response rate (ORR) was defined as achieving a partial response or better. Nonparametric methods were used to compare baseline demographic and treatment characteristics of SLiM versus CRAB patients. **Results:** Overall, 617 MM patients were included in the study (49 [8%] with SLiM MM and 567 [92%] with CRAB MM). Among patients with CRAB MM, the most common presentation was osteolytic lesions (n=340, 60%), anemia (n=269, 47%), renal failure (n=118, 21%), then hypercalcemia (n=63, 11%), as defined by the IMWG (Rajkumar et al. Lancet Oncol. 2014). Among SLiM MM patients, the most common treatment indications were BM PC >60% (n=21, 42.9%), FLC ratio ≥100 (n=13, 26.5%), followed by focal lesions on MRI (n=13, 26.5%). SLiM versus CRAB MM patients had similar ages at diagnosis (median age 67.3 versus 67.5 years, respectively, p=0.889) and similar proportions of patients with ISS stage 3 disease at diagnosis (33% versus 26.5%, respectively, p=0.076). Treatment of SLiM versus CRAB patients was similar; immunomodulatory drugs or proteosome inhibitors were used in first line treatment in 90% versus 92% of patients (p=0.578), and 49% versus 44% of patients received an upfront transplant (p=0.553). SLiM versus CRAB MM patients had a similar PFS (median PFS 36.9 versus 31.8 months, respectively, p=0.365) and ORR (89% in both groups, p=0.964). However, there was a trend towards longer OS among patients presenting with SLiM versus CRAB MM (median PFS 99.5 versus 66.7 months, respectively, p=0.070). **Conclusions:** Despite similar baseline demographics and treatments, we found a trend towards improved survival among patients treated for SLiM MM. Further work is needed to identify whether survival benefits are due to persistence of less resistant clones leading to longer PFS at relapse. However, these real-world data support the current practice of early intervention in patients with SLiM MM.

Outcomes of a bortezomib-based induction regimen (sequential or upfront triple association with lenalidomide) in transplant-eligible patients withh newly diagnosed multiple myeloma

Isabel Paulos-Mesquita[1], Joana Vieira[1], Eduardo Espada[1], Pedro Martins-Almeida[1], Margarida Duarte[1], Catarina Lopes-Silva[1], Helena Martins[1], João Raposo[1], Graça Esteves[1]

[1]Centro Hospitalar de Lisboa Norte, EPE - Hospital Santa Maria

Introduction: The association of lenalidomide to bortezomib and dexamethasone (VRd) as induction therapy (IT) in newly diagnosed multiple myeloma (NDMM) patients (pts) eligible for autologous stem-cell transplantation (ASCT) has demonstrated excellent response rates and survival outcomes with manageable toxicities. Urgent treatment is often required in this setting and lenalidomide may not be immediately available for upfront use. **Methods:** Single center retrospective study, including NDMM pts treated between Jan/2018-Jun/2022, who received IT with VRd, using a sequential regimen (sVRd) (bi-weekly Vd for 1-2 cycles followed by association of lenalidomide in the remaining cycles) or a 28-day VRd regimen upfront (uVRd), for 6 cycles. This study aims to evaluate clinical characteristics, efficacy, toxicities and survival outcomes with VRd and to compare the sVRd versus uVRd. High risk cytogenetic abnormalities (HRCAs) defined by the Revised-International Staging System (R-ISS): del17p, t(4;14) and/or t(14;16). CRAB criteria and response evaluation according to the IMWG criteria. Toxicities graded according to CTCAE v5.0. **Results:** 62 pts; median age of 62.5 years (range 42-70); 53.2% male. Clinical characteristics at diagnosis: 80.6% lytic bone lesions, 43.5% anemia, 25.8% kidney failure and 9.7% hypercalcemia. 10% had HRCAs and 38% amp1q21 (FISH available in 79%). ISS stage III present in 37.3% and R-ISS stage III in 10.6%. All pts were treated with VRd (median 8 cycles), of which 66.1% (n=41) received sVRd (group 1) and 32.3% (n=20) received uVRd (group 2). 58.1% underwent single ASCT, 3.2% tandem ASCT and 9.7% salvage-ASCT (after ≥2nd line therapy). 77.3% of ASCT pts received maintenance therapy (76.5% including lenalidomide). 69.4% experienced grade ≥2 treatment-related toxicities: 32.3% peripheral neuropathy, 30.6% infection, 17.7% hematologic toxicity, 9.7% lenalidomide-related rash and 4.8% thrombotic events. Overall response rate at the end of IT was 85.5% (complete response 40.3%; very good partial response 30.6%; partial response [PR] 14.5%), with no differences between groups. 14.5% of the pts had treatment failure (< PR). At median follow-up (MFU) of 22.0 months (mo), progression-free survival (PFS) was 77.7% and overall survival (OS) 85.4%. Median PFS was 52.8 mo (95% CI 33.55-71.98) and median OS was not reached. There were no differences between groups in PFS (at MFU: gr1 82.7% vs. gr2 75%; p=0.783) or OS (at MFU: gr1 87.3% vs. gr2 89.7%; p=0.736). **Conclusions:** The use of VRd as 1st line therapy has shown great efficacy in this real-word population, with outcomes consistent with recent published data. Our results also prove non-inferiority of a sequential strategy versus the use of a triplet-regimen upfront. This treatment approach may benefit pts requiring urgent treatment (e.g. kidney failure) or with poor performance-status at diagnosis. Furthermore, it can be useful to test disease sensitivity to different treatment classes.

How public policies have improved the overall survival of transplant eligible newly diagnosed multiple myeloma patients in the Chilean public health system

Patricia Graffigna[1], Moises Russo[2], Claudia Gajardo[3], Daniela Zambrano[3], Verónica Lizama[3], Macarena Roa[3], Karen Lopez[3], Gabriela Espinoza[3], Ximena Valladares[3], Camila Peña[3]

[1]Hospital del Salvador; [2]Fundación Arturo Lopez Perez; [3]Hospital del Salvador, Santiago de Chile

Introduction: In Chile, particularly in the public system, treatment of patients with transplant eligible NDMM has evolved, being divided into 4 treatment periods endorsed and financed by the Ministry of Health, since 2000. The main aim of this study was to evaluate the overall survival (OS) of these patients in the different periods. **Methods:** Ambispective observational cohort study. A total of 213 ≤65 years patients from our institutional registry were analyzed.

Since 2013 the registry is prospective. Four periods were defined: 1 (P1) from 2000 to 2007, in which there was only melphalan-prednisone as treatment; Period 2 (P2) from 2008 to 2013, in which thalidomide began to be used for some young patients, in addition to autologous stem cell transplantation (ASCT) in some cases; Period 3 (P3) from 2014 to 2018, in which the protocol to be used was cyclophosphamide-thalidomide-dexamethasone (CTD) and ASCT; Period 4 (P4) from 2019 to 2022, in which triplets based on bortezomib, ASCT and post-transplant maintenance with lenalidomide were used. The indications for ASCT in all periods were restrictive: Only for patients ≤60 years in very good partial response (VGPR) or better. Treatment in the different periods, early mortality (defined as death within the first 6 months of diagnosis), and OS of each group were analyzed. **Results:** There were 37 patients at P1, 56 at P2, 61 at P3, and 59 at P4. At P1, 65% of patients were treated with a melphalan-prednisone regimen, 8% VAD, and 8% with a thalidomide-based regimen. No ASCT was performed, and early mortality rate was 24%. At P2, 71% were treated with a thalidomide-based regimen (13% CTD, 87% Thaldex), 20% based on melphalan, and 2% based on bortezomib. 21% had ASCT performed and 9% received maintenance (Thalidomide-based). Early mortality was 16%. At P3, 90% received a thalidomide-based regimen (82% CTD) and 10% based on bortezomib. 33% underwent ASCT, 20% received maintenance (100% thalidomide-based) and early mortality was 16%. At P4, 97% were treated with bortezomib-based triplets. 36% were transplanted. Maintenance was administered to 75% of patients, 93% based on lenalidomide. Early mortality was 7%. With a median follow-up of 77.5 months, the median OS for the entire group was 55.1 months. The median OS of P4, P3, P2 and P1 was Not reached, 96, 35 and 25 months, respectively (p< 0.0001). **Conclusions:** OS has increased in each treatment period. Induction regimens have gone from being melphalan-based, then thalidomide-based, to finally being mostly bortezomib-based. Transplant and maintenance rates have increased over time. Early mortality has decreased, especially in the last period. The median OS of P3 is 8 years, better than expected, as the induction and maintenance regimen was mainly thalidomide-based. P4 showed a trend of an even better OS. Longer follow up is needed. In conclusion, public policies in the Chilean public system have managed to increase OS in our patients.

Experience at Son Espases University Hospital with daratumumab, bortezomib, lenalidomide and dexamethasone (D-VRd) as first line treatment in multiple myeloma

Lola Piquer Monsonis[1], Maria Galí Sampalo[1], Albert Perez Montaña[1], Jose Maria Sánchez Raga[1], Antonia Sampol Mayol[1]

[1]Hospital Universitari Son Espases

Introduction: Multiple myeloma (MM) is characterized by uncontrolled plasma cell proliferation, anaemia, renal failure, hypercalcemia, osteolytic bone lesions, and immunodeficiency. First line treatment in patients who are candidates for autologous stem cell transplantation (ASCT) is based on triplets, basically the combination of bortezomib, lenalidomide and dexamethasone (VRd) during 4-6 cycles. The latest studies add a 4th drug to current triplets, a monoclonal antibody against CD38 which seems to improve treatment responses without increasing toxicity. The main aim of our research is to show our experience on a third level hospital with a quadruple induction regimen (D-VRd) as first line treatment in MM. **Methods:** A retrospective descriptive study was carried out analyzing 11 patients diagnosed with MM and treated in first line with D-VRd from February 2022 until April 2023 at Hospital Universitari Son Espases. We analyzed clinical-biological parameters, prognostic staging systems, treatment, and clinical outcomes. **Results:** We analyzed 11 patients, 6 of whom were male (55%). Median age was 57 years old (range 41-69). Six patients had performance status ECOG 0 and 5 patients ECOG 1 at diagnosis. Based on the International Staging System (ISS): 7 patients (64%) were stage I, 2 (18%) stage II and 2 (18%) stage III. On the other hand, when analyzing R-ISS: 4 patients (36%) were stage I, 2 (18%) stage II, 2 patients (18%) stage III and lastly 3 (27%) were not classified due to lack of FISH results. Regarding stratification risk based on FISH (R-ISS criteria): 2 patients were high risk; 6 were standard-risk and 3 unknown due to lack of FISH. Average filtration rate at the beginning of treatment was 84 ml/min/1,73 m^2 (range 21-104). All patients were planned to receive 6 cycles of 28 days (bortezomib 1.3 mg/m^2 on days 1,4,8,11; lenalidomide 25 mg for 21 days; dexamethasone 40 mg on days 1-4, 9-12). Five out of eleven had finished treatment; the remaining 6 patients are either on the process of collecting stem cells or on the completion of their induction therapy. Overall response rate (ORR) was 100%. Two patients (18%) achieved complete response (CR), 5 (45%) very good partial response (VGPR) and 4 (37%) partial response (PR). Seven patients achieved its first response after the first cycle. With a median follow up of 7 months, progression free survival rate was 100%. Regarding side effects, 2 patients (18%) suffered serious adverse events (SAE): one patient had a pulmonary thromboembolism, so treatment was resumed without lenalidomide and the other patient suffered two serious pulmonary infections. Other common adverse effects were asthenia, polyneuropathy and neutropenia. **Conclusions:** In general, D-VRd treatment was well tolerated, with excellent results attending to the 100% ORR with 55% of VGPR or better in our cohort. Respiratory infections were the main serious adverse event in our experience. Results from the phase 3 trial may clarify the usefulness of this combination in a near future.

Introduction: Lenalidomide (Len) maintenance remains the cornerstone of multiple myeloma (MM) treatment in patients after upfront autologous stem cell transplantation. Yet the data about the benefit of Len monotherapy in high-risk patients remains questioned. Here we aimed on describing the benefit of Len maintenance in subgroups of patients defined by the novel R2-ISS risk stratification system. **Methods:** This was a retrospective analysis from the Czech Myeloma Group Registry of Monoclonal gammopathies (RMG). Patients with MM (followed from May 2007 until March 2023) who underwent induction therapy of at least triplet containing steroid and at least one IMID and/or PI and autologous stem cell transplantation with available baseline cytogenetic results, LDH and ISS stage were included in the analysis. Patients were stratified according to R2-ISS (D´Agostino, JCO JCO2102614.2022) and separated into two groups: no maintenance and Len maintenance. Treatment intervals (PFS, OS, TTP, TNT, DOR) were calculated and survival analysis was performed. **Results:** Overall, 927 patients were identified and suitable for final analysis. Out of these, 180 patients (19.4%) received Len maintenance whereas the others did not (no available maintenance at that time). The median age in the Len group was 62.5 years (43.8-69.6) versus 60.3 years (43.9-69.6) in the no maintenance group (p=0.014). 175/927 (18.9%) were R2-ISS-I (37/175, 21.1% in Len group), 252/927 (27.2%) were R2-ISS-II (45/252, 17.9% in Len group), 378/927 (40.1%) were R2-ISS-III (74/378, 19.6% in Len group) and 122/927 (13.2%) patients were R2-ISS-IV (24/122, 19.7% in Len group). All R2-ISS groups showed progression-free survival (PFS) benefits from MM diagnosis when Len maintenance was used. R2-ISS-I low-risk group 71.0 months (m) (95% CI 71.0-NA) versus 39.7 m (95% CI 35.0-47.2, p=0.027). R2-ISS-II intermediate-low group 54.0 months (95% CI 39.7-NA) versus 32.7 months (95% CI 30.1-36.7, p=0.001). R2-ISS-III intermediate-high group 45.7 m (95% CI 41.2-NA) versus 28.9 m (95% CI 26.4-33.3, p=0.001). R2-ISS-IV high group 34.5 m (95% CI 22.9-NA) versus 23.2 m (95% CI 20.1-29.8, p=0.168). Overall survival was not significantly different in either group. **Conclusions:** The benefit of Len maintenance was seen across all R2-ISS groups of patients confirming the importance of this therapy in all patients regardless of their risk stratification. The lowest benefit was seen in the R2-ISS-IV group (likely due to the small number of patients receiving Len maintenance in this group). In our cohort, Len maintenance significantly improved PFS across stages I-III did not completely overcome the negative impact of stage IV.

Introduction: Multiple Myeloma (MM) is a heterogeneous disease with a genetic profile playing a major role in prognosis and treatment outcome. The high risk genetic abnormalities defined by mSMART 3.0 are t(4;14), t(14;16), t(14;20), del 17p, p53 mutation and gain 1q. Ultra High-Risk Myeloma includes double-hit MM (coexistence of two high-risk abnormalities) and triple-hit MM (coexistence of three high-risk abnormalities). Ultra High-Risk subset is associated with poor prognosis and real-world data on management are limited. **Methods:** The hospital OPD registry of newly diagnosed Multiple Myeloma patients registered between January 2016 and December 2019 was searched to find 48 patients with ultra-high-risk Myeloma. We retrospectively analyzed the demographics, management, and outcome of ultra-high-risk patients. SPSS descriptive statistics were performed for demographic characteristics. Kaplan-Meier plots were used for survival analysis. Univariate analysis was done to see the impact of baseline characteristics on progression-free survival (PFS) and overall survival (OS). **Results:** The median age of the population was 54.5 years (range 28 years – 72 years). Thirty-one patients (64.6%) were Male. ECOG PS was 0-2 in 35 patients (72.9%). Thirty-two patients (66.7%) had ISS III and R-ISS III disease. 23 (47.9%) received Proteosome Inhibitor (PI)-based triplet (VCD/VMP) and 22 (45.8%) received PI+Immunomodulatory agents (IMiD) based triplet (VRD/VTD/VPD) as initial therapy.

Introduction: Lenalidomide (Len) maintenance remains the cornerstone of multiple myeloma (MM) treatment in patients after upfront autologous stem cell transplantation. Yet the data about the benefit of Len monotherapy in high-risk patients remains questioned. Here we aimed on describing the benefit of Len maintenance in subgroups of patients defined by the novel R2-ISS risk stratification system. **Methods:** This was a retrospective analysis from the Czech Myeloma Group Registry of Monoclonal gammopathies (RMG). Patients with MM (followed from May 2007 until March 2023) who underwent induction therapy of at least triplet containing steroid and at least one IMID and/or PI and autologous stem cell transplantation with available baseline cytogenetic results, LDH and ISS stage were included in the analysis. Patients were stratified according to R2-ISS (D´Agostino, JCO JCO2102614.2022) and separated into two groups: no maintenance and Len maintenance. Treatment intervals (PFS, OS, TTP, TNT, DOR) were calculated and survival analysis was performed. **Results:** Overall, 927 patients were identified and suitable for final analysis. Out of these, 180 patients (19.4%) received Len maintenance whereas the others did not (no available maintenance at that time). The median age in the Len group was 62.5 years (43.8-69.6) versus 60.3 years (43.9-69.6) in the no maintenance group (p=0.014). 175/927 (18.9%) were R2-ISS-I (37/175, 21.1% in Len group), 252/927 (27.2%) were R2-ISS-II (45/252, 17.9% in Len group), 378/927 (40.1%) were R2-ISS-III (74/378, 19.6% in Len group) and 122/927 (13.2%) patients were R2-ISS-IV (24/122, 19.7% in Len group). All R2-ISS groups showed progression-free survival (PFS) benefits from MM diagnosis when Len maintenance was used. R2-ISS-I low-risk group 71.0 months (m) (95% CI 71.0-NA) versus 39.7 m (95% CI 35.0-47.2, p=0.027). R2-ISS-II intermediate-low group 54.0 months (95% CI 39.7-NA) versus 32.7 months (95% CI 30.1-36.7, p=0.001). R2-ISS-III intermediate-high group 45.7 m (95% CI 41.2-NA) versus 28.9 m (95% CI 26.4-33.3, p=0.001). R2-ISS-IV high group 34.5 m (95% CI 22.9-NA) versus 23.2 m (95% CI 20.1-29.8, p=0.168). Overall survival was not significantly different in either group. **Conclusions:** The benefit of Len maintenance was seen across all R2-ISS groups of patients confirming the importance of this therapy in all patients regardless of their risk stratification. The lowest benefit was seen in the R2-ISS-IV group (likely due to the small number of patients receiving Len maintenance in this group). In our cohort, Len maintenance significantly improved PFS across stages I-III did not completely overcome the negative impact of stage IV.

