additional studies with larger cohorts and longer follow-ups will further show the significance and benefits of earlier line application of CAR-T therapy for MM pts.

Introduction: Trial in progress. For patients (pts) with newly diagnosed multiple myeloma (NDMM), maintenance with the immunomodulatory drug (IMiD®) lenalidomide (LEN) is the standard of care after autologous stem cell transplantation (ASCT). All pts remain at risk for relapse post ASCT, and pts may discontinue LEN maintenance due to adverse events; therefore, there is an unmet need for new drugs with improved activity and tolerability in the maintenance setting. Iberdomide (IBER) is a novel, potent oral cereblon E3 ligase modulator (CELMoD™) with increased tumoricidal activity and enhanced immune-modulatory effects compared with IMiD® agents. The EXCALIBER-Maintenance phase 3 trial (NCT05827016) will compare the efficacy and safety of IBER maintenance with that of LEN maintenance post ASCT in pts with NDMM. **Methods:** This randomized, multicenter, controlled, open-label study will be conducted in 2 stages: in Stage 1, ≈120 pts will be randomized 1:1:1:1 to 1 of 3 IBER doses or to the LEN arm to identify the optimal IBER dose as maintenance therapy after ASCT; in Stage 2, ≈1096 additional pts will be randomized 1:1 to receive the selected IBER dose or LEN, for efficacy and safety analyses (Stage 1 pts in the selected dose cohort and LEN arm will also be included). Pts will be stratified by minimal residual disease (MRD) status (negative vs positive [10^{-4} threshold]/indeterminate), cytogenetic risk profile (high vs standard/indeterminate) at study entry, and ISS staging at initial diagnosis (I–II vs III). Key eligibility criteria include age ≥18 years; 3–6 prior cycles of induction therapy (a proteasome inhibitor + an IMiD agent ± an anti-CD38 monoclonal antibody, or bortezomib + cyclophosphamide + dexamethasone) followed by a single or tandem ASCT with or without consolidation and has not relapsed following primary therapy or is considered not responsive. Treatment in the IBER arms will consist of 28-day (D) cycles (C) with IBER given orally on D1–21 at 0.75, 1.0, or 1.3 mg in Stage 1, or at the selected dose level in Stage 2. Treatment in the LEN arms will consist of 28-D cycles with oral LEN at 10 mg on D1–28. Treatment will continue until confirmed progressive disease (PD) or unacceptable toxicity. The primary efficacy endpoint will be progression-free survival (PFS), defined as time from randomization to PD or death, and the key secondary endpoints will be MRD negativity rate and overall survival (OS). The key secondary endpoints will be tested hierarchically after the primary endpoint demonstrates superiority. Other secondary endpoints include response improvement, PFS2, time to progression, time to next treatment, safety, and health-related quality of life. Interim analyses are planned for dose selection (Stage 1) and OS (Stage 2); PFS superiority may be analyzed when sufficient OS and PFS information is available to enable such an analysis. Enrollment is expected to begin in June 2023.

Online CME improves clinical decision-making in the management of patients with multiple myeloma

Victoria Harvey-Jones[1], Sanneke Koekkoek[1], Caroline Phillips[1]

[1]WebMD/Medscape Oncology Global

Introduction: Multiple myeloma (MM) is a complex hematological malignancy for hematologists/oncologists (hem/oncs) to manage. We assessed whether an online, virtual patient simulation (VPS) activity could improve the performance of hem/oncs in ordering appropriate tests, selecting appropriate treatment, and counselling patients with MM. **Methods:** This CME-certified VPS consisted of 2 patient cases presented in a platform that allowed physicians to assess the patients and complete open-field entries, choosing from an extensive database of diagnostic and treatment options reflecting the scope and depth of actual practice. After each decision, learners received clinical guidance (CG) based on current evidence and faculty recommendations. Clinical decisions were compared pre- and post-CG using a 2-tailed paired t-test to determine P values (P<.05 is significant). Rationales for clinical decisions were collected in real time. Data were collected between March 2022 and September 2022 and reported here as % relative improvement, P value. **Results:** Case 1 (n=335 hem/oncs) 62-yr-old man with a history of hypertension referred due to fatigue, back pain with pain score 5/10, and abnormal laboratory tests. Significant changes observed for: 1. Ordering appropriate tests to evaluate the patient (SPEP/SIFE, 13%, P<.001; serum LDH, 12%, P<.01, serum FLC assay, 9%, P<.01; PET-CT, 14%, P<.01; FBC, 8%, P<.01; FISH analysis, 8%, P<.01; CrCl, 14%, P<.01; chemistry panel, 7%, P<.01; bone marrow aspirate, 7%, P<.01, beta-2 microglobulin, 7%, P<.01; diagnosis of MM, 13%, P<.001). 2. Selecting an appropriate

a very favorable safety profile. These preliminary results emphasize the potential of CAR-T treatment in newly-diagnosed MM pts. Additional studies with larger cohorts and longer follow-ups will further show the significance and benefits of earlier line application of CAR-T therapy for MM pts.

Introduction: Multiple myeloma (MM) is a complex hematological malignancy for hematologists/oncologists (hem/oncs) to manage. We assessed whether an online, virtual patient simulation (VPS) activity could improve the performance of hem/oncs in ordering appropriate tests, selecting appropriate treatment, and counselling patients with MM. **Methods:** This CME-certified VPS consisted of 2 patient cases presented in a platform that allowed physicians to assess the patients and complete open-field entries, choosing from an extensive database of diagnostic and treatment options reflecting the scope and depth of actual practice. After each decision, learners received clinical guidance (CG) based on current evidence and faculty recommendations. Clinical decisions were compared pre- and post-CG using a 2-tailed paired t-test to determine P values (P<.05 is significant). Rationales for clinical decisions were collected in real time. Data were collected between March 2022 and September 2022 and reported here as % relative improvement, P value. **Results:** Case 1 (n=335 hem/oncs) 62-yr-old man with a history of hypertension referred due to fatigue, back pain with pain score 5/10, and abnormal laboratory tests. Significant changes observed for: 1. Ordering appropriate tests to evaluate the patient (SPEP/SIFE, 13%, P<.001; serum LDH, 12%, P<.01, serum FLC assay, 9%, P<.01; PET-CT, 14%, P<.01; FBC, 8%, P<.01; FISH analysis, 8%, P<.01; CrCl, 14%, P<.01; chemistry panel, 7%, P<.01; bone marrow aspirate, 7%, P<.01, beta-2 microglobulin, 7%, P<.01; diagnosis of MM, 13%, P<.001). 2. Selecting an appropriate

treatment strategy for newly diagnosed MM (morphine sulfate slow release, 57%, P<.001; VRd, 19%, P<.001; daraVTd IV, 15%, P<.001; daraVTd sub-cut, 12%, P<.01; zoledronic acid, 60%, P<.001). 3. Counselling patients regarding potential outcomes and treatment-related adverse events (TrAEs) (order patient education, 25%, P<.01; order AE monitoring, 26%, P<.001). 4. Case 2 (n=335 hem/oncs) 75-yr-old man with a history of type 2 diabetes, atrial fibrillation, hypertension, and MM. Routine lab work 2 weeks ago returned abnormal; patient asked to come in to discuss the results. Significant changes observed for: 1. Ordering appropriate tests to evaluate the patient (SPEP/SIFE, 13%, P<.01; serum FLC assay, 10%, P<.05; PET-CT, 17%, P<.01; FBC, 8%, P<.05; FISH analysis, 10%, P<.05; chemistry panel, 9%, P<.05; bone marrow aspirate, 11%, P<.05; diagnosis of relapsed/refractory (R/R) MM, 34%, P<.001). 2. Selecting an appropriate treatment strategy for R/R MM (PomVd, 43%, P<.001; zoledronic acid, 51%, P<.001). 3. Counselling patients regarding potential outcomes and TrAEs (order patient education, 14%, P<.01; order AE monitoring, 15%, P<.01; at home blood sugar monitoring, 10%, P<.05) **Conclusions:** These results demonstrate the success of immersive, online VPS education that engages physicians in a practical learning experience in improving their performance in managing patients with MM.

Impact of melphalan staggered dosing prior to autologous hematopoietic cell transplantation for multiple myeloma patients

Catherine Hoang[1], Candido Chacon[1], Brendon Cornett[2], Tara Gregory[3], Danielle Smidt[1]

[1]Presbyterian St. Luke's Medical Center, Colorado Blood Cancer Institute, Sarah Cannon Cancer Network; [2]HCA Graduate Medical Education; [3]Colorado Blood Cancer Institute, Sarah Cannon Cancer Network, Denver, CO, USA

Introduction: Multiple myeloma (MM) is a hematologic malignancy characterized by the proliferation of plasma cells in the bone marrow. The standard of care treatment for eligible patients with newly diagnosed, symptomatic MM after induction therapy is conditioning with high-dose melphalan followed by autologous hematopoietic cell transplantation (auto-HCT). Currently, the standard melphalan dosing regimen is 100 mg/m^2 given on Day -2 and Day -1. However, due to melphalan's stability issues, preparation of this dosing strategy can cause increase cost and drug waste. To reduce high cost and waste associated with chemotherapeutic agents, Hematology/Oncology Pharmacy Association (HOPA) recommends cytotoxic agents be considered for dose rounding if within 5% to 10% of the prescribed dose. Due to melphalan's short stability and high cost, our hospital investigated dose rounding using a staggered melphalan dosing approach. The total ordered dose (200 mg/m^2) was rounded to the nearest vial size if the difference between the total dose and nearest vial size is less than or equal to 5%. Day -2 and Day -1 doses were determined by splitting the rounded total dose so that each day used an entire vial. **Methods:** This study is a single-center, retrospective chart review assessing the efficacy and safety of staggered melphalan dosing compared to standard melphalan dosing. Admitted patients receiving high-dose melphalan prior to auto-HCT from January 1st, 2021, through June 30th, 2022, were included. Patients with systemic light chain amyloidosis and patients receiving tandem auto-HCT were excluded. Data was obtained from patient electronic medical records and CIMBTR records. A cox regression was used to evaluate the time to neutrophil and platelet engraftment. Descriptive statistics were used to evaluate all other outcomes. This study is IRB exempted. **Results:** A total of 148 patients were included; 102 patients received staggered melphalan dosing and 46 patients received standard melphalan dosing. Doses were rounded between 0.5 to 5.7% and most doses were rounded down. Baseline characteristics were similar across both groups. There was not a significant difference in the median time to neutrophil engraftment (HR 0.98; p-value 0.93) nor platelet engraftment (HR 1.13; p-value 0.5). There was not a significant difference between the rate of mucositis, diarrhea, nausea, and vomiting. A significantly higher number of patients in the standard melphalan group developed sepsis (3 vs. 0; p-value 0.03). Rates of disease progression and mortality were similar between the two groups. Implementation of staggered melphalan dosing allowed our hospital to save 119 vials and ~$180,000 within the 1.5 years of this study. **Conclusions:** Staggered melphalan dosing is an effective and safe method and results in cost savings and waste reduction for transplant institutions.

Introduction: The treatment landscape of Multiple Myeloma (MM) has evolved in the last decade with the approval of many innovative drugs, improving patient survival. However, in low-resource regions such as Latin America (LA), the approval and access to novel therapies might be delayed, negatively impacting the outcomes of those patients. The MYLACRE study aimed to describe the MM population demographics and clinical characteristics, and

treatment strategy for newly diagnosed MM (morphine sulfate slow release, 57%, P<.001; VRd, 19%, P<.001; daraVTd IV, 15%, P<.001; daraVTd sub-cut, 12%, P<.01; zoledronic acid, 60%, P<.001). 3. Counselling patients regarding potential outcomes and treatment-related adverse events (TrAEs) (order patient education, 25%, P<.01; order AE monitoring, 26%, P<.001). 4. Case 2 (n=335 hem/oncs) 75-yr-old man with a history of type 2 diabetes, atrial fibrillation, hypertension, and MM. Routine lab work 2 weeks ago returned abnormal; patient asked to come in to discuss the results. Significant changes observed for: 1. Ordering appropriate tests to evaluate the patient (SPEP/SIFE, 13%, P<.01; serum FLC assay, 10%, P<.05; PET-CT, 17%, P<.01; FBC, 8%, P<.05; FISH analysis, 10%, P<.05; chemistry panel, 9%, P<.05; bone marrow aspirate, 11%, P<.05; diagnosis of relapsed/refractory (R/R) MM, 34%, P<.001). 2. Selecting an appropriate treatment strategy for R/R MM (PomVd, 43%, P<.001; zoledronic acid, 51%, P<.001). 3. Counselling patients regarding potential outcomes and TrAEs (order patient education, 14%, P<.01; order AE monitoring, 15%, P<.01; at home blood sugar monitoring, 10%, P<.05) **Conclusions:** These results demonstrate the success of immersive, online VPS education that engages physicians in a practical learning experience in improving their performance in managing patients with MM.

Introduction: Multiple myeloma (MM) is a hematologic malignancy characterized by the proliferation of plasma cells in the bone marrow. The standard of care treatment for eligible patients with newly diagnosed, symptomatic MM after induction therapy is conditioning with high-dose melphalan followed by autologous hematopoietic cell transplantation (auto-HCT). Currently, the standard melphalan dosing regimen is 100 mg/m^2 given on Day -2 and Day -1. However, due to melphalan's stability issues, preparation of this dosing strategy can cause increase cost and drug waste. To reduce high cost and waste associated with chemotherapeutic agents, Hematology/Oncology Pharmacy Association (HOPA) recommends cytotoxic agents be considered for dose rounding if within 5% to 10% of the prescribed dose. Due to melphalan's short stability and high cost, our hospital investigated dose rounding using a staggered melphalan dosing approach. The total ordered dose (200 mg/m^2) was rounded to the nearest vial size if the difference between the total dose and nearest vial size is less than or equal to 5%. Day -2 and Day -1 doses were determined by splitting the rounded total dose so that each day used an entire vial. **Methods:** This study is a single-center, retrospective chart review assessing the efficacy and safety of staggered melphalan dosing compared to standard melphalan dosing. Admitted patients receiving high-dose melphalan prior to auto-HCT from January 1st, 2021, through June 30th, 2022, were included. Patients with systemic light chain amyloidosis and patients receiving tandem auto-HCT were excluded. Data was obtained from patient electronic medical records and CIMBTR records. A cox regression was used to evaluate the time to neutrophil and platelet engraftment. Descriptive statistics were used to evaluate all other outcomes. This study is IRB exempted. **Results:** A total of 148 patients were included; 102 patients received staggered melphalan dosing and 46 patients received standard melphalan dosing. Doses were rounded between 0.5 to 5.7% and most doses were rounded down. Baseline characteristics were similar across both groups. There was not a significant difference in the median time to neutrophil engraftment (HR 0.98; p-value 0.93) nor platelet engraftment (HR 1.13; p-value 0.5). There was not a significant difference between the rate of mucositis, diarrhea, nausea, and vomiting. A significantly higher number of patients in the standard melphalan group developed sepsis (3 vs. 0; p-value 0.03). Rates of disease progression and mortality were similar between the two groups. Implementation of staggered melphalan dosing allowed our hospital to save 119 vials and ~$180,000 within the 1.5 years of this study. **Conclusions:** Staggered melphalan dosing is an effective and safe method and results in cost savings and waste reduction for transplant institutions.

Introduction: The treatment landscape of Multiple Myeloma (MM) has evolved in the last decade with the approval of many innovative drugs, improving patient survival. However, in low-resource regions such as Latin America (LA), the approval and access to novel therapies might be delayed, negatively impacting the outcomes of those patients. The MYLACRE study aimed to describe the MM population demographics and clinical characteristics, and

to profile the treatment landscape of LA MM patients. **Methods:** This was a retrospective and prospective non-interventional, multicenter study of MM patients from 5 LA countries. Patients aged ≥ 18 diagnosed with MM between January 1, 2016 and June 30, 2021 were included. Data were extracted from medical charts between August 2019 and June 2022 and a descriptive analysis was conducted. **Results:** A total of 1,029 patients from 22 reference centers were enrolled, with a median follow-up of 26.8 months. Two thirds (66.8%) had private health insurance coverage. The median age at diagnosis was 64 years and most patients were diagnosed as International Staging System (ISS) stage III (44%). End-organ damage signs and symptoms at diagnosis were reported in most of the patients, with half of them (45.2%) presenting anemia, 12.7% hypercalcemia, 22% renal disfunction and 80.2% bone lesions. Approximately 60% of the patients underwent a cytogenetic test and, of these, one-third (27%) had a cytogenetic abnormality. From the enrolled patients, 1,003 started the first line of therapy (LOT), 405 LOT2, 168 LOT3, 74 LOT4 and 20 LOT5, resulting in an attrition rate of approximately 23-34% from one LOT to the subsequent LOT. Most patients (69.9%) were eligible for stem cell transplant (SCT) upfront, but, of those, 26.8% did not receive it. The main reason was insufficient response, disease progression or death before SCT. Considering patients who underwent SCT, the majority in both private and public settings received a proteasome inhibitor (PI)-based therapy (60.6%, 40.8% respectively) and considering those who did not undergo SCT, the majority in the private setting received a PI-based therapy (58.6%), while in the public setting the majority received an immunomodulatory drug (IMiD) based therapy (53.7%). For LOT2, anti-CD38 based regimens were the most received in the private setting (31.9%) and PI-based regimens for the public setting (40.2%). The median progression-free survival (PFS) of LOT1 was 40 months, LOT2 15.9 months, LOT3 8.9 months, and later LOT 4.6 months. The median overall survival (OS) for all patients was 48.9 months. **Conclusions:** The attrition rate between subsequent LOTs is high and the pattern of treatment differs between private and public settings. The adoption of novel therapies in LA is still low compared with other regions in the world, and the unmet need is higher in earlier LOTs and for patients with no health insurance.

Response and survival outcomes of daratumumab, lenalidomide, bortezomib and dexamethasone (D-RVD) induction in transplant-eligible newly diagnosed multiple myeloma (NDMM) patients

Nisha Joseph[1], Jonathan Kaufman[1], Sagar Lonial[1], Craig Hofmeister[1], Madhav Dhodapkar[1], Vikas Gupta[1], Sara DiCamillo[1], Danielle Roberts[1], Lawrence Boise[1], Ajay Nooka[1]

[1]Winship Cancer Institute at Emory University, Atlanta, GA, USA

Introduction: The combination of lenalidomide, bortezomib, and dexamethasone (RVD) has been shown to be highly effective for both transplantation-eligible and -ineligible patients with newly diagnosed myeloma (NDMM). More recently, the addition of daratumumab (D) to RVd (D-RVd) in transplant-eligible NDMM patients was evaluated in the GRIFFIN trial (Voorhees et al) showing that sCR rates improved for D-RVd vs RVd. We present the largest cohort of patients consecutively treated with D-RVd induction therapy and the impact of D-RVd on long-term outcomes. **Methods:** 326 consecutive patients with newly diagnosed myeloma treated with D-RVd induction therapy from April 2018 until August 2022 were included in this analysis. Demographic and clinical characteristics and outcomes data were obtained from our institutional review board-approved myeloma database, and manual extraction. Responses and progression were evaluated per International Myeloma Working Group Uniform Response Criteria. **Results:** The cohort consisted of 181 (55.5%) males, 133 (41%) black. The median age was 64.3 (23.5-79.3) vs 59 (34.7-76.7) years, p< 0.05 for whites vs. black, respectively. 199 (65.2%) had IgG isotype, 64 (21.4%) had t(11;14), 17 (5.2%) had del 17p, 13 (4%) had t(4;14) 3 (1%) had t(14;16) and 5 (1.5%) had t(14;20). Altogether, 45 (13.8%) had high-risk disease, 52 (16%) had ISS stage 3 disease and 15 (4.6%) had R-ISS stage 3 disease. 84.6% received single agent maintenance with lenalidomide. The overall response rate was 99.7% after induction therapy [86.5% achieving a very good partial response or better (≥VGPR), 21.5% achieving complete response or better (≥CR)] and 99.3% after transplantation (95.6% achieving ≥VGPR and 42.8% achieving complete response or better (≥CR) after transplantation. The estimated 3-year progression-free survival was 91% at a median follow up of 17.1 months. This compares favorably to our historical cohort of RVD patients, where the 3-year PFS rate was 70%. The estimated 4-year overall survival was 92% at a median follow up of 17.3 months, again comparing favorably to our historical cohort of RVD patients with a 4-year OS of 79%. **Conclusions:** D-RVd is a highly effective induction regimen that delivers high quality response rates (≥VGPR) in close to 95% of patients after transplantation. In the absence of phase 3 data supporting D-RVd as induction regimen, this study provides the evidence of benefit of adding daratumumab to RVd in increasing depth of response, and provides an early glimpse of the promising PFS and OS particularly when compared to our historical cohort. This is the largest cohort of patients treated with D-RVd reported to date, and demonstrates the superiority of quadruplets in treating newly diagnosed multiple myeloma.

More recently, the addition of daratumumab (D) to RVd (D-RVd) in transplant-eligible NDMM patients was evaluated in the GRIFFIN trial (Voorhees et al) showing that sCR rates improved for D-RVd vs RVd. We present the largest cohort of patients consecutively treated with D-RVd induction therapy and the impact of D-RVd on long-term outcomes. **Methods:** 326 consecutive patients with newly diagnosed myeloma treated with D-RVd induction therapy from April 2018 until August 2022 were included in this analysis. Demographic and clinical characteristics and outcomes data were obtained from our institutional review board-approved myeloma database, and manual extraction. Responses and progression were evaluated per International Myeloma Working Group Uniform Response Criteria. **Results:** The cohort consisted of 181 (55.5%) males, 133 (41%) black. The median age was 64.3 (23.5-79.3) vs 59 (34.7-76.7) years, p< 0.05 for whites vs. black, respectively. 199 (65.2%) had IgG isotype, 64 (21.4%) had t(11;14), 17 (5.2%) had del 17p, 13 (4%) had t(4;14) 3 (1%) had t(14;16) and 5 (1.5%) had t(14;20). Altogether, 45 (13.8%) had high-risk disease, 52 (16%) had ISS stage 3 disease and 15 (4.6%) had R-ISS stage 3 disease. 84.6% received single agent maintenance with lenalidomide. The overall response rate was 99.7% after induction therapy [86.5% achieving a very good partial response or better (≥VGPR), 21.5% achieving complete response or better (≥CR)] and 99.3% after transplantation (95.6% achieving ≥VGPR and 42.8% achieving complete response or better (≥CR) after transplantation. The estimated 3-year progression-free survival was 91% at a median follow up of 17.1 months. This compares favorably to our historical cohort of RVD patients, where the 3-year PFS rate was 70%. The estimated 4-year overall survival was 92% at a median follow up of 17.3 months, again comparing favorably to our historical cohort of RVD patients with a 4-year OS of 79%. **Conclusions:** D-RVd is a highly effective induction regimen that delivers high quality response rates (≥VGPR) in close to 95% of patients after transplantation. In the absence of phase 3 data supporting D-RVd as induction regimen, this study provides the evidence of benefit of adding daratumumab to RVd in increasing depth of response, and provides an early glimpse of the promising PFS and OS particularly when compared to our historical cohort. This is the largest cohort of patients treated with D-RVd reported to date, and demonstrates the superiority of quadruplets in treating newly diagnosed multiple myeloma.