Introduction: Multiple Myeloma (MM) is a heterogeneous disease with a genetic profile playing a major role in prognosis and treatment outcome. The high risk genetic abnormalities defined by mSMART 3.0 are t(4;14), t(14;16), t(14;20), del 17p, p53 mutation and gain 1q. Ultra High-Risk Myeloma includes double-hit MM (coexistence of two high-risk abnormalities) and triple-hit MM (coexistence of three high-risk abnormalities). Ultra High-Risk subset is associated with poor prognosis and real-world data on management are limited. **Methods:** The hospital OPD registry of newly diagnosed Multiple Myeloma patients registered between January 2016 and December 2019 was searched to find 48 patients with ultra-high-risk Myeloma. We retrospectively analyzed the demographics, management, and outcome of ultra-high-risk patients. SPSS descriptive statistics were performed for demographic characteristics. Kaplan-Meier plots were used for survival analysis. Univariate analysis was done to see the impact of baseline characteristics on progression-free survival (PFS) and overall survival (OS). **Results:** The median age of the population was 54.5 years (range 28 years – 72 years). Thirty-one patients (64.6%) were Male. ECOG PS was 0-2 in 35 patients (72.9%). Thirty-two patients (66.7%) had ISS III and R-ISS III disease. 23 (47.9%) received Proteosome Inhibitor (PI)-based triplet (VCD/VMP) and 22 (45.8%) received PI+Immunomodulatory agents (IMiD) based triplet (VRD/VTD/VPD) as initial therapy.

The median PFS was 20 months (95% CI: 0 – 42.63), the median second progression free survival (PFS2) was 1 month (95% CI not calculable) and the median OS was 25 months (95% CI: 9.48 – 40.52). On univariate analysis, PFS and OS were not associated with baseline co-morbidities, ECOG PS, ISS, R-ISS, or the presence of plasma cells in peripheral blood. The presence or absence of del 17p or p53 mutation also did not affect survival outcomes. Similarly, the presence of double-hit versus triple-hit did not affect the PFS or OS of the patients and autologous hematopoietic stem cell transplant (auto-HSCT) was not associated with significantly improved PFS and OS in our analysis. Only 5 patients underwent auto-HSCT post-induction chemotherapy. Patients who received maintenance had a significantly better median PFS (44 months vs 8 months) and median OS (68 months vs 9 months). The magnitude of benefit from different maintenance strategies cannot be ascertained due to the small number. **Conclusions:** Our analysis gives us a real-world experience of the ultra-high-risk subgroup and adverse outcomes similar to other studies reported in this group of patients. Our study did show improved outcomes with maintenance in this subgroup of patients. Large-scale prospective data is required to understand the outcomes and best management strategies for this adverse risk group of Multiple Myeloma patients.

Impact of induction treatment on the survival of patients with multiple myeloma candidates for autologous stem cell transplantation: experience of a center

Raquel Santoja[1], Eugenia Rivero[1], Izarbe Delgado[1], Yasmina Seres[1], Armando Luaña[1], Ainara Ferrero[1], Montserrat Teixidó[1], Carlos Chavez[1], Ana Pimentel[1], Albert Tugues[1], Cristina Marzo[1], Eva Vicente[1], Maria Tehas[1], Tomas Garcia-Cerecedo[1], Antonio Garcia-Guiñon[1]

[1]Hospital Universitari Arnau de Vilanova, Lleida

Introduction: Actually, despite the incorporation of new treatments in multiple myeloma, autologous hematopoietic stem cell transplantation (ASCT) continues to be the frontline treatment for those patients who are candidates to intensive treatment. **Methods:** A retrospective analysis was performed in multiple myeloma patients who received ASCT from 1995 to 2020. The objective of our study was to analyze the evolution of progression-free survival (PFS) and overall survival (OS) in patients with multiple myeloma undergoing ASCT at our center. We have analyzed the results based on the type of induction received according to current clinical practice: chemotherapy (CT), Bortezomib-Dexamethasone (VD) or triplet therapy with Bortezomib, Thalidomide and Dexamethasone (VTD). We analyzed the impact of maintenance treatment with Lenalidomide in patients who have received VTD therapy. Inductions treatments were performed in different periods of time: QT (1995-2011), VD (2011-2014) and VTD (2015-2020). **Results:** Eighty patients have been included, 52 (65%) of them were male. The median age at diagnosis was 58 (34-70) years and at ASCT was 59 (39-71) years. The induction treatment received in 33 (41%) patients was CT based on VBMCP/VBAD regimen, 13 (16%) patients with VD and 34 (43%) patients with VTD. Twenty-three (29%) patients with VTD schedule received maintenance therapy with lenalidomide. Median PFS was 20.2 (95%CI, 14.6-25.8) months in patients who received CT and 16.8 (95%CI, 11.1-22.3) months for VD. Median PFS has not been reached in patients who received VTD (figure 1). PFS analysis showed statistically significant differences between VTD and QT ($p< 0.001$) and VD ($p< 0.001$). No significant differences was observed between QT and VD groups ($p=0.2$). Patients who received maintenance show a higher PFS than those who did not, despite difference is not statistically significant ($p=0.19$). Median overall survival (OS) was similar in patients who received CT and VD: 72.7 (95% CI, 64.3-81.2) months and 90.6 (46.6-134.4) months, respectively. Median OS was not reached in patients who received VTD. The OS analysis showed statistically significant difference between VTD and QT ($p< 0.001$) and VD ($p=0.002$). No differences were observed in overall survival ($p=0.8$) in patients who received maintenance with lenalidomide (figure 2). **Conclusions:** Survival analysis (PFS and OS) of patients in our center who received ASCT shows that the addition of Bortezomib combined with Dexamethasone did not provide a benefit compared to polychemotherapy. On the other hand, the incorporation of the triplet therapy with Bortezomib, Thalidomide and Dexamethasone (VTD) has improved the survival (PFS and OS) than CT and VD regimens. According to the impact of maintenance post-transplantation with lenalidomide, a trend to benefit was observed in PFS, although no differences were observed in OS. This lack of benefit may be due to the short follow-up of the series, so it should be analyzed later with a longer follow-up.

Introduction: High dose melphalan with autologous hematopoietic stem cell transplantation (AHCT) for multiple myeloma is effective for disease control, but has a period of obligate neutropenia. With a mechanism of action distinct to G-CSF, plinabulin, a selective immunomodulating microtubule-binding agent, prevents chemotherapy-induced neutropenia (CIN) and

may have anti-tumor activity in solid tumors. In this pilot study (NCT05130827), plinabulin was incorporated with the intent to shorten the duration of neutropenia after AHCT, thereby limiting the toxicities at count nadir. **Methods:** On Day 0, 40mg of intravenous plinabulin was given 1-3 hours after stem cell infusion with pegfilgrastim on Day +1. Plinabulin pharmacokinetic profiling (end of infusion, 30min, 4hr, 24hr, and 48hr), toxicities of the combination, engraftment, disease response, progression free and overall survival, and patient reported outcome (PRO) assessment of symptom burden were secondary endpoints. Eleven concurrent standard-of-care (SOC) patients had similar assessments for comparison. **Results:** Between January 2022 and February 2023, 15 patients (median age 64 (range 54-74), 67% female, 73% melphalan 200mg/m^2) received plinabulin. Median CD34+ cells/kg infused was 4.12 x 10^6 (range 2.18 – 7.85). Half the patients had hypertension (HTN) immediately after the plinabulin infusion, which is a known toxicity and resolved within a few hours. Median plinabulin serum AUC was 1249.5mg*h/L (range 192.6 -5092.5). Median WBC on Day 0, 1, and 2 was 7.67 (3.6 – 11.5), 5.2 (3.2 – 13.6), and 17.1 (5.1-59.1), respectively. Median time to ANC >0.5 x 10^9 cell/L was 11 days (range 8-16) with median days from AHCT to ANC < 0.5 of 5 days (range 5-6). Median number of days of ANC < 0.1 and < 0.5 were 2 (range 1-5) and 5 days (range 3-9), respectively. Median time to fever was 8 days from AHCT (n = 8, range 7-12), and all except one were attributed to engraftment syndrome. Median length of stay was 18 days (range 15-21). Median pRBC and platelet transfusions were 0 (range 0-3) and 2 (range 0-11), respectively. For the SOC patients, engraftment timing was similar, but 2 had HTN, 3/7 with fever had non-engraftment neutropenic fevers (NENF), and median pRBC and platelet transfusions were 1 (range 0-8) and 4 (range 1-14), respectively. **Conclusions:** The addition of plinabulin to pegfilgrastim did not add major toxicities after AHCT. Patients had elevated WBC on Day +2, low rates of NENF, and potentially less need for transfusion support. Plinabulin PK, quality of life data, and PROs will be presented. Adjusting the schedule of plinabulin to Day 3 may allow stem cells to reach the bone marrow niche prior exposure to plinabulin and thereby use the novel mechanism of action to shorten the duration of neutropenia.

Introduction: Though significant progress has been made in therapy and outcomes of multiple myeloma, real-world outcomes remain inferior compared to clinical trial settings. Access to treatment with novel agents including autologous stem cell transplant (ASCT) and immunotherapies is limited in developing countries, which may further compromise the outcomes. This study looks at consecutive patients with newly diagnosed multiple myeloma (NDMM) patients registered over a period of 12 months to estimate overall survival and factors influencing them. **Methods:** This is a retrospective analysis of 243 consecutive NDMM patients from January 2017 to December 2017. Data was collected from Electronic medical record for treatment received, outcomes and factors affecting outcomes were evaluated using Kaplan Meier log rank test in univariate and Cox regression model for multivariate analysis. **Results:** The median age of study population was 56 years (range, 27 to 79). FISH analysis was available in 93.8% of patients and revealed hyperdiploidy in 39.5%. High-risk cytogenetics (del 17p, t (4:14), t(14;16), and t (14;20) abnormalities were found in 34.9% of the patients. R-ISS was available for 95.47% of the patients with R-ISS I, II, and III in 19 (7.8%), 128 (52.7%), and 45 (18.5%) patients respectively. First-line treatment was VCd in 174 (75.7%) patients, VRd in 26(10.7%) patients, while18 (7.40%) patients received doublet. Only 20 (8.2%) patients could underwent ASCT and 56 (22.6%) received maintenance therapy. The median overall survival was 4.3 years. On univariate analysis, female gender, R-ISS stage, raised LDH, ECOG performance status 1 or less, ASCT and use of maintenance therapy were significantly associated with better OS. On multivariate analysis female gender, ECOG performance status 1 or less and use of maintenance therapy were independent predictor of better OS. **Conclusions:** Outcomes of multiple myeloma patients in our series are inferior as compared to reported outcomes in literature. Most of patient in this time period did not receive RVd induction, ASCT and or maintenance therapy and appropriate use of these modalities may improve outcomes.

Introduction: In the final analysis of the phase 2 randomized GRIFFIN study after all patients (pts) completed 1 year of follow-up post maintenance therapy, died or withdrew (median follow-up, 49.6 months), daratumumab (dara), lenalidomide (R), bortezomib and dexamethasone (D-RVd) led to a clinically meaningful progression-free survival benefit vs RVd (hazard ratio, 0.45; 95% CI, 0.21–0.95; P=0.032). Patient-reported outcome (PRO) data also showed that D-RVd pts who continued on maintenance treatment experienced greater improvements in health-related quality of life vs RVd alone. Here, we present item-level responses from the PRO instruments to understand the degree of change after treatment (tx) on singular concepts. **Methods:** Transplant-eligible (TE) pts with newly diagnosed multiple myeloma (NDMM) were randomized 1:1 to receive 4 D-RVd/RVd induction cycles, autologous stem cell transplant (ASCT), 2 D-RVd/RVd consolidation cycles, and up to 2 years' maintenance therapy with R ± dara. PRO data were collected using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30-item (EORTC QLQ-C30), EORTC QLQ Multiple Myeloma Module 20-item (EORTC QLQ-MY20), and EuroQol 5-level (EQ-5D-5L) tools. Questionnaires were completed at baseline, on day 1 of cycles (C) 2, 3, 5; on day 21 of C4; post ASCT consolidation (C6 D21); and after months 6, 12, 18, and 24 of maintenance. Frequency distribution, by tx group and by visit, were summarized for PRO items reporting on MM disease symptoms and functional impacts. **Results:** A total of 207 pts were randomized (D-RVd, n=104; RVd, n=103). For both D-RVd/DR and RVd/R, pts reported a reduction in disease symptoms and impacts; when questioned on the presence of these symptoms/impacts, a greater proportion answered "not at all/a little" during maintenance vs "quite a bit/very much" at baseline. For rigorous activities and disease-specific symptoms including hip pain, trouble taking a long walk, and need to rest, a higher proportion of pts in the D-RVd/DR vs the RVd/R arm reported no symptom/impact during maintenance. For example, for trouble taking a long walk, a similar proportion of pts reported "not at all" at baseline for D-RVd/DR versus RVd/R (31.8% vs 29.8%, respectively), but a greater proportion of D-RVd/DR pts reported "not at all" at maintenance month 6 (45.3% vs 37.2%), 12 (44.6% vs 37.1%), 18 (37.2% vs 33.3%), and 24 (50.0% vs 43.5%). There were no differences in pts responding "not at all" between D-RVd/DR and RVd/R for pain in back, arm/shoulder, or chest; being tired; pain interfering with activities; and limitations of usual activities. **Conclusions:** The addition of dara to RVd/R in TE pts with NDMM led to meaningful reductions in disease symptoms/impact, with a higher proportion of D-RVd/DR pts reporting no symptom/impact after tx on items related to pain in hip, trouble taking a long walk, and needing to rest, compared to RVd/R.