Hematology/Oncology, German Cancer Research Center (DKFZ), Heidelberg, Germany; [4]GMMG Study Group at University Hospital Heidelberg, Heidelberg, Germany; [5]National Center for Tumor Diseases (NCT), Heidelberg, Germany; [6]Internal Medicine V, GMMG Study Group at University Hospital Heidelberg, Heidelberg, Germany

Introduction: In transplant-eligible patients with newly diagnosed multiple myeloma (MM), induction therapy followed by high-dose chemotherapy (HDCT) and peripheral blood stem cell (PBSC) transplantation is standard-of-care. Modern triplet and quadruplet regimen are commonly used as induction therapy, but their impact on PBSC mobilization and collection outcomes remain incompletely understood. This study evaluates the impact of prolonged lenalidomide induction and isatuximab- or elotuzumab-containing quadruplet induction therapies on PBSC mobilization and collection. **Methods:** 179 transplant-eligible patients with newly diagnosed MM treated within the randomized phase III clinical trials GMMG-HD6 (NCT02495922) and GMMG-HD7 (NCT03617731) at a single academic center were included. The median age at diagnosis was 59 (range 26-71). 62% of patients were male, 65% showed IgG myeloma, 64% kappa light chain restriction, and 28% presented with high-risk cytogenetics. Patients were evaluated according to PBSC mobilization and collection parameters such as overall collection result, CD34+ cell levels in peripheral blood, leukapheresis (LP) delays and overall number of LP sessions as well as the rate of rescue mobilization with plerixafor. Patients underwent four different induction regimen: Lenalidomide, bortezomib, and dexamethasone (RVd, six 21-day cycles, n=44), isatuximab-RVd (six 21-day cycles, n=35), RVd (four 21-day cycles, n=51), or elotuzumab-RVd (four 21-day cycles, n=49). **Results:** Patients' characteristics were well balanced among groups. Collection failures, defined by the inability to collect three sufficient PBSC transplants, were rare (n=3, 2%) with no occurence in the isatuximab-RVd and elotuzumab-RVd groups. Intensified induction with six 21-day cycles of RVd in comparison to four 21-day cycles of RVd did not hamper overall numbers of collected PBSC (9.7 x10^6/kg bw, IQR 3.1, versus 10.5 x10^6/kg bw, IQR 3.9, p=0.331). Plerixafor was more commonly used after six cycles versus four cycles of RVd (16% versus 8%). No negative impact on overall PBSC collection was observed upon addition of elotuzumab to RVd (10.9 x10^6/kg bw, IQR 3.8 versus 10.5 x10^6/kg bw, IQR 3.9, p=0.915). Patients treated with isatuximab-RVd (six cycles) had overall lower numbers of collected stem cells as compared to patients receiving RVd (six cycles) induction (8.8 x10^6/kg bw, IQR 1.8 versus 9.7 x10^6/kg bw, IQR 3.1, p=0.801), without experiencing more LP delay or significantly increased numbers of LP sessions in a multivariable logistic regression analysis. Plerixafor use was more common after isatuximab plus RVd versus RVd alone (34% versus 16%). **Conclusions:** We provide the first detailed data on stem cell collection after induction with isatuximab plus RVd. These data demonstrate that stem cell collection is feasible after prolonged induction with isatuximab-RVd without collection failures. Addition of elotuzumab to RVD as well as prolonged induction with RVd did not affect stem cell yield.

Treatment access among Black and White older adults with multiple myeloma: A SEER-Medicare analysis

Matthew LeBlanc[1], Christopher Jensen[2], Xi Zhou[3], Jennifer Lund[4], Christoher Baggett[4], Laura Green[3], Kuo Tzy-Mey[3], Bradford Jackson[3], Kathryn Reeder-Hayes[2]

[1]School of Nursing, University of North Carolina at Chapel Hill; [2]School of Medicine, University of North Carolina at Chapel Hill; [3]UNC Lineberger Comprehensive Cancer Center; [4]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina At Chapel Hill

Introduction: Multiple myeloma (MM) is an incurable cancer of the plasma cells that has seen incredible treatment innovation over the past two decades though not all groups have benefited equally from these improvements. This study explores trends in MM treatment access among Black and White older adults in the United States. **Methods:** Black and White older adults diagnosed with MM (2007-2017) were identified in the SEER-Medicare database. Individuals were required to have continuous Medicare Parts A and B coverage 12 months prior to and following diagnosis (or until death), and Part D coverage 12 months following diagnosis (or until death). Primary outcomes were receipt of any MM treatment (TX) within 12 months of diagnosis, and receipt of any MM care at an NCI cancer center (NCI CC) within 12 months of diagnosis (a proxy for early access to MM specialists). Patients were categorized by year of diagnosis into 3 roughly equal time periods; 2007-10, 2011-14, 2015-17. We used standardized mortality ratio weighting to standardize the distribution of age, sex, and pre-diagnosis Charlson comorbidity score across racial groups with White race as reference. Modified Poisson regression was used to estimate change (risk difference) across time periods stratified by race, and differences by race within time periods. **Results:** Our cohort consisted of 1,649 Black and 9,017 White older adults with MM. The percentage of White individuals receiving any TX increased from 62.8 to 71.0% (2011-14 vs 2007-10, RD = 8.3, [95% CI: 5.9, 10.6]) to 73.4% (2015-17 vs 2011-14, RD = 2.4 [0.2, 4.6]). The percentage of Black individuals receiving any TX increased from 56.9 to 59.4%, (2011-14 vs 2007-10, RD= 2.5, [-4.4, 9.4]) to 64.7%, (2015-17 vs 2011-14, RD = 5.3, [-1.4, 1.2]). A lower percentage of Black individuals received treatment compared with White individuals in all time periods; 2007-10: RD = 5.9 (0.3, 11.5), 2011-14: RD = 11.6 (6.9, 16.4), 2015-17: RD 8.8 (3.7, 13.9). The percentage of White individuals receiving any care at an NCI CC increased from 21.5 to 28.1% (2011-14 vs 2007-10, RD = 6.6, [4.4, 8.8]) to 34.9% (2015-17 vs 2011-14, RD = 6.8 [4.6, 9.1]). The percentage of Black individuals receiving any care at an NCI CC increased from 16.4 to 19.2%, (2011-14 vs 2007-10, RD= 2.8, [-2.3, 7.9]) to 22.1%, (2015-17 vs 2011-14, RD = 3.0, [-2.5, 8.4]). A lower percentage of Black individuals received care at NCI CC compared with White individuals in all time periods; 2007-10: RD = 5.0 (0.9, 9.1), 2011-14: RD = 8.8 (5.0, 12.6), 2015-17: RD 12.7 (8.2, 17.2). **Conclusions:** Overtime more people are enjoying access to MM TX and care at NCI CC, but these increases have not been experienced

Introduction: Despite the development of effective agents for multiple myeloma (MM), managing patients with high-risk MM (HRMM) remains challenging. High-dose treatment followed by autologous stem cell transplantation (ASCT) is considered the frontline treatment for transplant-eligible patients with HRMM. This study aimed to compare the efficacy of two conditioning regimens, high-dose melphalan (HDMEL; 200 mg/m^2) and busulfan plus melphalan (BUMEL), for upfront ASCT in newly diagnosed patients with MM and high-risk features. **Methods:** This study retrospectively collected the data of patients diagnosed with MM between May 2005 and June 2021 who received ASCT with BUMEL or HDMEL conditioning from 12 institutions that participated in the KMM 2015 trial. **Results:** A total of 221 patients underwent ASCT between May 2005 and June 2021, and among them, 79 had high-risk cytogenetic abnormalities. In patients with high-risk cytogenetics, BUMEL showed a tendency toward longer overall survival (OS) and progression-free survival (PFS) compared to HDMEL (median OS: not reached vs. 53.2 months; P = 0.091; median PFS: not reached vs. 31.7 months; P = 0.062). Furthermore, multivariate analysis revealed that BUMEL was significantly associated with improved PFS (hazard ratio = 0.37, 95% confidence interval = 0.15–0.89, P = 0.026). Additionally, we compared BUMEL with HDMEL in patients with other high-risk features, such as high lactate dehydrogenase level, extramedullary disease, and poor response to frontline therapy. Notably, among patients with less than a very good partial response (VGPR) to frontline therapy, the BUMEL group had a significantly longer median PFS compared to the HDMEL group (55.1 vs. 17.3 months, respectively; P = 0.011). **Conclusions:** These findings suggest that BUMEL is an effective conditioning regimen for upfront ASCT in MM patients with high-risk cytogenetics, and it may be more suitable than HDMEL for patients with less than a VGPR to frontline therapy.

P-145

Early M protein immune reconstitution is a good prognostic marker for patients with high-risk cytogenetic multiple myeloma after autologous hematopoietic stem cell transplantation

Huihui Zhu[1], Juan Li[1]

[1]First Affiliated Hospital of Sun Yat-sen University

Introduction: The presence of transient monoclonal immunoglobulins (i.e. M-protein immune reconstitution) in serum immunofixation electrophoresis after autologous hematopoietic stem cell transplantation in patients with multiple myeloma has been reported, and patients with high-risk cytogenetics tend to have poor prognosis; the purpose of this paper is to investigate the impact of post-transplant M-protein immune reconstitution on the prognosis of patients with high-risk cytogenetic multiple myeloma **Methods:** To retrospectively analyze the clinical data of 290 newly diagnosed multiple myeloma patients from August 1, 2008 to July 31, 2021 at the First Affiliated Hospital of Sun Yat-sen University, all of whom underwent sequential autologous hematopoietic stem cell transplantation after induction therapy, and to analyze and compare the clinical characteristics and prognostic survival of patients with and without M-protein immune reconstitution **Results:** M protein immune reconstitution was observed in 25.9% (75/290 patients), the most common type of immunoglobulin was IgG-λ. The median time to obtain reconstruction was 3 months (1-38 months) and the median duration was 4 months (1-39 months) after transplantation, and there were no statistical differences in disease stage, tumor load and cytogenetics between the immune reconstituted and unreconstructed groups. The CR rate and MRD negativity were higher in the M protein immune reconstitution group (P=0.019, 85.3% vs 69.3%, P=0.014, 81.9% vs 66.5%), and although there were no statistical differences in PFS and OS between the M protein immune reconstitution group and the group without immune reconstruction, the overall median survival time was longer in the M protein immune reconstruction group (P=0.137, 80m vs 72m; P=0.800, 49m vs 33m).Among patients in the cytogenetic high-risk group, access to M protein immune reconstitution predicted better PFS and OS (P=0.011, 80m vs 31m; P=0.079, 54m vs 16m).Also in R-ISS stage III patients, PFS and OS were better in patients who obtained M protein immune reconstitution than in those who did not (P=0.008, 80m vs 20m; P=0.044, 52m vs 26m). **Conclusions:** Better prognosis in immune reconstructed patients may be associated

by all race groups equally. Black/White disparities were noted at each time period and while the percentage of White individuals receiving TX and care at an NCI CC saw significant increases over time, Black individuals, already disadvantaged compared to White individuals, have seen more modest nonsignificant increases over time.