Incidence, risk factors and impact of supraventricular tachycardia (SVT) with high dose therapy melphalan among myeloma patients undergoing autologous stem cell transplant (HDT/ASCT)

Kathryn Simon[1], Nisha Joseph[1], Anant Mandawat[1], Craig Hofmeister[1], Mala Shanmugam[1], Jonathan Kaufman[1], Michael Graiser[1], Sarah Wyman[1], Oyinda Adisa[1], Manali Rupji[1], Tom Matich[1], Vikas Gupta[1], Madhav Dhodapkar[1], Amelia Langston[1], Sagar Lonial[1], Ajay Nooka[1]

[1]Winship Cancer Institute at Emory University, Atlanta, GA, USA

Introduction: High dose therapy melphalan followed by autologous stem cell transplant (HDT/ASCT) confers an overall survival (OS) advantage and is the mainstay of frontline therapy among transplant-eligible myeloma patients. Melphalan is an arrhythmogenic chemotherapy but the incidence of developing peri-transplant supraventricular tachycardia (SVT) and its impact on OS has not been well described. We performed a single institutional analysis of 2970 patients undergoing HDT/ASCT from 2000-2021 to evaluate the incidence, risk factors and the long-term impact of SVT during the peri-transplant period. **Methods:** Variables of interest were extracted from Clinical Data Warehouse (CDW), a Structured Query Language (SQL) database as approved by Emory Institutional Review Board (IRB). A tiered algorithmic approach was developed to automate the extraction of data elements from the CDW utilizing SQL scripts which were validated by data from manual extraction and existing data from myeloma database and the transplant database. Broad tiered criteria included EKG obtained peri-transplant, anti-arrhythmic drug, ICU transfer, and cardiology consultation. **Results:** Of the 2970 patients, 614 (20.7%) underwent transplant between 2000-2010 and 445 (15%) were above the age of 70. Median age of transplant was 61.6 years, 48% had ≥ very good partial response (≥VGPR) pre-transplant, 59.6% had hypertension (HTN), 28.7% had coronary artery disease (CAD), 12.2% had prior β-blocker usage and 10.7% had prior arrhythmia. 948 (31.9%) had an EKG during the peri transplant period. 203 (6.8%) developed SVT and 155 (5.2%) required transfer to ICU. The median age of patients that developed SVT was higher (62.88 vs 60.8 years, p< 0.01) and length of stay (LOS) was increased by a day for patients that had SVT peri-transplant (16 vs 15 days, p< 0.001). Risk factors for developing SVT include HTN: 66.5% vs 56.4%, p< 0.001,

Here, we present item-level responses from the PRO instruments to understand the degree of change after treatment (tx) on singular concepts. **Methods:** Transplant-eligible (TE) pts with newly diagnosed multiple myeloma (NDMM) were randomized 1:1 to receive 4 D-RVd/RVd induction cycles, autologous stem cell transplant (ASCT), 2 D-RVd/RVd consolidation cycles, and up to 2 years' maintenance therapy with R ± dara. PRO data were collected using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30-item (EORTC QLQ-C30), EORTC QLQ Multiple Myeloma Module 20-item (EORTC QLQ-MY20), and EuroQol 5-level (EQ-5D-5L) tools. Questionnaires were completed at baseline, on day 1 of cycles (C) 2, 3, 5; on day 21 of C4; post ASCT consolidation (C6 D21); and after months 6, 12, 18, and 24 of maintenance. Frequency distribution, by tx group and by visit, were summarized for PRO items reporting on MM disease symptoms and functional impacts. **Results:** A total of 207 pts were randomized (D-RVd, n=104; RVd, n=103). For both D-RVd/DR and RVd/R, pts reported a reduction in disease symptoms and impacts; when questioned on the presence of these symptoms/impacts, a greater proportion answered "not at all/a little" during maintenance vs "quite a bit/very much" at baseline. For rigorous activities and disease-specific symptoms including hip pain, trouble taking a long walk, and need to rest, a higher proportion of pts in the D-RVd/DR vs the RVd/R arm reported no symptom/impact during maintenance. For example, for trouble taking a long walk, a similar proportion of pts reported "not at all" at baseline for D-RVd/DR versus RVd/R (31.8% vs 29.8%, respectively), but a greater proportion of D-RVd/DR pts reported "not at all" at maintenance month 6 (45.3% vs 37.2%), 12 (44.6% vs 37.1%), 18 (37.2% vs 33.3%), and 24 (50.0% vs 43.5%). There were no differences in pts responding "not at all" between D-RVd/DR and RVd/R for pain in back, arm/shoulder, or chest; being tired; pain interfering with activities; and limitations of usual activities. **Conclusions:** The addition of dara to RVd/R in TE pts with NDMM led to meaningful reductions in disease symptoms/impact, with a higher proportion of D-RVd/DR pts reporting no symptom/impact after tx on items related to pain in hip, trouble taking a long walk, and needing to rest, compared to RVd/R.

Incidence, risk factors and impact of supraventricular tachycardia (SVT) with high dose therapy melphalan among myeloma patients undergoing autologous stem cell transplant (HDT/ASCT)

Kathryn Simon[1], Nisha Joseph[1], Anant Mandawat[1], Craig Hofmeister[1], Mala Shanmugam[1], Jonathan Kaufman[1], Michael Graiser[1], Sarah Wyman[1], Oyinda Adisa[1], Manali Rupji[1], Tom Matich[1], Vikas Gupta[1], Madhav Dhodapkar[1], Amelia Langston[1], Sagar Lonial[1], Ajay Nooka[1]

[1]Winship Cancer Institute at Emory University, Atlanta, GA, USA

Introduction: High dose therapy melphalan followed by autologous stem cell transplant (HDT/ASCT) confers an overall survival (OS) advantage and is the mainstay of frontline therapy among transplant-eligible myeloma patients. Melphalan is an arrhythmogenic chemotherapy but the incidence of developing peri-transplant supraventricular tachycardia (SVT) and its impact on OS has not been well described. We performed a single institutional analysis of 2970 patients undergoing HDT/ASCT from 2000-2021 to evaluate the incidence, risk factors and the long-term impact of SVT during the peri-transplant period. **Methods:** Variables of interest were extracted from Clinical Data Warehouse (CDW), a Structured Query Language (SQL) database as approved by Emory Institutional Review Board (IRB). A tiered algorithmic approach was developed to automate the extraction of data elements from the CDW utilizing SQL scripts which were validated by data from manual extraction and existing data from myeloma database and the transplant database. Broad tiered criteria included EKG obtained peri-transplant, anti-arrhythmic drug, ICU transfer, and cardiology consultation. **Results:** Of the 2970 patients, 614 (20.7%) underwent transplant between 2000-2010 and 445 (15%) were above the age of 70. Median age of transplant was 61.6 years, 48% had ≥ very good partial response (≥VGPR) pre-transplant, 59.6% had hypertension (HTN), 28.7% had coronary artery disease (CAD), 12.2% had prior β-blocker usage and 10.7% had prior arrhythmia. 948 (31.9%) had an EKG during the peri transplant period. 203 (6.8%) developed SVT and 155 (5.2%) required transfer to ICU. The median age of patients that developed SVT was higher (62.88 vs 60.8 years, p< 0.01) and length of stay (LOS) was increased by a day for patients that had SVT peri-transplant (16 vs 15 days, p< 0.001). Risk factors for developing SVT include HTN: 66.5% vs 56.4%, p< 0.001,

CAD: 35.3% vs 25.6%, p< 0.001, β-blockers: 15.5% vs 10.6%, p< 0.001, arrhythmias: 15.9% vs 8.2%, p< 0.001, age ≥70: 18.4% vs 13.4%, p< 0.001. 30-day readmit rate was 8.5% (SVT vs no SVT: 11.9% vs 6.9%, p< 0.001), 30 day mortality was 0.8% (SVT vs no SVT: 2.4% vs 0.1%, p< 0.001), 100 day mortality was 2% (SVT vs no SVT: 4.4% vs 0.8%, p< 0.001). The OS was 9 years (SVT vs no SVT: 9.3 vs 6.6 years, p< 0.001). This difference extended to patients transplanted between 2011-2021 where the OS was 10.5 years (SVT vs no SVT: 10.82 vs 6.53, p< 0.001). H/o β-blocker use was the only independent risk factor for shortened OS (HR 1.25 95% CI (1.029-1.52), p=0.025). **Conclusions:** While the data aligns with known findings of melphalan as an arrhythmogenic agent, the current data identifies prior h/o β-blocker use as an independent risk factor for shortened OS. SVT peri-transplant resulted in longer hospital LOS, significantly increased 30-day mortality and 100-day mortality and had an impact on OS. The current data supports preventive strategies aimed at decreasing the incidence of SVT peri-transplant.

Daratumumab, bortezomib, lenalidomide, and dexamethasone (DVRd) vs daratumumab, carfilzomib, lenalidomide and dexamethasone (DKRd) as induction therapy in newly diagnosed multiple myeloma

Carlyn Rose Tan[1], Kylee Maclachlan[2], David Nemirovsky[3], Andriy Derkach[1], Malin Hultcrantz[2], Hani Hassoun[2], Sham Mailankody[2], Urvi Shah[2], Dhwani Patel[1], Tala Shekarkhand[1], Colin Rueda[1], Oscar Lahoud[1], Gunjan Shah[1], Michael Scordo[1], David Chung[4], Heather Landau[4], Sergio Giralt[1], Saad Usmani[1], Alexander Lesokhin[1], Neha Korde[2]

[1]Memorial Sloan Kettering Cancer Center, New York City NY, USA; [2]Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York City NY, USA; [3]Department of Epidemiology & Biostatistics, Memorial Sloan Kettering Cancer Center; [4]Bone Marrow Transplant and Cellular Therapy, Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: DVRd and DKRd are promising induction regimens for newly diagnosed multiple myeloma (NDMM), resulting in deep responses and high minimal residual disease (MRD) negativity rates. Our prior work demonstrated PFS benefit in high-risk (HR) NDMM receiving KRd versus VRd. Herein, we examined early outcomes associated with DVRd and DKRd induction for transplant eligible patients (pts) with NDMM. **Methods:** We conducted a chart review study with NDMM pts treated with DVRd (N=82) and compared outcomes with pts treated with DKRd (N=79), of which 68 were on study (NCT03290950) at our center (10/5/2017 to 12/29/22). Data cutoff for analysis was 1/31/23. Pts with </=1 cycle of other therapy (tx) were included (N=10). Pts with ongoing tx with < 4 cycles of quadruplet tx were excluded. Bone marrow biopsies (BMBx) were typically performed for MRD evaluation (flow cytometry; 10-5 sensitivity) before stem cell collection or at the end of cycle (C) 8. **Results:** Median age was 66 (IQR 59-70) for DVRd- and 59 (50-65) for DKRd-treated pts (P< 0.001). DVRd group had 68% White and 16% Black, while DKRd had 78% White and 8% Black. The majority of pts in both groups were RISS Stage 2 (DVRd RISS 1/2/3: 21%/75%/5%; D-KRd: 38%/57%/5%). With HR cytogenetics defined as 1q+, t(4;14), t(14;16), t(14;20), del(17p), 26/71 (37%) in DVRd and 38/77 (49%) in DKRd had cytogenetic results that met HR criteria (P=0.12). Median number of cycles was 6 (4-6) for DVRd and 8 (7-8) for DKRd (P< 0.001). At data cutoff, 31 (39%) DVRd- and 25 (32%) DKRd-treated pts received upfront ASCT. Best ORR was 96% and 100% for DVRd and DKRd (P=0.2), respectively. Within C8 of tx, 61 (74%) DVRd- and 72 (91%) DKRd-treated pts achieved >/=VGPR (P=0.005). There were 2 pts with stable disease and 1 progressive disease as best response on DVRd. 62 DVRd and 72 DKRd pts had a BMBx /=CR on DVRd and DKRd, respectively. Among pts with BMBx </=C6, 13/60 (22%) and 36/69 (52%) were MRD negative for DVRd and DKRd, respectively. Multivariable analysis (age, gender, race, stage, cytogenetic risk, number of cycles) demonstrated that age was associated with improved CR rate (OR 1.07, 95%CI 1.02-1.13, P=0.004). There was a trend toward improved CR rate within C8 with DKRd compared to DVRd (OR 2.7, 95%CI 0.99-8.33; P=0.053). **Conclusions:** In this single center chart review, DVRd was compared to DKRd. Importantly, DKRd pts were primarily from a clinical trial, perhaps affecting demographics of the groups (DVRd group had older pts and more Black pts; DKRd group had more HR pts and received more cycles due to trial design). Best ORR was similar for both groups. Although CR rate was greater with DKRd, on multivariable analysis there was a trend toward better CR rate with DKRd vs DVRd without reaching statistical significance. Data with follow-up outcomes, including HR subgroups, will be presented at the meeting.

Introduction: Serum B-cell maturation antigen (sBCMA) levels have emerged as potential biomarkers for disease monitoring with prognostic value in patients with multiple myeloma (MM). **Methods:** We evaluated sBCMA distribution with Elecsys® sBCMA assay (Roche Diagnostics International Ltd, Rotkreuz, Switzerland) and its potential prognostic role in patients with MM and smoldering MM (sMM) by a single institution. Patients with sBCMA values outside of measuring range (1.2-900 ng/mL) were excluded. **Results:** 166 patients diagnosed from 2018 to 2020 were included (median follow up: 38 months). The median age was 67 years (range 50-93

years), 101 (61%) were males, 122 had symptomatic MM and 44 had SMM. The baseline mean sBCMA value was 162 ng/mL (SD 169) for patients with MM and 19.4 ng/mL (SD 16.5) for SMM. In a subset of patients with MM, there were available data at the time of first (n=68) and second (n=20) disease progression. At first disease progression, the mean sBCMA value was 102 ng/mL (SD 148), whereas at second disease progression the mean sBCMA value was 169 ng/mL (SD 275). There was a general trend towards decreasing sBCMA values from baseline to first disease progression (mean difference -82.9ng/mL, 95%CI: -118 to -47.8ng/mL, p< 0.0001). In general, the results were consistent among the risk stratification subgroups based on ISS staging. The sample size was rather small for the second disease progression timepoint (the estimated mean difference of 56.1% which corresponds to a 43.9% decrease from baseline, p = 0.028). The baseline mean sBCMA value was lower in patients without documented disease progression (103 ng/mL, SD 107) compared with patients who had one (200 ng/mL, SD 194) or two (198 ng/mL, SD 185) disease progressions during the follow-up period. In addition, there was no meaningful association between sBCMA baseline values and best response during first line treatment. Furthermore, patients with symptomatic MM were categorized as low (n=61) or high expressors (n=61) based on sBCMA expression at baseline; low expressors had baseline sBCMA values below 113 ng/mL (median) and high expressors had baseline sBCMA values ≥ 113 ng/mL. The median progression-free survival (PFS) was 24.7 months (95%CI: 20.1 to 32.4) for high expressors and 53.7 months (95%CI: 26.9 to not reached) for low expressors (HR 1.67, log-rank p=0.031). In the subgroup analysis according to ISS, a significant association became evident only for patients with ISS 3 (HR 2.24, 95%CI: 1.12 to 4.48, p=0.023, high versus low expressors). Interestingly, high expressors had a median OS of 58.4 months (95%CI: 46 to not reached) compared with low expressors (median OS not reached, HR 2.05, log-rank p = 0.039). **Conclusions:** MM patients with high baseline sBCMA levels seem to have a dismal prognosis compared to those with low sBCMA levels. Sequential evaluation of sBCMA in prospective studies will determine the value of incorporating sBCMA measurement in the clinical practice.

Solo G-CSF versus chemotherapy-based stem cell mobilization in Hungarian transplantation-eligible patients

Laszlo Varoczy[1], Nora Obajed Al-Ali[1], Laszlo Imre Pinczes[1], Arpad Illes[1]

[1]University of Debrecen

Introduction: Autologous peripheral stem cell transplantation (APSCT) is still a crucial part of the therapy in eligible multiple myeloma (MM) patients. The gold standard of stem cell mobilization is administering high-dose cyclophosphamide followed by granulocyte colony stimulating factor (G-CSF), however the usage of G-CSF alone can also be an effective option **Methods:** Our aim was to compare the efficacy and safety of solo G-CSF versus chemotherapy-based stem cell mobilization in our Hungarian patient population. **Results:** We reviewed 210 patients' data who underwent stem cell mobilization between 2018 and 2022. Solo G-CSF was administered in 104 cases while 106 patients received chemotherapy (cyclophosphamide or VTD-PACE regimen) which was followed by the cytokine stimulation. In the solo G-CSF group, there was a significantly higher need for plerixafor administration (45% vs 13%, p< 0.001), unsuccessful stem cell mobilization was more frequent (11% vs 3%, p=0.024) and the mean amount of collected stem cells was significantly lower (6.9 vs. 9.8 x 10^6/bwkg, p< 0.001) than in the chemotherapy group. On the other hand, infections were less frequent (4% vs 27%, p< 0.001) and the number of days spent in hospital was significantly lower (6 vs 14 days, p< 0.001). The number of therapy lines before stem cell collection had no effect on any of the outcomes. Plerixafor was more frequenty administered in those who received lenalidomide or daratumumab as part of the induction therapy than in those who were treated by other regimens (41% vs 23%, p=0.007 and 78% vs 2 %, p< 0.001, respectively). The amount of collected stem cells was negatively influenced by previous lenalidomide therapy (p< 0.001) and there was a marked, but not significant difference in the ratio of unsuccessful mobilization attempts (11.3% vs 4.3%, p=0.056). Interestingly, R-ISS stages and treatment responses had no impact on the efficacy of the mobilization procedure. **Conclusions:** The administration of solo G-CSF is a safe method of stem cell mobilization, however the higher rate of plerixafor administration and unsuccessful attempts may question its cost-effectivity.