Early M protein immune reconstitution is a good prognostic marker for patients with high-risk cytogenetic multiple myeloma after autologous hematopoietic stem cell transplantation

Huihui Zhu[1], Juan Li[1]

[1]First Affiliated Hospital of Sun Yat-sen University

Introduction: The presence of transient monoclonal immunoglobulins (i.e. M-protein immune reconstitution) in serum immunofixation electrophoresis after autologous hematopoietic stem cell transplantation in patients with multiple myeloma has been reported, and patients with high-risk cytogenetics tend to have poor prognosis; the purpose of this paper is to investigate the impact of post-transplant M-protein immune reconstitution on the prognosis of patients with high-risk cytogenetic multiple myeloma **Methods:** To retrospectively analyze the clinical data of 290 newly diagnosed multiple myeloma patients from August 1, 2008 to July 31, 2021 at the First Affiliated Hospital of Sun Yat-sen University, all of whom underwent sequential autologous hematopoietic stem cell transplantation after induction therapy, and to analyze and compare the clinical characteristics and prognostic survival of patients with and without M-protein immune reconstitution **Results:** M protein immune reconstitution was observed in 25.9% (75/290 patients), the most common type of immunoglobulin was IgG-λ. The median time to obtain reconstruction was 3 months (1-38 months) and the median duration was 4 months (1-39 months) after transplantation, and there were no statistical differences in disease stage, tumor load and cytogenetics between the immune reconstituted and unreconstructed groups. The CR rate and MRD negativity were higher in the M protein immune reconstitution group (P=0.019, 85.3% vs 69.3%, P=0.014, 81.9% vs 66.5%), and although there were no statistical differences in PFS and OS between the M protein immune reconstitution group and the group without immune reconstruction, the overall median survival time was longer in the M protein immune reconstruction group (P=0.137, 80m vs 72m; P=0.800, 49m vs 33m).Among patients in the cytogenetic high-risk group, access to M protein immune reconstitution predicted better PFS and OS (P=0.011, 80m vs 31m; P=0.079, 54m vs 16m).Also in R-ISS stage III patients, PFS and OS were better in patients who obtained M protein immune reconstitution than in those who did not (P=0.008, 80m vs 20m; P=0.044, 52m vs 26m). **Conclusions:** Better prognosis in immune reconstructed patients may be associated

by all race groups equally. Black/White disparities were noted at each time period and while the percentage of White individuals receiving TX and care at an NCI CC saw significant increases over time, Black individuals, already disadvantaged compared to White individuals, have seen more modest nonsignificant increases over time.

Introduction: Despite the development of effective agents for multiple myeloma (MM), managing patients with high-risk MM (HRMM) remains challenging. High-dose treatment followed by autologous stem cell transplantation (ASCT) is considered the frontline treatment for transplant-eligible patients with HRMM. This study aimed to compare the efficacy of two conditioning regimens, high-dose melphalan (HDMEL; 200 mg/m^2) and busulfan plus melphalan (BUMEL), for upfront ASCT in newly diagnosed patients with MM and high-risk features. **Methods:** This study retrospectively collected the data of patients diagnosed with MM between May 2005 and June 2021 who received ASCT with BUMEL or HDMEL conditioning from 12 institutions that participated in the KMM 2015 trial. **Results:** A total of 221 patients underwent ASCT between May 2005 and June 2021, and among them, 79 had high-risk cytogenetic abnormalities. In patients with high-risk cytogenetics, BUMEL showed a tendency toward longer overall survival (OS) and progression-free survival (PFS) compared to HDMEL (median OS: not reached vs. 53.2 months; P = 0.091; median PFS: not reached vs. 31.7 months; P = 0.062). Furthermore, multivariate analysis revealed that BUMEL was significantly associated with improved PFS (hazard ratio = 0.37, 95% confidence interval = 0.15–0.89, P = 0.026). Additionally, we compared BUMEL with HDMEL in patients with other high-risk features, such as high lactate dehydrogenase level, extramedullary disease, and poor response to frontline therapy. Notably, among patients with less than a very good partial response (VGPR) to frontline therapy, the BUMEL group had a significantly longer median PFS compared to the HDMEL group (55.1 vs. 17.3 months, respectively; P = 0.011). **Conclusions:** These findings suggest that BUMEL is an effective conditioning regimen for upfront ASCT in MM patients with high-risk cytogenetics, and it may be more suitable than HDMEL for patients with less than a VGPR to frontline therapy.

Early M protein immune reconstitution is a good prognostic marker for patients with high-risk cytogenetic multiple myeloma after autologous hematopoietic stem cell transplantation

Huihui Zhu[1], Juan Li[1]

[1]First Affiliated Hospital of Sun Yat-sen University

Introduction: The presence of transient monoclonal immunoglobulins (i.e. M-protein immune reconstitution) in serum immunofixation electrophoresis after autologous hematopoietic stem cell transplantation in patients with multiple myeloma has been reported, and patients with high-risk cytogenetics tend to have poor prognosis; the purpose of this paper is to investigate the impact of post-transplant M-protein immune reconstitution on the prognosis of patients with high-risk cytogenetic multiple myeloma **Methods:** To retrospectively analyze the clinical data of 290 newly diagnosed multiple myeloma patients from August 1, 2008 to July 31, 2021 at the First Affiliated Hospital of Sun Yat-sen University, all of whom underwent sequential autologous hematopoietic stem cell transplantation after induction therapy, and to analyze and compare the clinical characteristics and prognostic survival of patients with and without M-protein immune reconstitution **Results:** M protein immune reconstitution was observed in 25.9% (75/290 patients), the most common type of immunoglobulin was IgG-λ. The median time to obtain reconstruction was 3 months (1-38 months) and the median duration was 4 months (1-39 months) after transplantation, and there were no statistical differences in disease stage, tumor load and cytogenetics between the immune reconstituted and unreconstructed groups. The CR rate and MRD negativity were higher in the M protein immune reconstitution group (P=0.019, 85.3% vs 69.3%, P=0.014, 81.9% vs 66.5%), and although there were no statistical differences in PFS and OS between the M protein immune reconstitution group and the group without immune reconstruction, the overall median survival time was longer in the M protein immune reconstruction group (P=0.137, 80m vs 72m; P=0.800, 49m vs 33m).Among patients in the cytogenetic high-risk group, access to M protein immune reconstitution predicted better PFS and OS (P=0.011, 80m vs 31m; P=0.079, 54m vs 16m).Also in R-ISS stage III patients, PFS and OS were better in patients who obtained M protein immune reconstitution than in those who did not (P=0.008, 80m vs 20m; P=0.044, 52m vs 26m). **Conclusions:** Better prognosis in immune reconstructed patients may be associated

with the acquisition of a deeper response, but in high-risk patients, early acquisition of immune reconstitution may suggest a better prognosis.

P-146

MASS-4 is more suitable than MASS-3 for prognostic stratification in transplant-eligible patients with newly diagnosed multiple myeloma

Juan Li[1], Fan Yang[1]

[1]First Affiliated Hospital of Sun Yat-sen University

Introduction: In 2022, Mayo Clinic proposed the Mayo Additive Staging System (MASS), a new staging system for patients with newly diagnosed multiple myeloma (NDMM). Based on the number of risk factors (ISS III, elevated lactate dehydrogenase, 1q gain/ amplification, high-risk IgH translocations, chromosome 17 abnormalities), they were divided into the 3-tier MASS (MASS-3) (no, 1, ≥2 high-risk factors for stage I, II, III, respectively) and 4-tier MASS (MASS-4) (no, 1, 2, ≥3 high-risk factors for stage I, II, III, IV, respectively). Real-world studies have shown that MASS-3 and MASS-4 are suitable for prognostic stratification in Chinese patients with NDMM, but there is no clear evidence of their utility in transplant-eligible patients with NDMM. **Methods:** A retrospective analysis of the clinical data of 215 NDMM patients who received "induction therapy-autologous hematopoietic stem cell transplantation (ASCT)" in our center was performed. **Results:** The median progression-free survival (PFS) of MASS-3 I, II, and III was 77.7, 87.7, and 50.5 months, respectively(P=0.011), and the median overall survival (OS) was not reached, 109.6, and 69.7 months, respectively(P=0.003). The PFS and OS of patients with MASS-3 III were significantly shorter than those of stage I (P< 0.05). The median PFS of MASS-4 I, II, III, and IV was 77.7, 87.7, 52.6, and 34.5 months, respectively (P=0.004), and the median OS was not reached, 109.6, 106.0, and 40.6 months, respectively (P< 0.001). The PFS and OS of patients with MASS-4 III were significantly shorter than those of stage I (P< 0.05). The PFS of patients with MASS-4 IV was significantly shorter than that of stage I, II, or III (P < 0.001). The OS of stage IV was significantly shorter than that of stage I or II (P < 0.01), and tended to be shorter than that of III (P =0.06). In patients with single ASCT, different ages, and different induction regimens, the prognostic stratification of MASS-4 was also better than that of MASS-3. However, there was no significant difference in PFS and OS between different MASS-3 or MASS-4 stages in patients with tandem ASCT. **Conclusions:** Among transplant-eligible patients with NDMM, the prognostic stratification value of MASS-4 was better than that of MASS-3, particularly distinguishing high-risk patients with poor prognosis. Compared with single ASCT, tandem ASCT may overcome the poor prognosis of high-risk MASS patients.

Obtaining M protein immune reconstitution as soon as possible after tandem autologous hematopoietic stem cell transplantation improves the prognosis of patients with newly diagnosis multiple myeloma

Huihui Zhu[1], Juan Li[1]

[1]First Affiliated Hospital of Sun Yat-sen University

Introduction: In the era of new drug therapy, autologous hematopoietic stem cell transplantation after induction therapy is the standard of care for patients with multiple myeloma, and Tandem autologous hematopoietic stem cell transplantation is a treatment option to improve the prognosis of patients with high-risk cytogenetics, and obtaining M protein immune reconstitution as soon as possible after double transplantation can further improve the survival of such patients. **Methods:** A total of 12 patients with newly diagnosed multiple myeloma diagnosed from June 1, 2019 to April 30, 2021 at the First Affiliated Hospital of Sun Yat-sen University were included, and all patients underwent tandem autologous hematopoietic stem cell transplantation after induction therapy containing bortezomib, and the prognostic survival of patients who obtained M-protein reconstitution after transplantation was analyzed **Results:** 58.3% (7/12) of patients obtained M protein immune reconstitution after Tandem transplantation, the most common type of M protein was IgG-type M protein, the median time to obtain M protein immune reconstitution was 3 months (2-9 months) after Tandem transplantation, the median duration of reconstitution was 3 months (3-6 months), and all patients were R-ISS stage II-III, 83.3% (10/12) of patients had high-risk cytogenetics, all patients achieved at least VGPR efficacy after transplantation, with a higher CR rate in the M protein immune reconstitution group (71.4% vs 60.0%, P=0.679), although not statistically significant, and a median survival time of 2 years in the immune reconstitution group **Conclusions:** Tandem transplantation is a treatment option to improve prognosis in patients with high-risk cytogenetic multiple myeloma, and patients who received M protein immune reconstitution after Tandem transplantation significantly improved survival time.