Clinical features and outcome patterns of newly diagnosed multiple myeloma patients who are candidate for transplant: a single center experience in Paraguay

Alana Von Glasenapp[1], Elvira Enciso[1], Aline Paats[1], Lidiane Andino Neves[1]

[1]Hospital Central del Instituto de Prevision Social

Introduction: The advances in the management of multiple myeloma (MM) have yielded improved outcomes. Both the use of novel therapies and consolidation with autologous stem-cell transplantation have demonstrated superior overall response and progression-free survival rates. However, these are not readily available in most Latin American countries. Here, we aim to characterize the clinico-epidemiological features, treatment and outcome patterns of newly diagnosed MM patients in a referral center in Paraguay. **Methods:** We conducted a retrospective observational cohort study. Data were collected from clinical records, classified according to the International Staging System (ISS) and stage of the disease. Clinical and epidemiological characteristics were analyzed as well as access to first-line transplantation in newly diagnosed MM patients diagnosed from 2018 to 2022. **Results:** We included 127 patients aged 65 years and younger. Most patients were male (52%), with IgG immunoglobulin subtype (69%), and the most frequently with Kappa light chain (59%). According to the ISS classification, 40% of the patients were ISS2 at diagnosis, 34% ISS1 and 26% ISS3. Stage at diagnosis were: IIA in 32% of patients, IIB 24%, IIIA 20%, IIIB 13% IA 10% and IB 1%. Initial clinical presentations included

years), 101 (61%) were males, 122 had symptomatic MM and 44 had SMM. The baseline mean sBCMA value was 162 ng/mL (SD 169) for patients with MM and 19.4 ng/mL (SD 16.5) for SMM. In a subset of patients with MM, there were available data at the time of first (n=68) and second (n=20) disease progression. At first disease progression, the mean sBCMA value was 102 ng/mL (SD 148), whereas at second disease progression the mean sBCMA value was 169 ng/mL (SD 275). There was a general trend towards decreasing sBCMA values from baseline to first disease progression (mean difference -82.9ng/mL, 95%CI: -118 to -47.8ng/mL, p< 0.0001). In general, the results were consistent among the risk stratification subgroups based on ISS staging. The sample size was rather small for the second disease progression timepoint (the estimated mean difference of 56.1% which corresponds to a 43.9% decrease from baseline, p = 0.028). The baseline mean sBCMA value was lower in patients without documented disease progression (103 ng/mL, SD 107) compared with patients who had one (200 ng/mL, SD 194) or two (198 ng/mL, SD 185) disease progressions during the follow-up period. In addition, there was no meaningful association between sBCMA baseline values and best response during first line treatment. Furthermore, patients with symptomatic MM were categorized as low (n=61) or high expressors (n=61) based on sBCMA expression at baseline; low expressors had baseline sBCMA values below 113 ng/mL (median) and high expressors had baseline sBCMA values ≥ 113 ng/mL. The median progression-free survival (PFS) was 24.7 months (95%CI: 20.1 to 32.4) for high expressors and 53.7 months (95%CI: 26.9 to not reached) for low expressors (HR 1.67, log-rank p=0.031). In the subgroup analysis according to ISS, a significant association became evident only for patients with ISS 3 (HR 2.24, 95%CI: 1.12 to 4.48, p=0.023, high versus low expressors). Interestingly, high expressors had a median OS of 58.4 months (95%CI: 46 to not reached) compared with low expressors (median OS not reached, HR 2.05, log-rank p = 0.039). **Conclusions:** MM patients with high baseline sBCMA levels seem to have a dismal prognosis compared to those with low sBCMA levels. Sequential evaluation of sBCMA in prospective studies will determine the value of incorporating sBCMA measurement in the clinical practice.

Introduction: The advances in the management of multiple myeloma (MM) have yielded improved outcomes. Both the use of novel therapies and consolidation with autologous stem-cell transplantation have demonstrated superior overall response and progression-free survival rates. However, these are not readily available in most Latin American countries. Here, we aim to characterize the clinico-epidemiological features, treatment and outcome patterns of newly diagnosed MM patients in a referral center in Paraguay. **Methods:** We conducted a retrospective observational cohort study. Data were collected from clinical records, classified according to the International Staging System (ISS) and stage of the disease. Clinical and epidemiological characteristics were analyzed as well as access to first-line transplantation in newly diagnosed MM patients diagnosed from 2018 to 2022. **Results:** We included 127 patients aged 65 years and younger. Most patients were male (52%), with IgG immunoglobulin subtype (69%), and the most frequently with Kappa light chain (59%). According to the ISS classification, 40% of the patients were ISS2 at diagnosis, 34% ISS1 and 26% ISS3. Stage at diagnosis were: IIA in 32% of patients, IIB 24%, IIIA 20%, IIIB 13% IA 10% and IB 1%. Initial clinical presentations included

anemia in 75% of the patients, 53% had renal failure, and 26% had bone lesions. The first line scheme in patients without renal failure was VTD (Bortezomib, Thalidomide, Dexamethasone), and patients with renal failure received CyBorD (Cyclophosphamide, Bortezomib, Dexamethasone). About 58% of the patients were able to access a transplant in the first line of treatment. The patients who did not have access to transplantation were due to progression during first line or death due to infectious causes. **Conclusions:** To our knowledge, this is the first study that characterizes Paraguayan patients with newly diagnosed MM, which also allows us to assess the number of patients accessing a standard treatment that achieves adequate responses to be able to undergo Autologous Bone Marrow Transplantation (BMT).

Stem cell mobilization and autologous stem cell transplantation after induction with bendamustine, prednisone and bortezomib (BPV) in 135 untreated myeloma patients with variable renal function

Song-Yau Wang[1], Susann Fricke[1], Tanja Holzhey[1], Vladan Vucinic[1], Georg-Nikolaus Franke[1], Uwe Platzbecker[1], Maximilian Merz[1], Wolfram Pönisch[1]

[1]University of Leipzig

Introduction: Autologous stem cell transplantation (ASCT) is the standard first line treatment for younger patients (pts) (< 70 years) with multiple myeloma (MM). Approximately 20-50 % of all pts already display an impaired kidney function at diagnosis. However, most of MM pts with severe renal dysfunction are excluded from ASCT studies. Bortezomib and bendamustine have both been identified as quickly acting and well-tolerated drugs for pts with MM-induced renal failure. In this retrospective study we analyzed the efficacy of a BPV induction therapy prior ASCT in newly diagnosed MM pts depending on the severity of renal impairment. Furthermore, additional information is needed on stem cell toxicity of BPV-induction using chemomobilization. **Methods:** Between October 2008 and November 2019, 135 pts with newly diagnosed MM were treated with BPV-induction consisting of bendamustine 60mg/m^2 on days 1 and 2, bortezomib 1.3mg/m^2 on days 1, 4, 8 and 11 and prednisone 100mg on days 1, 2, 4, 8 and 11. PBSC collection was performed 2-3 weeks after BPV induction. **Results:** The majority of pts (n=117; 87%) responded after median 2 (range 1-6) BPV-cycles with 9 sCR, 3 CR, 12 nCR, 39 VGPR and 54 PR. For stem cell mobilization, 111 pts received cyclophosphamide 4g/m^2 and 24 pts with severe renal failure or pre-existing heart disease 1-2g/m^2. Stem cell counts of CD34+≥20x10^6/L in the peripheral blood were achieved in 131 (97%) pts after a median of 12 (range 9-17) days. Further four pts (3%) with poor stem cell mobilization on day 15 received additional plerixafor. In 96 of 135 pts (71%) a single apheresis was sufficient to reach the target of 8x10^6 CD34+/kg. Transplant related mortality was 0.7%. Engraftment was successful in 134 of 135 pts. After first ASCT ORR increased to 99% with 33 sCR, 10 CR, 32 nCR, 41 VGPR and 17 PR. With a median observation time of 51 months, median PFS was 47 months and 60 months OS was 67%. Pts were divided into four groups depending on the severity of renal impairment: group A 13 pts with eGFR < 15mL/min, group B 15 pts with eGFR 15-29mL/min, group C 19 pts with eGFR 30-59mL/min and group D 88 pts with eGFR ≥60mL/min. At the time of diagnosis, 8 out of 13 pts in group A were dialysis dependent. We observed no significant difference in the median PFS between pts with normal/mild, moderate, severe renal dysfunction and renal failure/dialysis (50 vs 47 vs 34 vs 24 months, p=0.053) and in the 60 months OS (69 vs 72 vs 58 vs 70%, p=0.23). Following the ASCT, the renal response rate improved from 61% after BPV induction to 74% with 18 CRrenal (47%), 3 PRrenal (8%) and 7 MRrenal (18%). Four of the eight dialysis-dependent pts became dialysis-independent. **Conclusions:** BPV is a highly effective and well-tolerated induction-treatment protocol prior to ASCT in patients with MM-induced renal failure. Pretreatment with two cycles of BPV has no negative influence on stem cell mobilization and hematopoietic recovery after ASCT.

The changing landscape of peri-transplant adverse events with HDT/ASCT and the impact on long term outcomes for myeloma patients

Sarah Wyman[1], Nisha Joseph[1], Oyinda Adisa[2], Tom Matich[3], Madhusmita Behera[4], Michael Graiser[1], Kathryn Simon[1], Manali Rupji[1], Jonathan Kaufman[1], Craig Hofmeister[1], Vikas Gupta[1], Madhav Dhodapkar[1], Amelia Langston[1], Sagar Lonial[1], Ajay Nooka[4]

[1]Winship Cancer Institute at Emory University, Atlanta, GA, USA; [2]Data and Technology Shared Resource, Winship Cancer Institute of Emory University; [3]IT Data Solutions, Office of Information Technology; [4]Emory University School of Medicine

Introduction: High dose therapy followed by autologous stem cell transplant (HDT/ASCT) remains standard of care for newly diagnosed transplant-eligible patients with myeloma. Given the morbidity and mortality associated with HDT/ASCT, the decision to proceed with HDT/ASCT necessitates a careful discussion and shared decision making of risks vs benefits. With the changing landscape of improved supportive care, we reviewed the rates of both immediate and long-term impact of peri-transplant complications. **Methods:** Variables of interest were extracted from the Clinical Data Warehouse (CDW), a Structured Query Language (SQL) database. A tiered algorithmic approach was developed to automate the extraction of data elements from the CDW utilizing SQL scripts, which were manually validated. Neutropenic fever rates (ASCO definition), microbiology, radiology, and culture data were all used for our automated extraction. We used two time periods (decade 1: 2000-2010, decade 2: 2011-2021) to evaluate the changes by era. All values were reported as decade 1 vs decade 2, respectively. **Results:** For the 2,970 patients that underwent HDT/ASCT from 2000-2021, 614 (20.7%) received HDT/ASCT in decade 1. Median age at transplant was 58.1 (range, 27.1-77.4) vs 62.3 years (range, 16.8-79.9), p< 0.001. Patients ≥ 70 were transplanted more in decade 2 (5.9% vs 17.4%, p< 0.001). The time from diagnosis to HDT/ASCT was shorter [10.6 (2-157) vs 6.7 months (1-231), p< 0.0001]

anemia in 75% of the patients, 53% had renal failure, and 26% had bone lesions. The first line scheme in patients without renal failure was VTD (Bortezomib, Thalidomide, Dexamethasone), and patients with renal failure received CyBorD (Cyclophosphamide, Bortezomib, Dexamethasone). About 58% of the patients were able to access a transplant in the first line of treatment. The patients who did not have access to transplantation were due to progression during first line or death due to infectious causes. **Conclusions:** To our knowledge, this is the first study that characterizes Paraguayan patients with newly diagnosed MM, which also allows us to assess the number of patients accessing a standard treatment that achieves adequate responses to be able to undergo Autologous Bone Marrow Transplantation (BMT).

Introduction: High dose therapy followed by autologous stem cell transplant (HDT/ASCT) remains standard of care for newly diagnosed transplant-eligible patients with myeloma. Given the morbidity and mortality associated with HDT/ASCT, the decision to proceed with HDT/ASCT necessitates a careful discussion and shared decision making of risks vs benefits. With the changing landscape of improved supportive care, we reviewed the rates of both immediate and long-term impact of peri-transplant complications. **Methods:** Variables of interest were extracted from the Clinical Data Warehouse (CDW), a Structured Query Language (SQL) database. A tiered algorithmic approach was developed to automate the extraction of data elements from the CDW utilizing SQL scripts, which were manually validated. Neutropenic fever rates (ASCO definition), microbiology, radiology, and culture data were all used for our automated extraction. We used two time periods (decade 1: 2000-2010, decade 2: 2011-2021) to evaluate the changes by era. All values were reported as decade 1 vs decade 2, respectively. **Results:** For the 2,970 patients that underwent HDT/ASCT from 2000-2021, 614 (20.7%) received HDT/ASCT in decade 1. Median age at transplant was 58.1 (range, 27.1-77.4) vs 62.3 years (range, 16.8-79.9), p< 0.001. Patients ≥ 70 were transplanted more in decade 2 (5.9% vs 17.4%, p< 0.001). The time from diagnosis to HDT/ASCT was shorter [10.6 (2-157) vs 6.7 months (1-231), p< 0.0001]

anemia in 75% of the patients, 53% had renal failure, and 26% had bone lesions. The first line scheme in patients without renal failure was VTD (Bortezomib, Thalidomide, Dexamethasone), and patients with renal failure received CyBorD (Cyclophosphamide, Bortezomib, Dexamethasone). About 58% of the patients were able to access a transplant in the first line of treatment. The patients who did not have access to transplantation were due to progression during first line or death due to infectious causes. **Conclusions:** To our knowledge, this is the first study that characterizes Paraguayan patients with newly diagnosed MM, which also allows us to assess the number of patients accessing a standard treatment that achieves adequate responses to be able to undergo Autologous Bone Marrow Transplantation (BMT).

Stem cell mobilization and autologous stem cell transplantation after induction with bendamustine, prednisone and bortezomib (BPV) in 135 untreated myeloma patients with variable renal function

Song-Yau Wang[1], Susann Fricke[1], Tanja Holzhey[1], Vladan Vucinic[1], Georg-Nikolaus Franke[1], Uwe Platzbecker[1], Maximilian Merz[1], Wolfram Pönisch[1]

[1]University of Leipzig

Introduction: Autologous stem cell transplantation (ASCT) is the standard first line treatment for younger patients (pts) (< 70 years) with multiple myeloma (MM). Approximately 20-50 % of all pts already display an impaired kidney function at diagnosis. However, most of MM pts with severe renal dysfunction are excluded from ASCT studies. Bortezomib and bendamustine have both been identified as quickly acting and well-tolerated drugs for pts with MM-induced renal failure. In this retrospective study we analyzed the efficacy of a BPV induction therapy prior ASCT in newly diagnosed MM pts depending on the severity of renal impairment. Furthermore, additional information is needed on stem cell toxicity of BPV-induction using chemomobilization. **Methods:** Between October 2008 and November 2019, 135 pts with newly diagnosed MM were treated with BPV-induction consisting of bendamustine 60mg/m^2 on days 1 and 2, bortezomib 1.3mg/m^2 on days 1, 4, 8 and 11 and prednisone 100mg on days 1, 2, 4, 8 and 11. PBSC collection was performed 2-3 weeks after BPV induction. **Results:** The majority of pts (n=117; 87%) responded after median 2 (range 1-6) BPV-cycles with 9 sCR, 3 CR, 12 nCR, 39 VGPR and 54 PR. For stem cell mobilization, 111 pts received cyclophosphamide 4g/m^2 and 24 pts with severe renal failure or pre-existing heart disease 1-2g/m^2. Stem cell counts of CD34+≥20x10^6/L in the peripheral blood were achieved in 131 (97%) pts after a median of 12 (range 9-17) days. Further four pts (3%) with poor stem cell mobilization on day 15 received additional plerixafor. In 96 of 135 pts (71%) a single apheresis was sufficient to reach the target of 8x10^6 CD34+/kg. Transplant related mortality was 0.7%. Engraftment was successful in 134 of 135 pts. After first ASCT ORR increased to 99% with 33 sCR, 10 CR, 32 nCR, 41 VGPR and 17 PR. With a median observation time of 51 months, median PFS was 47 months and 60 months OS was 67%. Pts were divided into four groups depending on the severity of renal impairment: group A 13 pts with eGFR < 15mL/min, group B 15 pts with eGFR 15-29mL/min, group C 19 pts with eGFR 30-59mL/min and group D 88 pts with eGFR ≥60mL/min. At the time of diagnosis, 8 out of 13 pts in group A were dialysis dependent. We observed no significant difference in the median PFS between pts with normal/mild, moderate, severe renal dysfunction and renal failure/dialysis (50 vs 47 vs 34 vs 24 months, p=0.053) and in the 60 months OS (69 vs 72 vs 58 vs 70%, p=0.23). Following the ASCT, the renal response rate improved from 61% after BPV induction to 74% with 18 CRrenal (47%), 3 PRrenal (8%) and 7 MRrenal (18%). Four of the eight dialysis-dependent pts became dialysis-independent. **Conclusions:** BPV is a highly effective and well-tolerated induction-treatment protocol prior to ASCT in patients with MM-induced renal failure. Pretreatment with two cycles of BPV has no negative influence on stem cell mobilization and hematopoietic recovery after ASCT.

Neutropenic fever rates (ASCO definition), microbiology, radiology, and culture data were all used for our automated extraction. We used two time periods (decade 1: 2000-2010, decade 2: 2011-2021) to evaluate the changes by era. All values were reported as decade 1 vs decade 2, respectively. **Results:** For the 2,970 patients that underwent HDT/ASCT from 2000-2021, 614 (20.7%) received HDT/ASCT in decade 1. Median age at transplant was 58.1 (range, 27.1-77.4) vs 62.3 years (range, 16.8-79.9), p< 0.001. Patients ≥ 70 were transplanted more in decade 2 (5.9% vs 17.4%, p< 0.001). The time from diagnosis to HDT/ASCT was shorter [10.6 (2-157) vs 6.7 months (1-231), p< 0.0001]

and higher rates of ≥VGPR pre-transplant were achieved in decade 2 (12.5% vs 57.3%, p< 0.001). 71.6% of patients received melphalan 200 mg/m^2. C.diff occurred in 5.5% and respiratory infections in 3.3%, not different by decade. Increased incidence of SVT (4.6% vs 7.4%, p< 0.006), bacteremia (5 vs 8.9%, p< 0.001), neutropenic fevers (64.7 vs 82.4, p< 0.001), ICU transfers (2.6 vs 5.9%, p< 0.001) occurred in decade 2. Despite transplanting older patients, the rate of 30-day readmits (10.4 vs 8%; p=0.037), 30-day mortality (1.5% vs 0.7%, p=0.05) and 100-day mortality (3.6% vs 1.6%, p=0.002) decreased in decade 2. The OS improved in decade 2 (7.2 vs 10.5 years, p< 0.001). Developing bacteremia, c. diff, and respiratory infections peri-transplant as well as transplant age ≥70 did not have any impact on OS, however developing SVT (9.25 vs 6.6 years, p< 0.001) and ICU transfer peri-transplant (9.2 vs 6.3 years, p< 0.001) are associated with shorter OS. **Conclusions:** More elderly patients underwent HDT/ASCT in decade 2 and have gained the survival advantage the decade had to offer both from the benefit of modern induction therapies as seen by increased ≥VGPR rates pre-transplant as well as HDT/ASCT itself. Transplanting elderly patients did not have any impact on long term survival. Developing SVT and ICU transfer are associated with less optimal outcomes. The 30-day, 100-day mortality, re-admit rates have all improved in the last decade, allowing room for a meaningful discussion with patients favoring HDT/ASCT.