P-148

On-demand plerixafor added to high-dose cyclophosphamide and pegfilgrastim in the mobilization of patients with multiple myeloma: high effectiveness and affordable cost

Liqiong Hou[1], Juan Li[1]

[1]First Affiliated Hospital of Sun Yat-sun University

Introduction: Upfront single or tandem autologous stem cell transplantation(ASCT) still represents an integral part of treatment for patients with multiple myeloma. It is important to collect enough stem cells for two transplants in the first mobilization.The combination of high-dose cyclophosphamide(CTX) (3g/m^2) plus Filgrastim(FIL) and on-demand plerixafor has been considered the

effective method as mobilization regimen, but FIL requires daily, multi-injection administration.We adopted a mobilization regimen with CTX combination pegfilgrastim (PEG) and on-demand plerixafor, allowing for a single injection given the long half-life and slow elimination of PEG. Here, we performed a real-world analysis to evaluate the efficacy and cost of high-dose CTX combination PEG and on-demand plerixafor for mobilization in MM patients. **Methods:** We retrospectively compared 340 patients whith MM mobilized between August 2008 and December 2022 using the following mobilization strategies:CTX+PEG+/-Plerixafor(n=60), CTX+ PEG (n=91), CTX+ FIL(n=169), FIL+Plerixafor(n=20). Then the stem cell mobilization and collection results of the four groups were compared **Results:** Mobilization with CTX+PEG+/-Plerixafor resulted in a significantly higher total CD34+ cells collected (8.81×10^6/kg) compared to patients mobilized with other mobilization regimens: CTX+PEG(5.47×10^6/kg; p<0.001), CTX+FIL (4.65×10^6/kg; p<0.001), FIL+Plerixafor(2.73×10^6/kg; p<0.001). Day1+Day 2 CD34+ cells collected were higher in CTX+PEG+/- Plerixafor group too.(CTX+PEG+/- Plerixafor, 7.87×10^6/kg vs. CTX+PEG, 4.96×10^6/kg vs. CTX+ FIL, 3.92×10^6/kg vs FIL+Plerixafor, 2.425×10^6/kg) (p<0.001).The percentage of patients who achieved $>6\times10^6$/kg in CTX+PEG+/- Plerixafor group are significantly higher in CTX+PEG+/- Plerixafor group (74.6%) than other mobilization regimens: CTX+ PEG (44.9%; p<0.001), CTX+FIL (37.3%; p<0.001) , FIL+Plerixafor (15%; p<0.00) . Apheresis sessions were fewer in CTX+PEG+/- Plerixafor group (CTX+PEG+/- Plerixafor 2 vs CTX+PEG 3 vs CTX+FIL 3 vs FIL+Plerixafor 4) (p<0.001). Patients proceeded to ASCT with a mean of 2.94 (2.25, 4.77) $\times10^6$/kg CD34+cell infused for CTX+PEG+/- Plerixafor, 2.94 (2.37, 4.24) infused for CTX+PEG, 2.61 (2.31, 2.88) infused for FIL+Plerixafor, 3.17 (2.11, 4.90) infused for CTX+PEG (p=0.057). The median time to neutrophil and platelet engraftment not different in the four groups. Total costs of a mobilizing strategy using CTX+PEG+/- Plerixafor was significant lower ($5670.64) compared to G-CSF+Plerixafor group($11098.61), and significant higher than CTX+PEG group ($3842.23)and CTX+G-CSF group($3727.82) (p<0.001) . The incidence of neutropenic fever not different in the CTX+PEG+/-Plerixafor group(4%), CTX+PEG group (10%) and CTX+ FIL group (18%) (p=0.051). There was no patients suffered with neutropenic fever in FIL+Plerixafor **Conclusions:** Given higher rates of successful mobilization, affordable cost and toxicity, on-demand plerixafor added to high-dose CTX and PEG may be preferable in myeloma patients.

Follow-up of transplant-eligible multiple myeloma received Busulfan-based conditioing versus high-dose melphalan

Sung-Nam Lim[1], Beyong-Sok Sohn[2]

[1]Inje University College of Medicine, Haeundae Paik Hospital;
[2]Sanggye Paik Hospital, Inje University College of Medicine

Introduction: We previously reported that there was no difference in PFS between the two groups receiving conditioning using busulfan-based and high-dose melphalan. These results showed that busulfan-based conditioning has high efficacy with manageable adverse events. So, we followed up on the previously published data and conducted additional analyses focusing on biochemical and clinical relapse-related events. This retrospective study was performed to investigate the effectiveness and safety of busulfan, cyclophosphamide, and etoposide (BuCyE) versus high-dose melphalan, followed by ASCT. **Methods:** A total of 35 patients who had been treated with remission induction for bortezomib, thalidomide, and dexamethasone (VTD) were enrolled between March 2016 and September 2021. The median age of enrolled patients was 57 years, ranging from 47 to 67 years. The conditioning regimens were as follows, the busulfan-based regimen was composed of busulfan 3.2 mg/kg from days -7 to days -5, etoposide 200 mg/m^2 from days -5 to days -4, cyclophosphamide 50 mg/m^2 from days -3 to days -2 and HEMEL conditioning regimen consisted of melphalan from 140 mg/m^2 to 200 mg/m^2. **Results:** Revised international staging system (R-ISS) was shown as follows; stage I with 0 in BuCyE vs. 27.2% in HD-MEL, stage II with 84.6% in BuCyE vs. 68.1% in HD-MEL, and 15.4% in BuCyE vs. 4.5%, respectively. The overall response rate before ASCT was 100% in both groups, including 76.9% in BuCyE and 63.6% in HDMEL with more than very good partial response, and 30.8% in BuCyE versus 40.9% in HDMEL with complete response, respectively. The median follow-up for the group was 38 months. The 3-year progression-free survival (PFS) was 51.2% for the HDMEL group versus 61.5% for the BuCyE group. PFS was analyzed by dividing it into biochemical relapse and clinical relapse. When disease progression is limited to clinical relapse, the median PFS was 56.8 months in HDMEL (95% CI, 26.1 to 87.4 months) and 38.3 months in BuCyE (95% CI, 27.9 to 48.6 months) (P=0.611). If an event of PFS contained both biochemical relapse and clinical relapse the median PFS was 31.3 months in HDMEL (95% CI, 26.8 to 62.8 months) and 38.3 months in BuCyE (95% CI, 27.9 to 48.6 months) (P=0.877). Five-year overall survival rate was 76.1% in HDMEL versus 100% in BuCyE (P=0.168). The average time from ASCT to leukocyte recovery (≥ 1,000/mm^3 of absolute neutrophil count) and platelet recovery (≥50,000/mm^3 of platelet count) is as follows: 11 days in HDMEL versus 12 days in BuCyE (P=0.101) and 39 days in HDMEL versus 34 days in BuCyE (P=0.840), respectively. Among the patients who did not achieve complete remission (CR) before ASCT, the proportion of patients who achieved CR after ASCT was 46% (6/13) in HDMEL versus 50% (4/8) in BuCyE. **Conclusions:** Our results of the follow-up study showed that a busulfan-based conditioning regimen of BuCyE could be expected to prolong PFS and survival through secondary treatment compared to the high-dose melphalan conditioning regimen.

Autologous stem cell transplantation (ASCT) is still crucial for multiple myeloma (MM) patients with undetectable minimal residual disease after induction treatment

Wenqiang Yan[1], Jiahui Liu[2], Huishou Fan[2], Jingyu Xu[1], Jian Cui[2], Lugui Qiu[1], Dehui Zou[1], Gang An[1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China; [2]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College

Introduction: Attaining undetectable minimal residual disease (MRD) is the current therapeutic goal for multiple myeloma (MM). But there is a current lack of data regarding the clinical benefit of autologous stem cell transplantation (ASCT) for myeloma patients achieving early MRD-negative status after induction treatment, in addition to the interaction of longitudinal MRD status with ASCT. **Methods:** The present study included 407 transplant-eligible MM patients with available MRD status from the National Longitudinal Cohort of Hematological Diseases in China (NCT04645199), of whom 147 (34.4%) achieved early undetectable MRD and 182 (44.7%) received ASCT. **Results:** Early MRD-negative status was associated with a lower risk of disease progression (HR=0.447; 95%CI, 0.333-0.600; P< 0.001) and death (HR=0.473; 95%CI, 0.320-0.700; P< 0.001). Of note, patients who achieved undetectable MRD early still benefitted from ASCT, with a remarkable improvement in the median MRD-negative duration (33.5 to 58.0 months, P< 0.001), progression-free survival (PFS; 46.0 to 88.3 months, P< 0.001), and overall survival (OS; 76.4 months to not reached, P=0.003). These clinical benefits were more pronounced in patients with aggressive features (high-risk cytogenetic abnormalities or high tumor burden) other than in standard-risk patients. Similar results were observed in patients with detectable MRD after induction treatment. Additionally, we identified four MRD-status transformation patterns following ASCT, which were strongly correlated with diverse survival outcomes (P< 0.001). **Conclusions:** These findings emphasize the crucial role of ASCT in myeloma patients regardless of early MRD status, especially for high-risk patients. Longitudinal MRD conversion after ASCT also has a significant impact on risk stratification.

Introduction: Multiple myeloma is a relapsing remitting type of hematological cancer with no long term cure and heterogeneous outcomes. Presenting features impacts outcomes and varies across different ethnic and geographic regions. Differences with respect to incidence and outcomes in the African American population are well documented. Earlier studies from India have reported young age, late stages of the diseases and high incidence of myeloma defining events. We looked at consecutive cohort of patients with newly diagnosed myeloma over a year at a tertiary cancer institute to see the demographic and presenting characteristics. **Methods:** We did a retrospective analysis of all consecutive newly diagnosed patients with Multiple myeloma between January 2017 and December 2017. Data was collected from the electronic medical record. SPSSV22 was used for descriptive analysis. **Results:** A total of 254 newly diagnosed patients were registered at our hospital in the specified study period. Median age of study population was 57.2 years (range 26 to 79) and 168 (66.1%) were male. Comorbidities were reported in 109(42.9%) patients, mainly hypertension in 66 (60%),diabetes in 43 (39.4%). ECOG performance status was 2 or more in 143 (56.4%) patients. Most common symptom at diagnosis was bone pain, mostly backache, seen in 61.4% patients and 11 (4.4%) patients presented with paraparesis due to cord compression. Bone lesions were detected on imaging in 220 (86.6%), renal involvement in 74 (29.4%), anemia in 142 (55.9%) and hypercalcemia in 42 (16.5%). Fifteen (6%) presented with severe renal failure requiring dialysis. Median Hb was 9.6gm/dl (range 2.8 to 15.8), Median calcium was 9.45mg/dl (range 5.5 to 16.18) and median creatinine was 1.2mg/dl (range 0.6 to 21). The Imaging modality used was skeleton survey in 25.1%, low dose CT in 18.1%, MRI in 38.7% and PET-CT in 18.1%. 62(24.4%) patients had evidence of paramedullary soft tissue plasmacytoma. ISS stage was I in only 44 (17.7%) while ISS-III was present in 115 (46.4%) patients. LDH was elevated in 96 (37.8%) patients. Cytogenetics revealed hyperdiploidy in 98 out of 234 tested for same (38.5%) and high risk IgH translocation (t(4;14), (14;16), (14;20)) was reported in 42 (17.9%) patients while 1q gain was present in 30 (12.7%) patients. 17p/TP53 del was detected in 7(2.8%) patients. R-ISS was available for 199 patients with 19 (9.5%),134 (67.3%), and 46 (23.1%) having R-ISS I, II and III respectively. **Conclusions:** Our study highlights earlier age of presentation, higher incidence of end organ damage due to myeloma. A low incidence of high risk cytogenetic abnormalities was detected which resulted in a maximum number of patients in R-ISS II category. Though limited by retrospective nature and patient population from a tertiary care institute, the study suggests the need for prospective registry studies to document the potential difference in presentation among Indian patients and need for awareness about myeloma for early diagnosis.

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China; [2]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College

Introduction: Attaining undetectable minimal residual disease (MRD) is the current therapeutic goal for multiple myeloma (MM). But there is a current lack of data regarding the clinical benefit of autologous stem cell transplantation (ASCT) for myeloma patients achieving early MRD-negative status after induction treatment, in addition to the interaction of longitudinal MRD status with ASCT. **Methods:** The present study included 407 transplant-eligible MM patients with available MRD status from the National Longitudinal Cohort of Hematological Diseases in China (NCT04645199), of whom 147 (34.4%) achieved early undetectable MRD and 182 (44.7%) received ASCT. **Results:** Early MRD-negative status was associated with a lower risk of disease progression (HR=0.447; 95%CI, 0.333-0.600; P< 0.001) and death (HR=0.473; 95%CI, 0.320-0.700; P< 0.001). Of note, patients who achieved undetectable MRD early still benefitted from ASCT, with a remarkable improvement in the median MRD-negative duration (33.5 to 58.0 months, P< 0.001), progression-free survival (PFS; 46.0 to 88.3 months, P< 0.001), and overall survival (OS; 76.4 months to not reached, P=0.003). These clinical benefits were more pronounced in patients with aggressive features (high-risk cytogenetic abnormalities or high tumor burden) other than in standard-risk patients. Similar results were observed in patients with detectable MRD after induction treatment. Additionally, we identified four MRD-status transformation patterns following ASCT, which were strongly correlated with diverse survival outcomes (P< 0.001). **Conclusions:** These findings emphasize the crucial role of ASCT in myeloma patients regardless of early MRD status, especially for high-risk patients. Longitudinal MRD conversion after ASCT also has a significant impact on risk stratification.

Introduction: Multiple myeloma is a relapsing remitting type of hematological cancer with no long term cure and heterogeneous outcomes. Presenting features impacts outcomes and varies across different ethnic and geographic regions. Differences with respect to incidence and outcomes in the African American population are well documented. Earlier studies from India have reported young age, late stages of the diseases and high incidence of myeloma defining events. We looked at consecutive cohort of patients with newly diagnosed myeloma over a year at a tertiary cancer institute to see the demographic and presenting characteristics. **Methods:** We did a retrospective analysis of all consecutive newly diagnosed patients with Multiple myeloma between January 2017 and December 2017. Data was collected from the electronic medical record. SPSSV22 was used for descriptive analysis. **Results:** A total of 254 newly diagnosed patients were registered at our hospital in the specified study period. Median age of study population was 57.2 years (range 26 to 79) and 168 (66.1%) were male. Comorbidities were reported in 109(42.9%) patients, mainly hypertension in 66 (60%),diabetes in 43 (39.4%). ECOG performance status was 2 or more in 143 (56.4%) patients. Most common symptom at diagnosis was bone pain, mostly backache, seen in 61.4% patients and 11 (4.4%) patients presented with paraparesis due to cord compression. Bone lesions were detected on imaging in 220 (86.6%), renal involvement in 74 (29.4%), anemia in 142 (55.9%) and hypercalcemia in 42 (16.5%). Fifteen (6%) presented with severe renal failure requiring dialysis. Median Hb was 9.6gm/dl (range 2.8 to 15.8), Median calcium was 9.45mg/dl (range 5.5 to 16.18) and median creatinine was 1.2mg/dl (range 0.6 to 21). The Imaging modality used was skeleton survey in 25.1%, low dose CT in 18.1%, MRI in 38.7% and PET-CT in 18.1%. 62(24.4%) patients had evidence of paramedullary soft tissue plasmacytoma. ISS stage was I in only 44 (17.7%) while ISS-III was present in 115 (46.4%) patients. LDH was elevated in 96 (37.8%) patients. Cytogenetics revealed hyperdiploidy in 98 out of 234 tested for same (38.5%) and high risk IgH translocation (t(4;14), (14;16), (14;20)) was reported in 42 (17.9%) patients while 1q gain was present in 30 (12.7%) patients. 17p/TP53 del was detected in 7(2.8%) patients. R-ISS was available for 199 patients with 19 (9.5%),134 (67.3%), and 46 (23.1%) having R-ISS I, II and III respectively. **Conclusions:** Our study highlights earlier age of presentation, higher incidence of end organ damage due to myeloma. A low incidence of high risk cytogenetic abnormalities was detected which resulted in a maximum number of patients in R-ISS II category. Though limited by retrospective nature and patient population from a tertiary care institute, the study suggests the need for prospective registry studies to document the potential difference in presentation among Indian patients and need for awareness about myeloma for early diagnosis.

Introduction: Because of its relapsing-remitting nature and no long-term cure, patients with multiple myeloma require extended therapy with chemotherapy, novel agents, monoclonal antibodies, and autologous stem cell transplants (ASCT) for optimal outcomes. Attrition during treatment can negatively impact long-term outcomes and factors influencing the same may be important to focus on to achieve optimal patient outcomes. This study aims to examine attrition rates and the factors influencing them. **Methods:** This retrospective study analyzed data from 224 newly diagnosed patients of multiple myeloma from January 2017 to December 2017 at TMH, Mumbai. The patients included had received or were started on at least one line of therapy. The patient factors such as age, co-morbidities, clinical and laboratory evaluations were recorded along with the lines of therapy (LOTs) received, best response, and therapies received including ASCT. Factors predicting attrition were analyzed using a chi-squared test in two groups using SPSS version 22. **Results:** Among the newly diagnosed patients during the study period, the median age was 57 years, with 67.1 % being male. The most common 1st line therapy given was Bortezomib, cyclophosphamide, and dexamethasone combination (76.4% of patients). The attrition rates among the patients were 28.6% for the second LOT, 33.8 % for the 3rd LOT, and 45.3% for the subsequent LOTs. Among the people who dropped out for the second LOT, only 3% of patients had received ASCT, 18.8% of patients had received maintenance post 1st LOT, 2% had associated co-morbidities, 37.5% had renal dysfunction, 46.9% patients were ISS stage III at diagnosis and 28.1% patients had high-risk cytogenetics at presentation. In the group who received second LOT or higher, 11.2% of the patients received ASCT, 27.3 % had received maintenance post 1st LOT, 68.3% had received Radiotherapy, 34.2 % had associated co-morbidities, renal dysfunction was present in 25.5% of the patients, 46% of the patients were ISS stage III at diagnosis and 25.5% patients had high-risk cytogenetics at presentation. Among the factor analyzed, doublet therapy, ECOG scores of 2 or more, and having Del17p at presentation showed a significantly higher likelihood of attrition (p-value of 0.042, 0.011, and 0.014 respectively). The median Overall Survival (OS) was 3.9 years (95% Confidence Interval 3.3 years – 4.6 years). The median Overall Survival (OS) for people who dropped out after first-line of therapy was 1 year (95% Confidence Interval 0.6 years – 1.5 years) compared to an OS of 5.6 years (95% Confidence Interval 5.1 years – 6.0 years) in patients who did receive second-line therapy. **Conclusions:** Our study shows a significant proportion of patients did not receive subsequent lines of therapy in our clinical setting and have inferior survival. Most effective therapies should be used in earlier lines to benefit patients from all available treatment modalities.

Maintenance therapy with carfilzomib, pomalidomide and dexamethasone (KPd) in high-risk myeloma patients (pts): a Phase 2 study with a safety run-in

Ajay Nooka[1], Nisha Joseph[1], Madhav Dhodapkar[1], Craig Hofmeister[1], Vikas Gupta[1], Joel Andrews[1], Charise Gleason[1], Bryan James Burton[1], Manali Rupji[1], Ian McFadden[2], Rani Najdi[2], Lawrence Boise[1], Jonathan Kaufman[1], Sagar Lonial[1]

[1]Winship Cancer Institute, Emory University, Atlanta, GA, USA; [2]Amgen

Introduction: High-risk pts derive survival benefit from combination maintenance (PI and IMiD) strategies. We have evaluated the safety and efficacy of the next generation PI (carfilzomib) and IMiD (pomalidomide) in combination with dexamethasone in high-risk myeloma (NCT03756896) **Methods:** Newly diagnosed high-risk myeloma pts that have achieved ≥PR post-ASCT were included. High-risk myeloma was defined by the presence of t(4;14) in 31%, t(14;16) in 17.2%, del17p in 58.6% pts by FISH or CTG or presence of ≥20% circulating cells (pPCL) in 6.9%. Double-hit myeloma (as defined by presence of ≥2 high-risk cytogenetic abnormalities including gain of 1q) was seen in 58.6% of pts. Each cycle is 28 days. Carfilzomib 20/56 mg/m^2 IV was given on days 1,8,15 and pomalidomide 2 mg PO on days 1 to 21 and dexamethasone 40 mg PO was administered on days of carfilzomib. Statistical analysis was conducted using SAS Version 9.4. **Results:** After the safety run in the first 3 pts, 26 additional pts were enrolled. Median age was 60 years (range, 46–75); 58.6% male and 58.6% black. At diagnosis, 65.5% had RISS stage 3 disease. 54.5% of whites and 64.7% of blacks had double-hit disease. Median time from diagnosis and from transplant to study entry was 9.3 (range, 6.08-12.42) and 2.89 (range, 2-8.51) months, respectively. At study entry, ≥CR and ≥VGPR rates were 24.1% and 68.9%, respectively, which deepened to 89.7% and 100% while on study. The median time to best response was 1.84 months (range, 0-13.34). Of the 15 pts with available MRD data, MRD (10-5) and (10-6) were achieved in 86.7% and 66.7%, respectively. After a median follow-up of 30.5 months, 48 month PFS was 54% and 48 month OS was 67%. Interestingly, all pts that have progressed and/or died had double-hit disease expect 1 patient. There was no PFS or OS difference by RISS. At data cut-off as of May 1st 2023, 27.6% of pts were still receiving treatment; most common reason for permanent

Interestingly, all pts that have progressed and/or died had double-hit disease expect 1 patient. There was no PFS or OS difference by RISS. At data cut-off as of May 1st 2023, 27.6% of pts were still receiving treatment; most common reason for permanent

treatment discontinuation was progressive disease (34.5%). Among the 6 pt deaths, the most common cause of death was progressive disease (83.3%). Most common hematological treatment-emergent adverse events (TEAEs) reported in the cohort included neutropenia [55.2% (Grade 3/4: 55.2%)], anemia [13.8% (Grade 3/4: 0%)] and thrombocytopenia [10.3% (Grade 3/4: 3.4%)]. Non-hematological TEAEs include hypophosphatemia [69% (Grade 3/4: 27.6%)], muscle cramps [38.8% (Grade 3/4: 3.4%)], hypomagnesemia [27.5% (Grade 3/4: 0%)], head ache [24.1% (Grade 3/4: 3.42%)], agitation [20.7% (Grade 3/4: 0%)] and acneiform rash [(20.7% (Grade 3/4: 0%)]. The TEAEs of interest included cardiac [13.8% (Grade 3/4: 3.4%)], cataracts [17.2% (Grade 3/4: 17.2%)] and CVA [3.4% (Grade 3/4: 3.4%)] **Conclusions:** In pts with high-risk myeloma, KPd combination maintenance is safe, well-tolerated and efficacious. Presence of double-hit disease is a predictor for progression. These results support further exploration of combination maintenance strategies among high-risk pts.