Autologous stem cell transplantation for multiple myeloma – a single center experience from India

Sanjeev Yadav[1], Faheema Hasan[1], Dinesh Chandra[1], Manish Kumar Singh[1], Khaiqur Rahman[1], Ruchi Gupta[1], Rajesh Kashyap[1], Soniya Nityanand[1]

[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences

Introduction: Autologous stem cell transplantation (ASCT) remains the standard of care for patients with newly diagnosed multiple myeloma (MM) despite the approval of novel agents. Numerous trials have demonstrated a progression-free survival (PFS) advantage with ASCT. To study the demographics, clinical profile, and outcomes of patients with MM undergoing ASCT at a tertiary care center in northern India. **Methods:** This is a medical records review of 29 patients with MM who underwent ASCT between 2007 and 2021. The demographics, clinical profile, induction regimen, details of ASCT, and outcomes were retrieved. Descriptive analysis, Progression Free Survival (PFS), and Overall Survival (OS) were determined. Data are expressed as median and interquartile range (IQR). **Results:** The median age of the cohort was 56 years (50-61) and 21 (72%) were males. The follow-up duration from diagnosis was 60 months (18-74). The most common immunoglobulin isotype was IgG kappa (28%) followed by IgG lambda (24%) and IgA kappa (21%). R-ISS staging was available for 26 patients and 21 of 26 (72%) had stage III disease. High-risk cytogenetics were identified in 19 patients (66%). Nine patients (47%) had t(4;14) and four (21%) had deletion 17p. Triplet induction consisting of Bortezomib, dexamethasone, and IMiD was the most common induction regimen (18, 62%). Two patients received quadruplet induction consisting of daratumumab, bortezomib, lenalidomide, and dexamethasone. The median time from diagnosis to transplant was 12 months (8-22). Most patients (24, 79%) were transplanted in first complete remission (CR1). The most common conditioning regimen was high dose melphalan, dosed at 200mg/m^2. Nine patients (31%) received a reduced dose of melphalan (140mg/m^2) in view of reduced GFR, poor ECOG performance status, secondary amyloidosis, and other co-morbidities. The median stem cell dose was 5.44 x10^6/kg (4.98-6.01 x 10^6/kg). The median time to engraftment was 9 days (8-10). Mucositis was the most common complication post ASCT (26, 90%), and grade 3/4 mucositis complicated seven transplants (24%). Three patients (10.3%) died during the post-ASCT neutropenic period secondary to sepsis. Eleven patients (42%) relapsed, and the median duration of remission (PFS) post-ASCT was 34 months (30.5-40.5) (Figure 1). Of those who relapsed, five (45.5%) died of disease progression, one died (9%) of myocardial infarction and five patients (45.5%) were alive at the time of the last follow-up. The OS was 89.7% with the median survival time post-ASCT being 39 months (7-60). **Conclusions:** ASCT remains the standard of care for patients with multiple myeloma, especially in lower-middle income countries where access to second-line therapies is limited.

Introduction: Multiple myeloma (MM) is a malignancy of terminally differentiated antibody-secreting plasma cells in the bone marrow with highly variable survival outcomes. Precise risk stratification not only plays a vital role in predicting patient prognoses, but critically can be used to develop risk-adapted treatment regimens. However, current risk stratification models do not adequately account for the heterogeneity of patients with new-diagnosed multiple myeloma (NDMM). **Methods:** In this retrospective, multicohort study, we collected clinical data from 1792 NDMM patients and formulated a weighted Myeloma Prognostic Score System (MPSS) risk model to predict overall survival (OS). Construction of the MPSS model was carried out based on the National Longitudinal Cohort of Hematological

and higher rates of ≥VGPR pre-transplant were achieved in decade 2 (12.5% vs 57.3%, p< 0.001). 71.6% of patients received melphalan 200 mg/m^2. C.diff occurred in 5.5% and respiratory infections in 3.3%, not different by decade. Rockefeller Cancer Institute, Department of Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, Arkansas, USA; [3]LeBow Institute for Myeloma Therapeutics and Jerome Lipper Center for Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts; [4]Myeloma Center, University of Arkansas for Medical Sciences

Introduction: Multiple myeloma (MM) is a malignancy of terminally differentiated antibody-secreting plasma cells in the bone marrow with highly variable survival outcomes. Precise risk stratification not only plays a vital role in predicting patient prognoses, but critically can be used to develop risk-adapted treatment regimens. However, current risk stratification models do not adequately account for the heterogeneity of patients with new-diagnosed multiple myeloma (NDMM). **Methods:** In this retrospective, multicohort study, we collected clinical data from 1792 NDMM patients and formulated a weighted Myeloma Prognostic Score System (MPSS) risk model to predict overall survival (OS). Construction of the MPSS model was carried out based on the National Longitudinal Cohort of Hematological

Diseases in China (NCT04645199) cohort, external validation cohort was created using TT2, TT3a, and TT3b cohorts from a series of randomized prospective studies from the University of Arkansas for Medical Sciences (UAMS). **Results:** Each risk factor was defined as its weighted value respectively according to their hazard ratio for OS (thrombocytopenia 2, elevated LDH 1, ISS III 2, one high-risk cytogenetic aberration [HRA] 1, and ≥2 HRA 2 points). In the training cohort, patients were furtherly stratified into four risk groups: MPSS I (22.5%, 0 points), II (17.6%, 1 points), III (38.6%, 2-3 points), and IV (21.3%, 4-7 points). MPSS risk stratification showed optimal discrimination, as well as calibration, of four risk groups with median OS of 91.0, 69.8, 45.0, and 28.0 months, for patients in MPSS I to IV groups (P< 0.001), respectively. Importantly, the MPSS model retained its prognostic value in the internal validation cohort and an independent external validation cohort, and exhibited significant risk distribution compared with conventional prognostic models (R-ISS, R2-ISS, and MASS). **Conclusions:** In conclusion, we formulated and validated the MPSS risk model to predict the prognosis of patients with MM using readily available standard clinical and genetic test data. The established MPSS profile shows a better performance in risk discrimination than the current R-ISS, R2-ISS, and MASS. A score-based risk stratification is derived, and identifies patients with high and ultra-high risk of death after diagnosis and may therefore aid the development of more personalized treatment strategies, especially for patients for whom current therapies are likely to fail.

Introduction: Due to the wide application of novel agents, the survival outcomes of patients with newly-diagnosed multiple myeloma (NDMM) have significantly improved in recent years. However, almost NDMM patients eventually relapse owing to the acquisition of drug resistance and sustained residual disease. However, the definitions of ER in MM vary from study to study. **Methods:** The study was based on the National Longitudinal Cohort of Hematological Diseases in China (NCT04645199). A total of 629 patients diagnosed with NDMM between January 2013 and December 2019 were included in this study. We evaluated different ER definitions and investigated the underlying relationship between ER with static risk distribution. **Results:** We first summarized all studies about ER published to date and found that relapse within 18 months from the initial treatment or within 12 months from SCT was mostly used to define early PD in many studies. Our findings indicate that ER18 could effectively balance the bias of ER definitions for patients with or without ASCT, as well as fulfill all requirements for a dynamic risk predictor. The ER18 population (114/587; 19.4%) presented with more aggressive biologic features compared to a reference cohort (P< 0.001), with a significant short median overall survival (OS) of 28.9 months. We also described the specific transitions from static risk profile to dynamic risk distribution in our cohort and then constructed a mixed-risk pattern to identify four novel populations with distinct survival outcomes (P< 0.001). A total of 367 (67.0%) patients presented with at least one high-risk feature: those with ISS III stage, elevated LDH, and HRCAs were classified as baseline high-risk (BHR) group; 86 (23.4%) patients experienced ER18 and further defined as mixed high-risk (MHR) population, and the remaining patients were classified as static high-risk (SHR). Within patients without BHR features, the dynamic risk event (ER18) occurred in 21(11.6%) patients, defined as functional high-risk (FHR). As expected, the MHR population had the worst outcomes with a median OS of 25.9 months (P< 0.001). Of note, FHR patients had similar survival compared to SHR patients (OS: not reached vs. 71.4 months; P=0.235; Figure 3B), supporting the importance of dynamic risk factor (ER18) as a prognostic factor and further suggesting that lack of durable response could exert an adverse impact on prognosis similar to baseline high-risk variables. Moreover, we confirmed that ER18 refined the predictive accuracy of the Revised International Staging System stage (R-ISS). **Conclusions:** ER18 maintains its significance as a predictor of prognosis in the multivariate analysis. The underlying correlation between clinical features at diagnosis and dynamic predictor (ER18) was demonstrated. Our results further indicated that ER18 was a refining factor for the R-ISS staging system and that the refined model could actualize a more valuable risk distribution.

Improving Anti-BCMA CAR-T functionality with novel immunomodulatory agent Iberdomide (CC220) in Multiple Myeloma

Adolfo Aleman[1], Ariel Kogan-Zajdman[1], Bhaskar Upadhyaya[1], Oliver Van Oekelen[1], Lucia Chen[1], Violetta Leshchenko[1], Sundar Jagannath[2], Samir Parekh[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [2]Mount Sinai Medical Center, New York, NY, USA

Introduction: Anti-B Cell maturation antigen (BCMA) targeting Chimeric Antigen Receptor T Cells (CAR-T) is a highly effective cellular therapy for Multiple Myeloma (MM). Despite CAR-T being a promising treatment, relapse is common and there is a subset of patients that do not respond at all. Our prior studies (Oekelen et al, Blood 2021) have shown that Iberdomide can activate T and NK cells while reducing exhaustion markers (TIGIT) in MM patients. Based on this, we hypothesize that Iberdomide, could improve anti-BCMA CAR-T cell therapy in anti-MM cytotoxicity. **Methods:** In this in vitro study, we evaluated the impact of Iberdomide on the persistence, proliferation, and activation of Anti-BCMA

Diseases in China (NCT04645199) cohort, external validation cohort was created using TT2, TT3a, and TT3b cohorts from a series of randomized prospective studies from the University of Arkansas for Medical Sciences (UAMS). **Results:** Each risk factor was defined as its weighted value respectively according to their hazard ratio for OS (thrombocytopenia 2, elevated LDH 1, ISS III 2, one high-risk cytogenetic aberration [HRA] 1, and ≥2 HRA 2 points). In the training cohort, patients were furtherly stratified into four risk groups: MPSS I (22.5%, 0 points), II (17.6%, 1 points), III (38.6%, 2-3 points), and IV (21.3%, 4-7 points). MPSS risk stratification showed optimal discrimination, as well as calibration, of four risk groups with median OS of 91.0, 69.8, 45.0, and 28.0 months, for patients in MPSS I to IV groups (P< 0.001), respectively. Importantly, the MPSS model retained its prognostic value in the internal validation cohort and an independent external validation cohort, and exhibited significant risk distribution compared with conventional prognostic models (R-ISS, R2-ISS, and MASS). **Conclusions:** In conclusion, we formulated and validated the MPSS risk model to predict the prognosis of patients with MM using readily available standard clinical and genetic test data. The established MPSS profile shows a better performance in risk discrimination than the current R-ISS, R2-ISS, and MASS. A score-based risk stratification is derived, and identifies patients with high and ultra-high risk of death after diagnosis and may therefore aid the development of more personalized treatment strategies, especially for patients for whom current therapies are likely to fail.

Introduction: Anti-B Cell maturation antigen (BCMA) targeting Chimeric Antigen Receptor T Cells (CAR-T) is a highly effective cellular therapy for Multiple Myeloma (MM). Despite CAR-T being a promising treatment, relapse is common and there is a subset of patients that do not respond at all. Our prior studies (Oekelen et al, Blood 2021) have shown that Iberdomide can activate T and NK cells while reducing exhaustion markers (TIGIT) in MM patients. Based on this, we hypothesize that Iberdomide, could improve anti-BCMA CAR-T cell therapy in anti-MM cytotoxicity. **Methods:** In this in vitro study, we evaluated the impact of Iberdomide on the persistence, proliferation, and activation of Anti-BCMA

CAR-T cells. Using custom spectral flow cytometry panels, we captured dynamics of the CAR-T cell phenotypic composition and proliferation in response to Iberdomide treatment. Additionally, we analyzed the functional effect of Iberdomide on CAR-T cells by quantifying antigen specific cytokine production and cytotoxic activity. **Results:** Our results demonstrate that treatment with Iberdomide significantly decreases the presence of transcription factors Ikaros and Aiolos in CAR-T cells by 24 hours ($p< 0.01$). Incubation with Iberdomide promoted persistence and proliferation in IL-2 starved cells in vitro. After 96 hours, CAR-T cells treated with Iberdomide expressed significantly more Ki67 expression ($p< 0.01$) and were significantly more viable compared to control (median viability 80% compared to 30%, $p< 0.001$). The presence of Iberdomide resulted in increased activation of CAR-T cells with an increase of hallmark activation markers such as HLADR, and CD69 ($p< 0.05$) and decrease in the expression of TIGIT ($p=0.041$). Iberdomide increased antigen specific cytokine production against BCMA expressing MM cells by 6 hours, specifically increasing the antigen specific production of IL-2, IL-17a, and TNFa by CAR-T cells ($p< 0.01$). Iberdomide enhanced antigen specific toxicity by CAR-T cells by 46% compared to control by 48 hours ($p< 0.001$). These findings suggest that Iberdomide can keep CAR-T cells in an activated state counteracting exhaustion and promote the survival and function of CAR-T cells, addressing two major mechanisms underlying CAR-T failure and resistance. **Conclusions:** Our study provides evidence that combination treatment with Iberdomide can enhance the persistence and proliferation of anti-BCMA CAR-T cells in vitro. Moreover, Iberdomide induced activation of CAR-T cells leads to improved antigen specific cytokine production and cytotoxic activity. These findings highlight the potential of Iberdomide as an adjunctive therapy to overcome CAR-T cell resistance ultimately improving the therapeutic efficacy of anti-BCMA CAR-T therapy in patients with MM. We are planning further studies to validate these promising results in vivo to ultimately translate into clinical application.

ETV4-dependent transcriptional plasticity maintains MYC expression and results in IMiD resistance in multiple myeloma

Benjamin Barwick[1], Paola Neri[2], Ines Tagoug[2], Ranjan Maity[2], Caleb Stein[3], Noemie Leblay[2], Sungwoo Ahn[2], Holly Lee[2], Remi Tilmont[2], Jonathan Keats[4,5], Sagar Lonial[1], Leif Bergsagel[3], Lawrence Boise[1], Nizar Bahlis[2]

[1]Winship Cancer Institute, Emory University, Atlanta, GA, USA; [2]Arnie Charbonneau Cancer Institute, University of Calgary; [3]Mayo Clinic Arizona; [4]TGen; [5]City of Hope

Introduction: Immunomodulatory Drugs (IMiDs) improve outcomes in multiple myeloma (MM), in part, by targeting IKZF1 and IKZF3 for degradation. Almost all MM patients receive IMiDs as front-line therapy, and they eventually develop resistance. Downregulation and mutations have been reported in CRBN, the direct binding target of IMiDs, but these only account for a small fraction of IMiD-resistant cases. Here, we show that the ETS factor ETV4 binds the same elements as IKZF1 to maintain enhancer function, MYC expression, and IMiD resistance. **Methods:** Myeloma cells were treated with 10 uM lenalidomide (Len) and responses were measured by MTT assays, RNAseq, and ChIPseq. ETV4 ablation was performed by CRISPR/Cas9. Computational analyses used R/Bioconductor and CoMMpass data from Genomic Data Commons with IA19 outcome data. **Results:** Len treatment of 12 myeloma cell lines resulted in IKZF3 degradation in all cases, but MYC downregulation only occurred in cells where growth was inhibited. ChIP-seq showed IKZF1 bound both proximal and telomeric distal MYC enhancers as well as immunoglobulin (Ig) super-enhancers, that are often translocated to MYC and other oncogenes. However, both IMiD-sensitive (MM1S) and resistant (RPMI8226) myeloma cells showed IKZF1 binding to these elements. Similarly, Len treatment resulted in the depletion of chromatin-bound IKZF1 in both MM1S and RPMI8226 at DUSP22/IRF4, MYC, and Ig super-enhancers. In contrast, the transcriptional co-activators P300 and BRD4 were depleted from chromatin in MM1S upon Len treatment but remained unchanged in RPMI8226 despite IKZF1 depletion, suggesting other factors may be substituting for IKZF1 to maintain RPMI8226 enhancer function. Bioinformatic analyses identified expression of the ETS factor ETV4 as associated with IMiD response in myeloma cell lines and enrichment of the ETV4 consensus binding motif "AGGAAG" at IKZF1-bound regions. ETV4 ChIP-seq showed a 79% overlap with IKZF1-bound regions including those at the IRF4/DUSP22, MYC, and Ig super-enhancers. CRISPR/Cas9-mediated ablation of ETV4 in RPMI8226 resulted in Len downregulating MYC, and reducing RPMI8226 cell growth. Finally, ETV4 expression was found in 10% of newly-diagnosed patients from the CoMMpass and POLLUX trials and each study showed ETV4 expression was associated with poor progression-free survival and upregulated upon relapse. **Conclusions:** These data indicate that the downregulation of MYC is a "bottleneck" in IMiD responses and that this requires enhancer decommissioning. Depletion of chromatin-bound IKZF1 is not a differentiating factor in IMiD responses. Rather, the determining factor is whether or not enhancer function is dependent upon IKZF1 binding resulting in MYC downregulation and IMiD-mediated growth inhibition. In this regard, we have identified ETV4 transcriptional plasticity in 10% of newly diagnosed myeloma as a mediator of IMiD resistance. These data provide a rationale for targeting enhancer co-factors (e.g. P300) in combination with IMiDs.

Introduction: Immunomodulatory Drugs (IMiDs) improve outcomes in multiple myeloma (MM), in part, by targeting IKZF1 and IKZF3 for degradation. Almost all MM patients receive IMiDs as front-line therapy, and they eventually develop resistance. Downregulation and mutations have been reported in CRBN, the direct binding target of IMiDs, but these only account for a small fraction of IMiD-resistant cases. Here, we show that the ETS factor ETV4 binds the same elements as IKZF1 to maintain enhancer function, MYC expression, and IMiD resistance. **Methods:** Myeloma cells were treated with 10 uM lenalidomide (Len) and responses were measured by MTT assays, RNAseq, and ChIPseq. ETV4 ablation was performed by CRISPR/Cas9. Computational analyses used R/Bioconductor and CoMMpass data from Genomic Data Commons with IA19 outcome data. **Results:** Len treatment of 12 myeloma cell lines resulted in IKZF3 degradation in all cases, but MYC downregulation only occurred in cells where growth was inhibited. ChIP-seq showed IKZF1 bound both proximal and telomeric distal MYC enhancers as well as immunoglobulin (Ig) super-enhancers, that are often translocated to MYC and other oncogenes. However, both IMiD-sensitive (MM1S) and resistant (RPMI8226) myeloma cells showed IKZF1 binding to these elements. Similarly, Len treatment resulted in the depletion of chromatin-bound IKZF1 in both MM1S and RPMI8226 at DUSP22/IRF4, MYC, and Ig super-enhancers. In contrast, the transcriptional co-activators P300 and BRD4 were depleted from chromatin in MM1S upon Len treatment but remained unchanged in RPMI8226 despite IKZF1 depletion, suggesting other factors may be substituting for IKZF1 to maintain RPMI8226 enhancer function. Bioinformatic analyses identified expression of the ETS factor ETV4 as associated with IMiD response in myeloma cell lines and enrichment of the ETV4 consensus binding motif "AGGAAG" at IKZF1-bound regions. ETV4 ChIP-seq showed a 79% overlap with IKZF1-bound regions including those at the IRF4/DUSP22, MYC, and Ig super-enhancers. CRISPR/Cas9-mediated ablation of ETV4 in RPMI8226 resulted in Len downregulating MYC, and reducing RPMI8226 cell growth. Finally, ETV4 expression was found in 10% of newly-diagnosed patients from the CoMMpass and POLLUX trials and each study showed ETV4 expression was associated with poor progression-free survival and upregulated upon relapse. **Conclusions:** These data indicate that the downregulation of MYC is a "bottleneck" in IMiD responses and that this requires enhancer decommissioning. Depletion of chromatin-bound IKZF1 is not a differentiating factor in IMiD responses. Rather, the determining factor is whether or not enhancer function is dependent upon IKZF1 binding resulting in MYC downregulation and IMiD-mediated growth inhibition. In this regard, we have identified ETV4 transcriptional plasticity in 10% of newly diagnosed myeloma as a mediator of IMiD resistance. These data provide a rationale for targeting enhancer co-factors (e.g. P300) in combination with IMiDs.

Introduction: Resistance to IMiDs is a major problem in the treatment of MM and is explained in only a fraction of cases by alterations of the CRBN pathway that reduce the ability of IMiDs to deplete IKZF1 and IKZF3. Here, we show that IMiDs synergize with EP300 inhibitors (EP300i) but that transcriptional heterogeneity can overcome IKZF1, IKZF3, and EP300 dependency to maintain MYC and IRF4 expression and mediate IMiD resistance. **Methods:** Human myeloma cell lines (HMCL) were treated with pomalidomide (POM) and EP300i (GNE781 and CCS1477) and proliferation was measured by cell count. IKZF1, IKZF3, MYC, and IRF4 protein levels were measured by Western blot. Vk*MYC;hCRBN mice were treated with POM (50 mpk) and/or G781 (15 or 3.75 mpk) for two weeks and survival was measured. shRNA knockdown and doxycycline-inducible lentiviral overexpression were used for functional characterization of BATF proteins. Analysis of CoMMpass used IA17 with RNAseq from Genomic Data Commons. **Results:** Treatment with POM resulted in a universal degradation of IKZF1 and IKZF3 across 48 HMCL, but this did not correlate with effects on proliferation, which was more closely linked with MYC and IRF4 downregulation. MYC and particularly IRF4 downregulation could also be achieved with EP300i, which showed single-agent activity in a clinically predictive murine model of MM but had a narrow therapeutic index. POM+EP300i resulted in further downregulation of IRF4 and MYC, induced synergistic responses in HMCL, was tolerable in mice with murine MM, and significantly extended their survival. ChIPseq showed that 79% of EP300 binding sites were also bound by IKZF1. HMCL resistant to POM+EP300i were defined by high expression of ETS and BATF AP-1 factors. When expressed, HMCL were dependent upon BATF, BATF2, and BATF3, and their knock-down induced sensitization to POM+EP300i while their overexpression promoted resistance and maintained IRF4 and MYC expression. Mechanistically, BATF2, IRF4, and IKZF1 bound the same sites in the IGH and DUSP22/IRF4 super-enhancers suggesting BATF factors bind with IRF4 at AP-1:IRF composite elements (AICE). Overexpression of a BATFH55Q, which cannot interact with IRF4, failed to induce resistance to POM+EP300i. Finally, BATF expression was associated with reduced PFS and upregulated upon relapse in patients treated with IMiDs in CoMMpass. **Conclusions:** These data indicate that MYC and IRF4 downregulation are critical events for IMiD responses, which can be augmented through combined EP300i. The overlap of P300 and IKZF1 binding sites provides a molecular explanation for the observed synergy between POM and EP300i. These data provide a strong preclinical rationale for the ongoing clinical trial of POM+CCS1477 (NCT04068597). Finally, the expression of BATF AP-1 factors can mediate IMiD resistance by alleviating IKZF1 and IKZF3 dependency, likely through cooperative binding with IRF4 at essential myeloma super-enhancers that maintain MYC and IRF4 expression.

Introduction: The treatment pattern evolution for Multiple Myeloma (MM) in Portugal remains unclear, particularly how therapeutic innovation impacted clinical practice. This study aimed to describe and characterize MM treatment landscape over a 5-year period in Portugal. **Methods:** A retrospective longitudinal multicenter study was conducted through secondary data from electronic health records of 11 Portuguese National Health Service hospitals between Sep/2017-Aug/2022. MM patient population was identified based on drug consumption data of MM-specific therapies (e.g., proteasome inhibitors, immunomodulators, anti-CD38 mAbs). Patient drug consumption profile was analyzed, and MM treatment regimens identified through clustering of concomitant antineoplastic drugs. Treatment patterns were characterized based on patient dynamics (naïve, ongoing, switch, drop-out), stem cell transplant (SCT) eligibility (eligible (SCT-E) vs non-eligible (SCT-NE)), and treatment lines (1L to 4L+). Outcomes included population characterization (patient number, age, sex (M:F) ratio), regimen patient share per treatment line and dynamic subgroups. Time-to-event analysis was carried between two consecutive 5-year time series (Sep/2012-Aug/2017 and Sep/2017-Aug/22) to estimate variation in treatment duration (TD) and time to next treatment (TTNT). **Results:** The treated MM population increased by 53% during the 5-year period (2017: N=825; 2022: N=1266). Age and sex distribution remained stable, with a median age of 70 years and 1,2:1 sex ratio in 2022. Naïve patients increased by 22%, averaging a 5% yearly growth, with no major shift in SCT eligibility split (1:1 ratio in 2022). Treatment line analysis showed a positive trend in patients achieving 3L+, with an increase of 12% to 21% from

Time-to-event analysis was carried between two consecutive 5-year time series (Sep/2012-Aug/2017 and Sep/2017-Aug/22) to estimate variation in treatment duration (TD) and time to next treatment (TTNT). **Results:** The treated MM population increased by 53% during the 5-year period (2017: N=825; 2022: N=1266). Age and sex distribution remained stable, with a median age of 70 years and 1,2:1 sex ratio in 2022. Naïve patients increased by 22%, averaging a 5% yearly growth, with no major shift in SCT eligibility split (1:1 ratio in 2022). Treatment line analysis showed a positive trend in patients achieving 3L+, with an increase of 12% to 21% from

2017 to 2022. Treatment drop-out decreased in 2L to 3L and 3L to 4L+, with a drop-out rate of 17% and 19% per switch subgroup, respectively, in 2022. Main 1L regimens in SCT-E (VCd and VTd) and SCT-NE subgroups (VMP and VCd) remained stable, with daratumumab-based regimens increase in 2022 in all subgroups. Patient share in maintenance therapy increased from 5% to 16% in the overall treated population, dominated by lenalidomide in 2022. The 2L and 3L treatment pattern changed considerably, with daratumumab-based regimens dominating patient share in 2022 (2L-43%; 3L-35%). In 4L+ a heterogenous treatment pattern emerged, with no standard of care identified, being carfilzomib- and daratumumab-based regimens the most relevant in 2022. Overall median TD increased in SCT-E subgroup from 5 to 19 months between time series, driven by maintenance therapy, and remained stable for SCT-NE patients (10 months). Regarding TTNT, median time increased between 3L to 4L+ in SCT-E patients from 5.5 to 9 months. **Conclusions:** MM treatment landscape changed during a 5-year period, characterized by an increase in treated patients, patients achieving advanced treatment lines, and improved access to therapeutic innovation in earlier treatment stages of the disease.

Altered lipid metabolism in IMiD/CELMoD resistant multiple myeloma confers novel and targetable vulnerabilities

Sarah Bird[1,2], Yitao Xu[3], Fernando Sialana[1], Marco Licciardello[1], Harvey Che[1], Saleh Tamin[4], Habib Bouguenina[1], Yura Grabovska[1], Enze Liu[5], Salomon Morales[1], Yakinthi Chrisochoidou[1], Yigen Li[1], Shannon Martin[1], Amy Wilson[1], Erin Flynt[4], Brian Walker[5], Jyoti Choudhary[1], Paul Clarke[1], Hector Keun[3], Charlotte Pawlyn[1]

[1]The Institute of Cancer Research; [2]Royal Marsden Hospital; [3]Imperial College London; [4]Bristol Myers Squibb; [5]Melvin and Bren Simon Comprehensive Cancer Center, Division of Hematology and Oncology, School of Medicine, Indiana University

Introduction: IMiDs/CELMoDs are a cornerstone of myeloma treatment; however a major barrier to improving patient outcomes is the inevitable development of drug resistance. Understanding resistance mechanisms is critical to enable the advancement of targeted treatment strategies. **Methods:** Acquired IMiD/CELMoD resistant MM1s and H929 myeloma cell lines were characterised by whole exome sequencing, RNA-seq and proteomics. A genome-wide loss-of-function CRISPR screen was carried out in Iberdomide (Iber)-resistant MM1s; gene effect scores were calculated with the Chronos model and compared to parental MM1s using data from the DepMap portal. Membrane Bound Transcription Factor Peptidase Site 1 (MBTPS1) inhibitor PF-429242 was used to inhibit activation of the Sterol Regulatory-Element Binding Protein (SREBP) pathway. Stable isotope labelling experiments using 13C6-glucose assessed lipid synthesis. Using unpaired patient RNA-seq data, lipid gene transcript levels were compared between 736 newly diagnosed patients and 270 patients relapsing on lenalidomide. **Results:** Quantitative proteomic analysis identified common changes in lipid synthesis pathways, including the SREBP pathway, across the resistant cell lines. Stearoyl-CoA Desaturase (SCD), a key effector of the SREBP pathway, was one of only 5 proteins with significantly altered expression in all 6 resistant lines compared to control (log2FCs ranging from -0.37 to -1.50 (adj $p < 0.05$)). A genome-wide CRISPR screen using Iber-resistant MM1s cells identified potential new dependencies (gene effect score -0.5 in parental cells) in 47 genes including SCD and MBTPS1. MBTPS1 is critical for activation of the SREBP pathway and demonstrated one of the largest changes in gene effect (-1.4 vs –0.3). PF-429242 showed significantly greater reduction in cell proliferation in the IMiD/CELMoD resistant H929 cells compared to controls. 13C6-glucose labelling experiments showed that in Iber-resistant MM1s and H929 (compared to controls) the proportion of newly synthesised palmitic and stearic acid was reduced. The oleic acid/stearic acid and palmitoleic acid/palmitic acid ratios were also decreased, suggesting the flux of fatty acid desaturation catalysed by SCD was reduced. The fraction of glucose-derived lipogenic acetyl-CoA was also reduced in the resistant lines, indicating that resistance decreased glucose contribution to fatty acid synthesis with potential use of alternative carbon sources. There was a trend for increased synthesis of saturated fatty acids with PF-429242 treatment in Iber-resistant H929, but not its control. In patient RNA-seq data several fatty acid synthesis genes were significantly differentially expressed, including SCD and MBTPS1, suggesting the changes seen in cell lines may be replicated in patient data. **Conclusions:** The development of IMiD/CELMoD resistance is associated with alterations in lipid metabolism, suggesting a role in resistance biology that may confer novel and targetable vulnerabilities.

Introduction: Multiple myeloma (MM) is a hematological malignancy characterized by an accumulation of clonal plasma cells (PCs) in the bone marrow (BM). Gain and/or amplification of 1q21 (1q21+) is one of the most common cytogenetic abnormalities in MM patients with poor prognostic impact and correlated with a reduced response to proteasome inhibition (PI). Moreover, the incidence of the amplification of chromosome 1q in patients with pre-malignant smoldering myeloma (SMM) is about 40%. The 1q21 region is known to contain several upregulated genes that have been suggested to drive disease aggressiveness in 1q21+ patients. However,

2017 to 2022. Treatment drop-out decreased in 2L to 3L and 3L to 4L+, with a drop-out rate of 17% and 19% per switch subgroup, respectively, in 2022. Main 1L regimens in SCT-E (VCd and VTd) and SCT-NE subgroups (VMP and VCd) remained stable, with daratumumab-based regimens increase in 2022 in all subgroups. Patient share in maintenance therapy increased from 5% to 16% in the overall treated population, dominated by lenalidomide in 2022. The 2L and 3L treatment pattern changed considerably, with daratumumab-based regimens dominating patient share in 2022 (2L-43%; 3L-35%). In 4L+ a heterogenous treatment pattern emerged, with no standard of care identified, being carfilzomib- and daratumumab-based regimens the most relevant in 2022. Overall median TD increased in SCT-E subgroup from 5 to 19 months between time series, driven by maintenance therapy, and remained stable for SCT-NE patients (10 months). Regarding TTNT, median time increased between 3L to 4L+ in SCT-E patients from 5.5 to 9 months. **Conclusions:** MM treatment landscape changed during a 5-year period, characterized by an increase in treated patients, patients achieving advanced treatment lines, and improved access to therapeutic innovation in earlier treatment stages of the disease.