Biomarker utility of circRNAs in multiple myeloma: the exemplary cases of ciRS-7 and circCCT3 as surrogate prognostic molecular biomarkers combined with the R-ISS staging system

Maria Papatsirou[1], Ioannis Ntanasis-Stathopoulos[2], Paraskevi Karousi[1], Panagiotis Malandrakis[2], Despina Fotiou[2], Christine-Ivy Liacos[1], Maria Gavriatopoulou[1], Efstathios Kastritis[2], Andreas Scorilas[1], Meletios Dimopoulos[1], Christos Kontos[1], Evangelos Terpos[2]

[1]National and Kapodistrian University of Athens; [2]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece

Introduction: Circular RNAs (circRNAs) are a non-coding RNA type with potential as molecular biomarkers in multiple myeloma (MM). Recently, ciRS-7 was found to be downregulated in MM patients' cells that have acquired resistance to therapy, and circCCT3 has been linked to MM progression. Our goal was to study the expression of these circRNAs in MM, smoldering myeloma (SMM), and monoclonal gammopathy of undetermined significance (MGUS), and to evaluate their clinical significance. **Methods:** 175 patients with plasma cell dyscrasias provided sample. All bone marrow aspirates were immediately processed for CD138+ selection of plasma cells. For the classification of MM patients, the ISS and revised ISS (R-ISS) staging methods were used. L-363, H929, and U266 MM cell lines were also propagated. Total RNA was extracted from the samples and cell lines before reverse transcription and pre-amplification of ciRS-7, circCCT3, and GAPDH (reference gene). Then, utilizing divergent PCR primers, an in-house methodology for the quantification of circRNAs by nested real-time qPCR was developed. The expression of ciRS-7 and circCCT3 was quantified in relative quantification units (RQU). **Results:** The study included 110 newly diagnosed MM patients, 35 with SMM, and 30 with MGUS. The median age of all patients at diagnosis was 70 years; 106 (60.6%) cases were male, while 69 (39.4%) were female. Furthermore, 23 (20.9%) of MM patients were in R-ISS stage I, 62 (56.4%) in R-ISS stage II, and 25 (22.7%) in R-ISS stage III. The intracellular levels of ciRS-7 were significantly different among the 3 patient subgroups (median RQU: 0.40 for MM vs. 1.74 for SMM vs. 2.79for MGUS; P< 0.001), while circCCT3 was upregulated in MM compared to SMM patients (median value: 16.24 RQU in MM vs. 3.07 RQU in SMM; P=0.022). Regarding the survival analysis, ciRS-7 and circCCT3 seem to have opposite effects on the overall (OS) and progression-free survival (PFS) of MM patients. Patients with high levels of ciRS-7 have lower OS (P=0.008) and PFS (P=0.046) probabilities. In contrast, MM patients with high circCCT3 expression had greater OS time intervals (P=0.006); this favorable prognostic significance extends to PFS (P=0.015) as well. Bootstrap multivariate Cox regression analysis showed that the prognostic value of ciRS-7 and circCCT3 expression is independent of R-ISS stage and age of MM patients, both regarding OS (HR=3.69, BCa 95% CI=1.52-14.26, bootstrap P=0.004 for ciRS-7, HR=0.23, BCa 95% CI=0.043-0.57, bootstrap P=0.003 for circCCT3) and PFS (HR=2.01, BCa 95% CI=1.07-3.93, bootstrap P=0.022 for ciRS-7, HR=0.41, BCa 95% CI=0.21-0.74, bootstrap P=0.004 for circCCT3). **Conclusions:** Our study revealed that ciRS-7 and circCCT3 levels differ significantly between patients with MM, SMM, and MGUS. Moreover, both circRNAs have a prognostic value independent of R-ISS staging and age of MM patients; these molecules may be able to serve as additional prognostic biomarkers in MM, integrated with R-ISS.

Comparative analysis of outcomes in patients with CRAB versus SLiM criteria at diagnosis of multiple myeloma

Benjamin Patrick[1], Farid Azadian[2], Hyra S. Sapru[2], Christopher Cipkar[2], Hira Mian[3], Arleigh McCurdy[4], Alissa Visram[2]

[1]Ottawa Hospital Research Institute; [2]The Ottawa Hospital; [3]McMaster University, Hamilton, Ontario, Canada; [4]University of Ottawa

Introduction: In 2014 the International Myeloma Working Group (IMWG) redefined the multiple myeloma (MM) diagnostic criteria to include ultra-high risk smoldering MM patients (those with "SLiM" criteria of bone marrow plasma cell burden (BM PC) >60%, >1 focal lesion on MRI, or a free light chain (FLC) ratio ≥100 with involved FLC >100 mg/L). However, there is a paucity of data to examine the real-world health outcomes of patients initially presenting with end-organ damage ("CRAB": hypercalcemia, anemia, renal failure, or osteolytic bone lesions) versus SLiM criteria. Therefore, this study aimed to compare the progression-free survival (PFS) and overall survival (OS) between patients with only SLiM versus CRAB criteria at MM diagnosis. **Methods:** This retrospective study included patients diagnosed with MM between January 2016 to December 2022 at the Ottawa Hospital. Time to event analyses using the Kaplan-Meier method were used to evaluate the median PFS (primary endpoint) and median OS (secondary endpoint), defined from the time of initiating first line therapy for MM. Overall

treatment discontinuation was progressive disease (34.5%). Among the 6 pt deaths, the most common cause of death was progressive disease (83.3%). Most common hematological treatment-emergent adverse events (TEAEs) reported in the cohort included neutropenia [55.2% (Grade 3/4: 55.2%)], anemia [13.8% (Grade 3/4: 0%)] and thrombocytopenia [10.3% (Grade 3/4: 3.4%)]. Non-hematological TEAEs include hypophosphatemia [69% (Grade 3/4: 27.6%)], muscle cramps [38.8% (Grade 3/4: 3.4%)], hypomagnesemia [27.5% (Grade 3/4: 0%)], head ache [24.1% (Grade 3/4: 3.42%)], agitation [20.7% (Grade 3/4: 0%)] and acneiform rash [(20.7% (Grade 3/4: 0%)]. The TEAEs of interest included cardiac [13.8% (Grade 3/4: 3.4%)], cataracts [17.2% (Grade 3/4: 17.2%)] and CVA [3.4% (Grade 3/4: 3.4%)] **Conclusions:** In pts with high-risk myeloma, KPd combination maintenance is safe, well-tolerated and efficacious. Presence of double-hit disease is a predictor for progression. These results support further exploration of combination maintenance strategies among high-risk pts.

The expression of ciRS-7 and circCCT3 was quantified in relative quantification units (RQU). **Results:** The study included 110 newly diagnosed MM patients, 35 with SMM, and 30 with MGUS. The median age of all patients at diagnosis was 70 years; 106 (60.6%) cases were male, while 69 (39.4%) were female. Furthermore, 23 (20.9%) of MM patients were in R-ISS stage I, 62 (56.4%) in R-ISS stage II, and 25 (22.7%) in R-ISS stage III. The intracellular levels of ciRS-7 were significantly different among the 3 patient subgroups (median RQU: 0.40 for MM vs. 1.74 for SMM vs. 2.79for MGUS; P< 0.001), while circCCT3 was upregulated in MM compared to SMM patients (median value: 16.24 RQU in MM vs. 3.07 RQU in SMM; P=0.022). Regarding the survival analysis, ciRS-7 and circCCT3 seem to have opposite effects on the overall (OS) and progression-free survival (PFS) of MM patients. Patients with high levels of ciRS-7 have lower OS (P=0.008) and PFS (P=0.046) probabilities. In contrast, MM patients with high circCCT3 expression had greater OS time intervals (P=0.006); this favorable prognostic significance extends to PFS (P=0.015) as well. Bootstrap multivariate Cox regression analysis showed that the prognostic value of ciRS-7 and circCCT3 expression is independent of R-ISS stage and age of MM patients, both regarding OS (HR=3.69, BCa 95% CI=1.52-14.26, bootstrap P=0.004 for ciRS-7, HR=0.23, BCa 95% CI=0.043-0.57, bootstrap P=0.003 for circCCT3) and PFS (HR=2.01, BCa 95% CI=1.07-3.93, bootstrap P=0.022 for ciRS-7, HR=0.41, BCa 95% CI=0.21-0.74, bootstrap P=0.004 for circCCT3). **Conclusions:** Our study revealed that ciRS-7 and circCCT3 levels differ significantly between patients with MM, SMM, and MGUS. Moreover, both circRNAs have a prognostic value independent of R-ISS staging and age of MM patients; these molecules may be able to serve as additional prognostic biomarkers in MM, integrated with R-ISS.

Comparative analysis of outcomes in patients with CRAB versus SLiM criteria at diagnosis of multiple myeloma

Benjamin Patrick[1], Farid Azadian[2], Hyra S. Sapru[2], Christopher Cipkar[2], Hira Mian[3], Arleigh McCurdy[4], Alissa Visram[2]

[1]Ottawa Hospital Research Institute; [2]The Ottawa Hospital; [3]McMaster University, Hamilton, Ontario, Canada; [4]University of Ottawa

Introduction: In 2014 the International Myeloma Working Group (IMWG) redefined the multiple myeloma (MM) diagnostic criteria to include ultra-high risk smoldering MM patients (those with "SLiM" criteria of bone marrow plasma cell burden (BM PC) >60%, >1 focal lesion on MRI, or a free light chain (FLC) ratio ≥100 with involved FLC >100 mg/L). However, there is a paucity of data to examine the real-world health outcomes of patients initially presenting with end-organ damage ("CRAB": hypercalcemia, anemia, renal failure, or osteolytic bone lesions) versus SLiM criteria. Therefore, this study aimed to compare the progression-free survival (PFS) and overall survival (OS) between patients with only SLiM versus CRAB criteria at MM diagnosis. **Methods:** This retrospective study included patients diagnosed with MM between January 2016 to December 2022 at the Ottawa Hospital. Time to event analyses using the Kaplan-Meier method were used to evaluate the median PFS (primary endpoint) and median OS (secondary endpoint), defined from the time of initiating first line therapy for MM. Overall

treatment discontinuation was progressive disease (34.5%). Among the 6 pt deaths, the most common cause of death was progressive disease (83.3%). Most common hematological treatment-emergent adverse events (TEAEs) reported in the cohort included neutropenia [55.2% (Grade 3/4: 55.2%)], anemia [13.8% (Grade 3/4: 0%)] and thrombocytopenia [10.3% (Grade 3/4: 3.4%)]. Non-hematological TEAEs include hypophosphatemia [69% (Grade 3/4: 27.6%)], muscle cramps [38.8% (Grade 3/4: 3.4%)], hypomagnesemia [27.5% (Grade 3/4: 0%)], head ache [24.1% (Grade 3/4: 3.42%)], agitation [20.7% (Grade 3/4: 0%)] and acneiform rash [(20.7% (Grade 3/4: 0%)]. The TEAEs of interest included cardiac [13.8% (Grade 3/4: 3.4%)], cataracts [17.2% (Grade 3/4: 17.2%)] and CVA [3.4% (Grade 3/4: 3.4%)] **Conclusions:** In pts with high-risk myeloma, KPd combination maintenance is safe, well-tolerated and efficacious. Presence of double-hit disease is a predictor for progression. These results support further exploration of combination maintenance strategies among high-risk pts.