Introduction: IMiDs/CELMoDs are a cornerstone of myeloma treatment; however a major barrier to improving patient outcomes is the inevitable development of drug resistance. Understanding resistance mechanisms is critical to enable the advancement of targeted treatment strategies. **Methods:** Acquired IMiD/CELMoD resistant MM1s and H929 myeloma cell lines were characterised by whole exome sequencing, RNA-seq and proteomics. A genome-wide loss-of-function CRISPR screen was carried out in Iberdomide (Iber)-resistant MM1s; gene effect scores were calculated with the Chronos model and compared to parental MM1s using data from the DepMap portal. Membrane Bound Transcription Factor Peptidase Site 1 (MBTPS1) inhibitor PF-429242 was used to inhibit activation of the Sterol Regulatory-Element Binding Protein (SREBP) pathway. Stable isotope labelling experiments using 13C6-glucose assessed lipid synthesis. Using unpaired patient RNA-seq data, lipid gene transcript levels were compared between 736 newly diagnosed patients and 270 patients relapsing on lenalidomide. **Results:** Quantitative proteomic analysis identified common changes in lipid synthesis pathways, including the SREBP pathway, across the resistant cell lines. Stearoyl-CoA Desaturase (SCD), a key effector of the SREBP pathway, was one of only 5 proteins with significantly altered expression in all 6 resistant lines compared to control (log2FCs ranging from -0.37 to -1.50 (adj $p < 0.05$)). A genome-wide CRISPR screen using Iber-resistant MM1s cells identified potential new dependencies (gene effect score -0.5 in parental cells) in 47 genes including SCD and MBTPS1. MBTPS1 is critical for activation of the SREBP pathway and demonstrated one of the largest changes in gene effect (-1.4 vs –0.3). PF-429242 showed significantly greater reduction in cell proliferation in the IMiD/CELMoD resistant H929 cells compared to controls. 13C6-glucose labelling experiments showed that in Iber-resistant MM1s and H929 (compared to controls) the proportion of newly synthesised palmitic and stearic acid was reduced. The oleic acid/stearic acid and palmitoleic acid/palmitic acid ratios were also decreased, suggesting the flux of fatty acid desaturation catalysed by SCD was reduced. The fraction of glucose-derived lipogenic acetyl-CoA was also reduced in the resistant lines, indicating that resistance decreased glucose contribution to fatty acid synthesis with potential use of alternative carbon sources. There was a trend for increased synthesis of saturated fatty acids with PF-429242 treatment in Iber-resistant H929, but not its control. In patient RNA-seq data several fatty acid synthesis genes were significantly differentially expressed, including SCD and MBTPS1, suggesting the changes seen in cell lines may be replicated in patient data. **Conclusions:** The development of IMiD/CELMoD resistance is associated with alterations in lipid metabolism, suggesting a role in resistance biology that may confer novel and targetable vulnerabilities.

Introduction: Multiple myeloma (MM) is a hematological malignancy characterized by an accumulation of clonal plasma cells (PCs) in the bone marrow (BM). Gain and/or amplification of 1q21 (1q21+) is one of the most common cytogenetic abnormalities in MM patients with poor prognostic impact and correlated with a reduced response to proteasome inhibition (PI). Moreover, the incidence of the amplification of chromosome 1q in patients with pre-malignant smoldering myeloma (SMM) is about 40%. The 1q21 region is known to contain several upregulated genes that have been suggested to drive disease aggressiveness in 1q21+ patients. However,

the mechanisms driving the high-risk disease progression associated with 1q21+ have not been identified. This study aims to identify new druggable targets in the 1q21 region. **Methods:** We purified PCs from BM samples of 18 newly diagnosed MM patients. In addition, a cohort of 11 smoldering (SMM) was included in the study. Fluorescent in situ hybridization analysis was performed in purified CD138+ PCs in all patients to access copy number alterations in the 1q21 region. The expression profile of all 29 samples was generated using GeneChip ClariomD Arrays (Affymetrix Inc., Santa Clara, CA, USA). The smar package was used to identify differentially expressed genes between 1q21+ and control samples. **Results:** Among the most significant upregulated genes in our analysis, we identified the expression of PYGOPUS 2 (PYGO2), a downstream component of the Wnt signaling pathway, to be significantly upregulated in CD138+ MM cells with 1q21+ as compared to those without 1q21+ ($p= 0.0008$). Additionally, we found a significant positive correlation between gene expression and the 1q21 copy number ($p= < 0.0001$, $r= 0.6738$), correlated with 1q21 copy number but not with disease stage (SMM vs. MM). Moreover, we assessed PYGO2 mRNA and protein expression levels in a panel of MM human cell lines (HMCLs) carrying 1q21+. HMCL OCI-MY5 was used as a negative control. Our results showed that PYGO2 was higher in HMCLs with 1q21+. Furthermore, we evaluated the mRNA and protein expression levels of PYGO2 in HMCLs resistant to carfilzomib, showing that the expression of PYGO2 was consistently upregulated. Next, to investigate the functional role of PYGO2 in patients with 1q21, we generated a knockdown of PYGO2 in HMCL JJN3 using short hairpin RNA (shRNA). We found that PYGO2 transcripts were significantly downregulated in shPYGO2 when compared to scramble control. Notably, cells lacking PYGO2 have an increased rate of cell death when compared with the scramble cell line. **Conclusions:** In conclusion, our results show that the expression of PYGO2 is significantly upregulated in MM patients carrying 1q21+, and that PYGO2 inhibition by shRNA leads to an increase in cell death in HMCLs with 1q21+. Overall, our data indicate that targeting PYGO2 could represent a novel strategy to treat MM patients with 1q21+.

Introduction: Immunomodulatory imide drugs (IMiDs), such as lenalidomide, are vital agents in the therapeutic arsenal against multiple myeloma (MM). IMiDs directly promote MM cell death via cell cycle arrest and stimulate anti-tumour immune responses in the bone marrow (BM) niche. Lack of amino acid conservation between human and mouse orthologues of Cereblon (Crbn), the IMiD binding protein, render mice resistant to IMiDs. Given this, preclinical evaluation of IMiDs' pleiotropic mechanisms of action is hindered by a lack of immunocompetent MM mouse models displaying drug sensitivity. Notably, substitution of an isoleucine in murine Crbn with the analogous human valine residue (CrbnI391V) confers IMiD sensitivity to mouse cells. Here we investigate lenalidomide sensitivity in two immunocompetent MM mouse models where either the recipient mice or engrafted tumour cells harbour a humanised CrbnI391V gene. **Methods:** C57BL/6-CrbnI391V or C57BL/KaLwRij mice were intravenously inoculated with Vk*MYC or 5TGM1-CrbnI391V cells, respectively. MM tumour burden was monitored weekly by serum paraprotein quantification or bioluminescence (BLI) imaging. After tumour establishment, mice received daily intraperitoneal injections of 10mg/kg lenalidomide or 4% DMSO. C57BL/6-CrbnI391V mice (n=8-9/group) were treated for 28-days beginning at week 7 and C57BL/KaLwRij mice (n=8/group) received 14-days of treatment from week 2. Endpoint BM and splenic GFP+ tumour burden was assessed by flow cytometry. **Results:** We aimed to separately model: (1) lenalidomide-mediated BM microenvironment anti-myeloma immune responses in C57BL/6-CrbnI391V mice transplanted with Vk*MYC cells, and (2) lenalidomide-induced direct cytotoxicity in C57BL/KaLwRij mice transplanted with 5TGM1-CrbnI391V cells. Lenalidomide produced modest, non-significant reductions in whole body, BM and splenic Vk*MYC tumour burden in C57BL/6-CrbnI391V mice (t-tests, $p>0.05$). In contrast, lenalidomide's antiproliferative effects significantly delayed 5TGM1-CrbnI391V tumour growth in C57BL/KaLwRij mice. Compared to DMSO treatment, lenalidomide treated mice showed a 46.4% decrease in whole body BLI signal (two-way ANOVA, $p< 0.05$), as well as 50.4% and 58.2% reductions in paraprotein intensity (t-test, $p< 0.001$) and BM tumour burden (t-test, $p< 0.05$), respectively. **Conclusions:** Inadequate anti-myeloma efficacy of lenalidomide in the Vk*MYC model, where only the host C57BL/6-CrbnI391V mice displayed IMiD sensitivity, highlights the need for a fully IMiD-susceptible murine system. As such, a 5TGM1-CrbnI391V transplant C57BL/KaLwRij-CrbnI391V mouse model is under development. So far, we have demonstrated that CrbnI391V expression sensitises the 5TGM1 cell line to lenalidomide's direct, antiproliferative effects in vivo. C57BL/6-CrbnI391V mice have been backcrossed onto the C57BL/KaLwRij strain for 6 generations and future studies will investigate the synergy of lenalidomide-mediated tumoricidal and immunomodulatory anti-myeloma actions utilising this novel mouse model.

Introduction: In multiple myeloma (MM) and other neoplasias, it its challenging to target therapeutically tumor cells with loss of function (LOF) for tumor suppressor genes (TSGs), because pharmacological mechanisms to restore the function(s) of such genes are not considered to be readily feasible, in contrast to e.g., inhibition of oncogenic drivers. We reasoned, however, that, LOF for TSGs in MM cells leads to de-repressed cell growth, it may not necessarily protect tumor cells from immune attack. We thus explored the hypothesis that CRISPR-based loss of function of TSGs in MM cell lines may still be associated with substantial response to immune effector cells such as NK cells, which have the advantage to kill tumor cells across HLA barriers. **Methods:** We examined our genome-scale or focused CRISPR screens for LOF (CRISPR-based gene editing) or gain of function (GOF, CRISPR activation) in MM lines (KMS11, LP1 and MM1S) exposed to allogeneic donor-derived NK cells (vs. control cultures without NK cells) and specificallt evaluated the performance of genes known to represent recurrent TSGs based on genomic data of MM patient samples or cell lines; as well as candidate TSGs, based on results from genome-scale CRISPR gene editing screens (e.g., CERES or CHRONOS scores >0.4 in multiple DepMap releases and TPM>1 [RNA-seq]) in the same cell lines as the NK cell resistance screens. These analyses sought to identify any TSGs whose LOF may potentially alter the response of MM cells to NK cells. **Results:** Overall, 34 genes were identified as top recurrent TSGs in MM patient samples (e.g., based on prior genomic studies) or based on in vitro CRISPR knockout screens. These genes were evaluated for their metrics of sgRNA enrichment or depletion in genome-scale CRISPR gene editing or activation screens in the context of exposure to NK cells. These genes included known and recurrent TSGs (e.g., PTEN, FAM46C, TP53, RB1) as well as other, previously underappreciated candidate TSGs (e.g., HIF1A, ASXL1, ATRX). Perturbation of none of these genes was identified to meet criteria for association with significant resistance to allogeneic donor-derived NK cells (log2FC>1.0, at least 3-4 sgRNAs with enrichment upon CRISPR KO or depletion with CRISPR activation, p-value < 0.05, depletion [or enrichment] rank < 100) in any of the 3 MM cell lines examined in LOF or GOF CRISPR screens for NK cell resistance. In fact, for a limited set of cases (e.g., PTEN in KMS11 cells), KO of a TSG was associated with sensitization to NK cell treatment. These in-house results with MM cells exposed to NK cells are concordant with results for these TSGs in CRISPR screens of non-MM cells treated with cytotoxic T-cells (e.g., 4T1 or RENCA cells; GSE149933). **Conclusions:** MM cells deficient for diverse TSGs are equally responsive to NK cells as their TSG-proficient counterparts. NK cell-based therapies may thus be a promising approach to target TSG-deficient MM cells for which specific pharmacological therapies are not currently available.

Bottlebrush prodrugs as triplex combination therapies for multiple myeloma

Alexandre Detappe[1], Hung Nguyen[2], Irene Ghobrial[3], Peter Ghoroghchian[4], Jeremiah Johnson[2]

[1]Institut de Cancéroloie Strasbourg Europe; [2]MIT; [3]Dana-Farber Cancer Institute; [4]Ceptur Therapeutics

Introduction: Current anticancer agents continue to face substantial challenges, including inherently narrow therapeutic indexes (TIs) as well as suboptimal therapeutic combinations stemming from mixtures of active pharmaceutical ingredients (APIs) with dissimilar properties. While nanomedicine-based platforms for drug delivery can potentially address these challenges, key questions remain such as i/ will synergies of free drug combinations translate to nanoparticles, or should synergies be screen in the context of nanoparticles?, and ii/ are multi-drug-laden nanoparticles better than mixtures of single-drug-laden nanoparticles? **Methods:** To evaluate the efficacy of Btz monotherapy, a Btz-BPD was designed to enable a 25-fold increase in API dosing compared to Btz alone, while maintaining tolerable toxicity in mice. The Btz-BPD was tested in vivo using subcutaneous and orthotopic MM models, assessing tumor progression and survival outcomes. Furthermore, BPDs carrying Btz, Pom, and Dex were synthesized for combination therapies. In vitro studies were conducted to analyze the synergistic, additive, or antagonistic patterns of the BPD combination nanomedicines compared to their free drug counterparts. Mathematical modeling was employed to provide insights into the underlying mechanisms and explain the observed results. **Results:** The Btz-BPD monotherapy demonstrated a significant reduction in tumor progression and improved survival in both subcutaneous and orthotopic MM models. Furthermore, BPDs carrying combinations of Btz, Pom, and Dex exhibited distinct in vitro patterns of synergy, additivity, or antagonism, differing from their free drug counterparts. Importantly, statistical mixtures of the three drugs in BPDs outperformed free drug combinations, single-drug BPD mixtures, and antagonistic 3-drug BPDs. Quantitative analysis using a mathematical model confirmed that statistical 3-drug BPDs were more likely to deliver a synergistic drug ratio to cells compared to mixtures of single-drug BPDs. **Conclusions:** Our results address critical gaps in the field of nanomedicine and provides new design principles for combination nanomedicines. The BPD platform offers promising strategies for improving existing mono- and combination therapies for MM. By demonstrating the superiority of statistical 3-drug BPDs over other formulations, our findings open doors for more effective and rational approaches to combination therapy in

Introduction: In multiple myeloma (MM) and other neoplasias, it its challenging to target therapeutically tumor cells with loss of function (LOF) for tumor suppressor genes (TSGs), because pharmacological mechanisms to restore the function(s) of such genes are not considered to be readily feasible, in contrast to e.g., inhibition of oncogenic drivers. We reasoned, however, that, LOF for TSGs in MM cells leads to de-repressed cell growth, it may not necessarily protect tumor cells from immune attack. We thus explored the hypothesis that CRISPR-based loss of function of TSGs in MM cell lines may still be associated with substantial response to immune effector cells such as NK cells, which have the advantage to kill tumor cells across HLA barriers. **Methods:** We examined our genome-scale or focused CRISPR screens for LOF (CRISPR-based gene editing) or gain of function (GOF, CRISPR activation) in MM lines (KMS11, LP1 and MM1S) exposed to allogeneic donor-derived NK cells (vs. control cultures without NK cells) and specificallt evaluated the performance of genes known to represent recurrent TSGs based on genomic data of MM patient samples or cell lines; as well as candidate TSGs, based on results from genome-scale CRISPR gene editing screens (e.g., CERES or CHRONOS scores >0.4 in multiple DepMap releases and TPM>1 [RNA-seq]) in the same cell lines as the NK cell resistance screens. These analyses sought to identify any TSGs whose LOF may potentially alter the response of MM cells to NK cells. **Results:** Overall, 34 genes were identified as top recurrent TSGs in MM patient samples (e.g., based on prior genomic studies) or based on in vitro CRISPR knockout screens. These genes were evaluated for their metrics of sgRNA enrichment or depletion in genome-scale CRISPR gene editing or activation screens in the context of exposure to NK cells. These genes included known and recurrent TSGs (e.g., PTEN, FAM46C, TP53, RB1) as well as other, previously underappreciated candidate TSGs (e.g., HIF1A, ASXL1, ATRX). Perturbation of none of these genes was identified to meet criteria for association with significant resistance to allogeneic donor-derived NK cells (log2FC>1.0, at least 3-4 sgRNAs with enrichment upon CRISPR KO or depletion with CRISPR activation, p-value < 0.05, depletion [or enrichment] rank < 100) in any of the 3 MM cell lines examined in LOF or GOF CRISPR screens for NK cell resistance. In fact, for a limited set of cases (e.g., PTEN in KMS11 cells), KO of a TSG was associated with sensitization to NK cell treatment. These in-house results with MM cells exposed to NK cells are concordant with results for these TSGs in CRISPR screens of non-MM cells treated with cytotoxic T-cells (e.g., 4T1 or RENCA cells; GSE149933). **Conclusions:** MM cells deficient for diverse TSGs are equally responsive to NK cells as their TSG-proficient counterparts. NK cell-based therapies may thus be a promising approach to target TSG-deficient MM cells for which specific pharmacological therapies are not currently available.

Introduction: Current anticancer agents continue to face substantial challenges, including inherently narrow therapeutic indexes (TIs) as well as suboptimal therapeutic combinations stemming from mixtures of active pharmaceutical ingredients (APIs) with dissimilar properties. While nanomedicine-based platforms for drug delivery can potentially address these challenges, key questions remain such as i/ will synergies of free drug combinations translate to nanoparticles, or should synergies be screen in the context of nanoparticles?, and ii/ are multi-drug-laden nanoparticles better than mixtures of single-drug-laden nanoparticles? **Methods:** To evaluate the efficacy of Btz monotherapy, a Btz-BPD was designed to enable a 25-fold increase in API dosing compared to Btz alone, while maintaining tolerable toxicity in mice. The Btz-BPD was tested in vivo using subcutaneous and orthotopic MM models, assessing tumor progression and survival outcomes. Furthermore, BPDs carrying Btz, Pom, and Dex were synthesized for combination therapies. In vitro studies were conducted to analyze the synergistic, additive, or antagonistic patterns of the BPD combination nanomedicines compared to their free drug counterparts. Mathematical modeling was employed to provide insights into the underlying mechanisms and explain the observed results. **Results:** The Btz-BPD monotherapy demonstrated a significant reduction in tumor progression and improved survival in both subcutaneous and orthotopic MM models. Furthermore, BPDs carrying combinations of Btz, Pom, and Dex exhibited distinct in vitro patterns of synergy, additivity, or antagonism, differing from their free drug counterparts. Importantly, statistical mixtures of the three drugs in BPDs outperformed free drug combinations, single-drug BPD mixtures, and antagonistic 3-drug BPDs. Quantitative analysis using a mathematical model confirmed that statistical 3-drug BPDs were more likely to deliver a synergistic drug ratio to cells compared to mixtures of single-drug BPDs. **Conclusions:** Our results address critical gaps in the field of nanomedicine and provides new design principles for combination nanomedicines. The BPD platform offers promising strategies for improving existing mono- and combination therapies for MM. By demonstrating the superiority of statistical 3-drug BPDs over other formulations, our findings open doors for more effective and rational approaches to combination therapy in

MM. These results have broader implications for enhancing current cancer treatments and advancing the field of nanomedicine.