Introduction: Circular RNAs (circRNAs) are a non-coding RNA type with potential as molecular biomarkers in multiple myeloma (MM). Recently, ciRS-7 was found to be downregulated in MM patients' cells that have acquired resistance to therapy, and circCCT3 has been linked to MM progression. Our goal was to study the expression of these circRNAs in MM, smoldering myeloma (SMM), and monoclonal gammopathy of undetermined significance (MGUS), and to evaluate their clinical significance. **Methods:** 175 patients with plasma cell dyscrasias provided sample. All bone marrow aspirates were immediately processed for CD138+ selection of plasma cells. For the classification of MM patients, the ISS and revised ISS (R-ISS) staging methods were used. L-363, H929, and U266 MM cell lines were also propagated. Total RNA was extracted from the samples and cell lines before reverse transcription and pre-amplification of ciRS-7, circCCT3, and GAPDH (reference gene). Then, utilizing divergent PCR primers, an in-house methodology for the quantification of circRNAs by nested real-time qPCR was developed. The expression of ciRS-7 and circCCT3 was quantified in relative quantification units (RQU). **Results:** The study included 110 newly diagnosed MM patients, 35 with SMM, and 30 with MGUS. The median age of all patients at diagnosis was 70 years; 106 (60.6%) cases were male, while 69 (39.4%) were female. Furthermore, 23 (20.9%) of MM patients were in R-ISS stage I, 62 (56.4%) in R-ISS stage II, and 25 (22.7%) in R-ISS stage III. The intracellular levels of ciRS-7 were significantly different among the 3 patient subgroups (median RQU: 0.40 for MM vs. 1.74 for SMM vs. 2.79for MGUS; P< 0.001), while circCCT3 was upregulated in MM compared to SMM patients (median value: 16.24 RQU in MM vs. 3.07 RQU in SMM; P=0.022). Regarding the survival analysis, ciRS-7 and circCCT3 seem to have opposite effects on the overall (OS) and progression-free survival (PFS) of MM patients. Patients with high levels of ciRS-7 have lower OS (P=0.008) and PFS (P=0.046) probabilities. In contrast, MM patients with high circCCT3 expression had greater OS time intervals (P=0.006); this favorable prognostic significance extends to PFS (P=0.015) as well. Bootstrap multivariate Cox regression analysis showed that the prognostic value of ciRS-7 and circCCT3 expression is independent of R-ISS stage and age of MM patients, both regarding OS (HR=3.69, BCa 95% CI=1.52-14.26, bootstrap P=0.004 for ciRS-7, HR=0.23, BCa 95% CI=0.043-0.57, bootstrap P=0.003 for circCCT3) and PFS (HR=2.01, BCa 95% CI=1.07-3.93, bootstrap P=0.022 for ciRS-7, HR=0.41, BCa 95% CI=0.21-0.74, bootstrap P=0.004 for circCCT3). **Conclusions:** Our study revealed that ciRS-7 and circCCT3 levels differ significantly between patients with MM, SMM, and MGUS. Moreover, both circRNAs have a prognostic value independent of R-ISS staging and age of MM patients; these molecules may be able to serve as additional prognostic biomarkers in MM, integrated with R-ISS.

Introduction: In 2014 the International Myeloma Working Group (IMWG) redefined the multiple myeloma (MM) diagnostic criteria to include ultra-high risk smoldering MM patients (those with "SLiM" criteria of bone marrow plasma cell burden (BM PC) >60%, >1 focal lesion on MRI, or a free light chain (FLC) ratio ≥100 with involved FLC >100 mg/L). However, there is a paucity of data to examine the real-world health outcomes of patients initially presenting with end-organ damage ("CRAB": hypercalcemia, anemia, renal failure, or osteolytic bone lesions) versus SLiM criteria. Therefore, this study aimed to compare the progression-free survival (PFS) and overall survival (OS) between patients with only SLiM versus CRAB criteria at MM diagnosis. **Methods:** This retrospective study included patients diagnosed with MM between January 2016 to December 2022 at the Ottawa Hospital. Time to event analyses using the Kaplan-Meier method were used to evaluate the median PFS (primary endpoint) and median OS (secondary endpoint), defined from the time of initiating first line therapy for MM. Overall

response rate (ORR) was defined as achieving a partial response or better. Nonparametric methods were used to compare baseline demographic and treatment characteristics of SLiM versus CRAB patients. **Results:** Overall, 617 MM patients were included in the study (49 [8%] with SLiM MM and 567 [92%] with CRAB MM). Among patients with CRAB MM, the most common presentation was osteolytic lesions (n=340, 60%), anemia (n=269, 47%), renal failure (n=118, 21%), then hypercalcemia (n=63, 11%), as defined by the IMWG (Rajkumar et al. Lancet Oncol. 2014). Among SLiM MM patients, the most common treatment indications were BM PC >60% (n=21, 42.9%), FLC ratio ≥100 (n=13, 26.5%), followed by focal lesions on MRI (n=13, 26.5%). SLiM versus CRAB MM patients had similar ages at diagnosis (median age 67.3 versus 67.5 years, respectively, p=0.889) and similar proportions of patients with ISS stage 3 disease at diagnosis (33% versus 26.5%, respectively, p=0.076). Treatment of SLiM versus CRAB patients was similar; immunomodulatory drugs or proteosome inhibitors were used in first line treatment in 90% versus 92% of patients (p=0.578), and 49% versus 44% of patients received an upfront transplant (p=0.553). SLiM versus CRAB MM patients had a similar PFS (median PFS 36.9 versus 31.8 months, respectively, p=0.365) and ORR (89% in both groups, p=0.964). However, there was a trend towards longer OS among patients presenting with SLiM versus CRAB MM (median PFS 99.5 versus 66.7 months, respectively, p=0.070). **Conclusions:** Despite similar baseline demographics and treatments, we found a trend towards improved survival among patients treated for SLiM MM. Further work is needed to identify whether survival benefits are due to persistence of less resistant clones leading to longer PFS at relapse. However, these real-world data support the current practice of early intervention in patients with SLiM MM.

Outcomes of a bortezomib-based induction regimen (sequential or upfront triple association with lenalidomide) in transplant-eligible patients withh newly diagnosed multiple myeloma

Isabel Paulos-Mesquita[1], Joana Vieira[1], Eduardo Espada[1], Pedro Martins-Almeida[1], Margarida Duarte[1], Catarina Lopes-Silva[1], Helena Martins[1], João Raposo[1], Graça Esteves[1]

[1]Centro Hospitalar de Lisboa Norte, EPE - Hospital Santa Maria

Introduction: The association of lenalidomide to bortezomib and dexamethasone (VRd) as induction therapy (IT) in newly diagnosed multiple myeloma (NDMM) patients (pts) eligible for autologous stem-cell transplantation (ASCT) has demonstrated excellent response rates and survival outcomes with manageable toxicities. Urgent treatment is often required in this setting and lenalidomide may not be immediately available for upfront use. **Methods:** Single center retrospective study, including NDMM pts treated between Jan/2018-Jun/2022, who received IT with VRd, using a sequential regimen (sVRd) (bi-weekly Vd for 1-2 cycles followed by association of lenalidomide in the remaining cycles) or a 28-day VRd regimen upfront (uVRd), for 6 cycles. This study aims to evaluate clinical characteristics, efficacy, toxicities and survival outcomes with VRd and to compare the sVRd versus uVRd. High risk cytogenetic abnormalities (HRCAs) defined by the Revised-International Staging System (R-ISS): del17p, t(4;14) and/or t(14;16). CRAB criteria and response evaluation according to the IMWG criteria. Toxicities graded according to CTCAE v5.0. **Results:** 62 pts; median age of 62.5 years (range 42-70); 53.2% male. Clinical characteristics at diagnosis: 80.6% lytic bone lesions, 43.5% anemia, 25.8% kidney failure and 9.7% hypercalcemia. 10% had HRCAs and 38% amp1q21 (FISH available in 79%). ISS stage III present in 37.3% and R-ISS stage III in 10.6%. All pts were treated with VRd (median 8 cycles), of which 66.1% (n=41) received sVRd (group 1) and 32.3% (n=20) received uVRd (group 2). 58.1% underwent single ASCT, 3.2% tandem ASCT and 9.7% salvage-ASCT (after ≥2nd line therapy). 77.3% of ASCT pts received maintenance therapy (76.5% including lenalidomide). 69.4% experienced grade ≥2 treatment-related toxicities: 32.3% peripheral neuropathy, 30.6% infection, 17.7% hematologic toxicity, 9.7% lenalidomide-related rash and 4.8% thrombotic events. Overall response rate at the end of IT was 85.5% (complete response 40.3%; very good partial response 30.6%; partial response [PR] 14.5%), with no differences between groups. 14.5% of the pts had treatment failure (< PR). At median follow-up (MFU) of 22.0 months (mo), progression-free survival (PFS) was 77.7% and overall survival (OS) 85.4%. Median PFS was 52.8 mo (95% CI 33.55-71.98) and median OS was not reached. There were no differences between groups in PFS (at MFU: gr1 82.7% vs. gr2 75%; p=0.783) or OS (at MFU: gr1 87.3% vs. gr2 89.7%; p=0.736). **Conclusions:** The use of VRd as 1st line therapy has shown great efficacy in this real-word population, with outcomes consistent with recent published data. Our results also prove non-inferiority of a sequential strategy versus the use of a triplet-regimen upfront. This treatment approach may benefit pts requiring urgent treatment (e.g. kidney failure) or with poor performance-status at diagnosis. Furthermore, it can be useful to test disease sensitivity to different treatment classes.

How public policies have improved the overall survival of transplant eligible newly diagnosed multiple myeloma patients in the Chilean public health system

Patricia Graffigna[1], Moises Russo[2], Claudia Gajardo[3], Daniela Zambrano[3], Verónica Lizama[3], Macarena Roa[3], Karen Lopez[3], Gabriela Espinoza[3], Ximena Valladares[3], Camila Peña[3]

[1]Hospital del Salvador; [2]Fundación Arturo Lopez Perez; [3]Hospital del Salvador, Santiago de Chile

Introduction: In Chile, particularly in the public system, treatment of patients with transplant eligible NDMM has evolved, being divided into 4 treatment periods endorsed and financed by the Ministry of Health, since 2000. The main aim of this study was to evaluate the overall survival (OS) of these patients in the different periods. **Methods:** Ambispective observational cohort study. A total of 213 ≤65 years patients from our institutional registry were analyzed.

response rate (ORR) was defined as achieving a partial response or better. Nonparametric methods were used to compare baseline demographic and treatment characteristics of SLiM versus CRAB patients. **Results:** Overall, 617 MM patients were included in the study (49 [8%] with SLiM MM and 567 [92%] with CRAB MM). Among patients with CRAB MM, the most common presentation was osteolytic lesions (n=340, 60%), anemia (n=269, 47%), renal failure (n=118, 21%), then hypercalcemia (n=63, 11%), as defined by the IMWG (Rajkumar et al.