Lenalidomide: rash or no rash, that is the question

Akshitha Devaraj[1], David Sparksman[2], Cesar Gomez[2]

[1]Norfolk and Norwich University Hospitals; [2]Norfolk and Norwich University Hospital Foundation Trust

Introduction: Lenalidomide is an immunomodulatory (IMID) drug used as a backbone in many myeloma therapy regimens. Its mechanism of action is complex exerting a pleiotropic anti-myeloma effect in vitro including immune-modulation, anti-angiogenic, anti-inflammatory and anti-proliferative effects. However, the relative in vivo contribution of each is poorly understood. The toxicity profile of Lenalidomide is well known. It includes skin rash, pruritus, and photosensitivity. The mechanism by which lenalidomide may cause skin toxicity is not fully understood. However, studies suggest that lenalidomide can cause an immune-mediated reaction in the skin, particularly through T cell dysregulation. Lenalidomide is known to increase the production of Th1 cells, which are involved in the immune response. It is hypothesised that the increase in Th1 cells leads to an overactive immune response resulting in inflammation and tissue damage. Recently we have observed a high incidence of skin toxicity in patients receiving lenalidomide. This may have an impact on treatment, compliance and potentially result in cessation of treatment. **Methods:** We reviewed the notes and collected data from the medical records of all patients who received lenalidomide over a 3-year period at Norfolk and Norwich University Hospital. We identified the incidence of skin reactions with lenalidomide, the dose of lenalidomide the at the time of the skin reaction, concomitant use of anti-myeloma medication (such as ixazomib) and other medications which could result in drug interactions or polypharmacy. **Results:** Of the 279 patients receiving lenalidomide, 54 patients (19%) developed a rash during their treatment. The median time for the rash to appear after initiation of treatment was 14 days (range 3 days and 365 days). 15 patients (5%) participated in the quadruple therapy trial; out of which, 4 patients developed a skin rash. Furthermore, 3 patients (1%) participated in the triple therapy trial – interestingly, all 3 patients developed a rash. Of the 54 patients who developed a rash, lenalidomide was stopped in 20 patients; the discontinuation of treatment resulted in complete resolution of the rash. Lenalidomide was reintroduced to 7 patients (13%) and was subsequently stopped in 4 patients. The dose was reduced to 15mg from 25mg in 3 patients – these patients were continued on 15mg with no further incidences of a rash. However, when lenalidomide was reintroduced at a lower dose (15mg and 10mg) for 2 patients, they developed rash and treatment was discontinued. **Conclusions:** In conclusion, 19% of patients who received lenalidomide treatment developed a rash. A study by Nardone et al found that the overall incidence of all-grade and high-grade rash was 27.2%.[4] There was 100% resolution of symptoms when lenalidomide was stopped. With the increase in lenalidomide in multiple myeloma treatment, it is imperative that clinicians monitor their patients for skin reactions.

Discovery of novel proteasome activators that enhance antigen presentation and trigger anti-myeloma T-cell immunity

James Driscoll[1], Priyanka Rana[2], James Ignatz-Hoover[2], Ehsan Malek[1]

[1]Case Western Reserve University; [2]University Hospitals

Introduction: Transformative advances in immunotherapy have revolutionized cancer treatment and induce durable clinical responses. However, only a small fraction of patients respond to immunotherapy and cancer cells escape immunosurveillance through molecular mechanisms that remain elusive. Proteasomes play a central role in immune surveillance mechanisms by generating peptides from intracellular proteins which are presented as antigens on the cell surface for recognition by CD8+ cytotoxic T lymphocytes (CTLs). Cancer cells employ strategies to downregulate antigen presentation and impair CTL-mediated tumor recognition and lysis. Recently, we discovered that HDAC6-specific inhibitors increased proteasome activity as well as the presentation of MHC class I antigens on tumor cells. However, current HDAC6 inhibitors have pharmacologic liabilities that limit efficacy, e.g., low potency and solubility, poor PK properties and potential genotoxicity. **Methods:** We performed a high-throughput, cell-based screen of 9,600 HDAC-specific compounds to identify novel molecular entities that increased proteasome activity in MM cells. Proteasomes degrade ovalbumin to generate the neoantigenic peptide "SIINFEKL", which is presented on the cell surface in complex with the MHC class I H-2Kb molecule and quantitated by flow cytometry. We identified and then tested a curated set of hits for the ability to increase antigen presentation on tumor cells. Finally, hits were evaluated for the ability to induce tumor lysis using T-cells engineered to express a T-cell receptor (TCR) that recognized SIINFEKL. **Results:** We identified hits that increased proteasomal activity by >50%. Importantly, two novel molecules identified in the screen increased proteasome activity more potently and more rapidly than the HDAC6-specific inhibitors with comparatively low cytotoxicity. Treatment of tumor cells with the novel compounds also increased levels of the MHC-class I-SIINFEKL complex more potently and rapidly than the HDAC6 inhibitors. MM cells were then co-cultured with CTLs genetically-engineered to express a SIINFEKL-restricted TCR. Pre-treatment of lymphoma or MM cells with novel compounds and HDAC6 inhibitors significantly increased tumor lysis by CTLs that expressed the SIINFEKL-restricted TCR. CTL-mediated tumor lysis was dramatically more potent compared to known HDAC6-specific inhibitors. **Conclusions:** Taken together, our results support the development of novel proteasome activators as a paradigm-shifting approach to enhance tumor antigenicity and boost CTL-mediated anti-tumor immunity. Proteasome activators represent a paradigm-shifting approach as cancer immunotherapeutics to overcome immune escape mechanisms and boost antitumor immunity. Moreover, our data provide compelling evidence to support the development of drugs that powerfully enhance proteasome proteolytic function as a therapeutic strategy to treat cancers and other disease-causing proteinopathies.

MM. These results have broader implications for enhancing current cancer treatments and advancing the field of nanomedicine.

Proteasome regulatory ATPase PSMC2 promotes drug resistance by mitigating ER stress and portends reduced overall survival in multiple myeloma

James Driscoll[1], James Ignatz-Hoover[2], Priyanka Rana[2], Ehsan Malek[1]

[1]Case Western Reserve University; [2]University Hospitals

Introduction: Multiple myeloma (MM) remains an incurable malignancy characterized by plasma cells that synthesize and secrete massive amounts of immunoglobulin (Ig, paraprotein). Hence, MM cells are exquisitely sensitive to agents that disrupt proteostasis. The proteasome is a highly sophisticated proteolytic complex designed to carry out selective hydrolysis of client proteins. Proteasome consist of two subcomplexes: a 20S catalytic core particle (CP) capped at one or both ends by 19S regulatory particle(s) (RP) that exhibit ATPase activity. Inhibition of the 20S proteasome catalytic subunit PSMB5 is the backbone of modern MM chemotherapy and has dramatically improved patient overall survival (OS). However, drug resistance inevitably emerges through molecular mechanisms that remain elusive. We postulated that the expression of clinically relevant proteasome subunits from MM cells correlated with reduced progression-free survival (PFS) and OS. **Methods:** We correlated the expression of proteasome genes with clinical outcomes using the APEX trial dataset, which compared the effect of bortezomib vs. steroid, and the MMRF COMMPASS trial. Identified genes were then overexpressed or knocked out in MM cell lines. Biological and biochemical assays were then performed to determine the effect on proteasome structure and localization, drug sensitivity and ER stress. **Results:** Results indicated that greater expression of the proteasome 19S RP ATPases PSMC2 and PSMC6 correlated with reduced OS, even outperforming the PI target PSMB5. MM cell lines that overexpressed PSMC2 and PSMC6 were then engineered. Non-denaturing gel electrophoresis demonstrated that PSMC2 is readily incorporated into 26S proteasomes. These cells exhibit higher levels of proteasome chymotrypsin-like activity activity (1.6-fold increase in ARH77 and 3-fold increase in U266 cells compared to controls; $p < 0.01$). PSMC2 overexpression induced resistant to PI challenge (bortezomib LD50 30 nM vs. 15nM in U266 cells and LD50 18 nM vs. 10 nM in ARH77 cells). PIs increase ER stress and PSMC2 overexpressing cells are better able to mitigate PI mediated ER stress with PSMC2 overexpressing cells exhibiting less induction of ER stress sensors phospho-IRE1α, ATF4, and phospho-PERK compared to PSMC2 KD cells. Mechanistically, PSMC subunits may function in as a key player in the localization of proteasomes to the ER, recognition and degradation of misfolded ER proteins, and ER-associated protein degradation. **Conclusions:** Taken together, our results demonstrate that PSMC2 and PSMC6 expression correlates with reduced OS in MM patients. Knockout of PSMC subunits decreased proteasome activity and increased dependence on autophagy, while PSMC upregulation increased proteasome activity and decreased PI sensitivity. Our work highlights the complex interplay of proteasome subunits in MM biology and suggests a prognostic and therapeutic role for 19S RP subunits in the anti-myeloma armamentarium.

Therapeutically targeting 19S proteasome-associated subunit PSMD1/Rpn2 in multiple myeloma

Ting Du[1], Xueping Wan[1], Arghya Ray[1], Sindhu Pillai[1], Ruben Carrasco[1], Nikhil Munshi[2], Dharminder Chauhan[1], Kenneth Anderson[3]

[1]Dana-Farber Cancer Institute; [2]Dana-Farber Cancer Institute, Boston, MA, USA, Veterans Affairs Boston Healthcare System/ Harvard Medical School; [3]LeBow Institute for Myeloma Therapeutics and Jerome Lipper Center for Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts

Introduction: Therapeutic targeting of 20S proteasomal catalytic activities has proven successful treatment for multiple myeloma (MM) patients; however, most patients eventually develop resistance to proteasome inhibitors (PIs). The 26S proteosome is composed of 1) 20S core particle (CP) which harbor protein-degradative proteolytic activities, and 2) 19S regulatory particle (RP) whose function is to recognize, and deubiquitinate ubiquitinated proteins substrates and allow for their entry into the 20S CP for degradation. PIs block the catalytic activities of 20S proteasome resulting in accumulation of ubiquitinated proteins thereby triggering intracellular toxicity. Aberrations in PIs binding to their active sites in 20S CP may cause PI-resistance. We hypothesized whether proteasome-driven protein degradation may be as effectively inhibited at the level of 19S RP as for 20S CP and this may prevent development of PI-resistance. Here, we utilized our preclinical in vitro and in vivo models to show that targeting a 19S RP component PSMD1/Rpn2 triggers anti-MM activity and overcomes PI-resistance. **Methods:** Cell viability was determined by CellTiter-Glo Luminescent assays (Promega Corporation). Apoptosis was measured using Annexin/PI staining (Biolegend). MM cells were transiently transfected with Rpn2 siRNA using the Nucleofector Kit V. Dox-inducible Rpn2-KD MM cell line was generated using shRNA. In vivo studies were performed using a human MM xenograft model. Statistical significance was assessed with Student's t test. **Results:** 1) Immunoblot analysis showed higher Rpn2 expression in MM vs normal peripheral blood mononuclear cells. 2) Immunohistochemistry studies showed higher Rpn2 expression in BM biopsies from MM patients than from healthy individuals. 3) DepMap analysis showed that Rpn2 was essential for MM cell lines. 4) Knocking down (KD) Rpn2 using transiently transfected siRNA decreased the viability of various MM cell lines, including those that are PI-resistant (ANBL6.BR) or carry p53 alterations (JJN3, ARP1) ($p < 0.01$). 5) Transfection with Rpn2-WT rescued cells from the growth-inhibitory activity of Rpn2-siRNA. 6) Dox-inducible CRISPR/Cas9 stable Rpn2-KD and -KO MM cells reduced cell growth. 7) Mechanistically, Rpn2 blockade both inhibited proteasome-mediated protein degradation, evident by increased ubiquitinated proteins levels, and triggered cell death/apoptosis associated with the activation of caspases, and endoplasmic reticulum stress response signaling. 8) Proteomic analysis showed decreased cell-cycle- and DNA replication-related pathway proteins in Rpn2 KD vs Rpn2 -WT cells. Finally, 9) Using Dox-inducible Rpn2-KD AMO1 MM cells in a xenograft mouse model, we found that Rpn2 depletion reduced tumor growth and

We postulated that the expression of clinically relevant proteasome subunits from MM cells correlated with reduced progression-free survival (PFS) and OS. **Methods:** We correlated the expression of proteasome genes with clinical outcomes using the APEX trial dataset, which compared the effect of bortezomib vs. steroid, and the MMRF COMMPASS trial. Identified genes were then overexpressed or knocked out in MM cell lines. Biological and biochemical assays were then performed to determine the effect on proteasome structure and localization, drug sensitivity and ER stress. **Results:** Results indicated that greater expression of the proteasome 19S RP ATPases PSMC2 and PSMC6 correlated with reduced OS, even outperforming the PI target PSMB5. MM cell lines that overexpressed PSMC2 and PSMC6 were then engineered. Non-denaturing gel electrophoresis demonstrated that PSMC2 is readily incorporated into 26S proteasomes. These cells exhibit higher levels of proteasome chymotrypsin-like activity activity (1.6-fold increase in ARH77 and 3-fold increase in U266 cells compared to controls; $p < 0.01$). PSMC2 overexpression induced resistant to PI challenge (bortezomib LD50 30 nM vs. 15nM in U266 cells and LD50 18 nM vs. 10 nM in ARH77 cells). PIs increase ER stress and PSMC2 overexpressing cells are better able to mitigate PI mediated ER stress with PSMC2 overexpressing cells exhibiting less induction of ER stress sensors phospho-IRE1α, ATF4, and phospho-PERK compared to PSMC2 KD cells. Mechanistically, PSMC subunits may function in as a key player in the localization of proteasomes to the ER, recognition and degradation of misfolded ER proteins, and ER-associated protein degradation. **Conclusions:** Taken together, our results demonstrate that PSMC2 and PSMC6 expression correlates with reduced OS in MM patients. Knockout of PSMC subunits decreased proteasome activity and increased dependence on autophagy, while PSMC upregulation increased proteasome activity and decreased PI sensitivity. Our work highlights the complex interplay of proteasome subunits in MM biology and suggests a prognostic and therapeutic role for 19S RP subunits in the anti-myeloma armamentarium.

Introduction: Therapeutic targeting of 20S proteasomal catalytic activities has proven successful treatment for multiple myeloma (MM) patients; however, most patients eventually develop resistance to proteasome inhibitors (PIs). The 26S proteosome is composed of 1) 20S core particle (CP) which harbor protein-degradative proteolytic activities, and 2) 19S regulatory particle (RP) whose function is to recognize, and deubiquitinate ubiquitinated proteins substrates and allow for their entry into the 20S CP for degradation. PIs block the catalytic activities of 20S proteasome resulting in accumulation of ubiquitinated proteins thereby triggering intracellular toxicity. Aberrations in PIs binding to their active sites in 20S CP may cause PI-resistance. We hypothesized whether proteasome-driven protein degradation may be as effectively inhibited at the level of 19S RP as for 20S CP and this may prevent development of PI-resistance. Here, we utilized our preclinical in vitro and in vivo models to show that targeting a 19S RP component PSMD1/Rpn2 triggers anti-MM activity and overcomes PI-resistance. **Methods:** Cell viability was determined by CellTiter-Glo Luminescent assays (Promega Corporation). Apoptosis was measured using Annexin/PI staining (Biolegend). MM cells were transiently transfected with Rpn2 siRNA using the Nucleofector Kit V. Dox-inducible Rpn2-KD MM cell line was generated using shRNA. In vivo studies were performed using a human MM xenograft model. Statistical significance was assessed with Student's t test. **Results:** 1) Immunoblot analysis showed higher Rpn2 expression in MM vs normal peripheral blood mononuclear cells. 2) Immunohistochemistry studies showed higher Rpn2 expression in BM biopsies from MM patients than from healthy individuals. 3) DepMap analysis showed that Rpn2 was essential for MM cell lines. 4) Knocking down (KD) Rpn2 using transiently transfected siRNA decreased the viability of various MM cell lines, including those that are PI-resistant (ANBL6.BR) or carry p53 alterations (JJN3, ARP1) ($p < 0.01$). 5) Transfection with Rpn2-WT rescued cells from the growth-inhibitory activity of Rpn2-siRNA. 6) Dox-inducible CRISPR/Cas9 stable Rpn2-KD and -KO MM cells reduced cell growth. 7) Mechanistically, Rpn2 blockade both inhibited proteasome-mediated protein degradation, evident by increased ubiquitinated proteins levels, and triggered cell death/apoptosis associated with the activation of caspases, and endoplasmic reticulum stress response signaling. 8) Proteomic analysis showed decreased cell-cycle- and DNA replication-related pathway proteins in Rpn2 KD vs Rpn2 -WT cells. Finally, 9) Using Dox-inducible Rpn2-KD AMO1 MM cells in a xenograft mouse model, we found that Rpn2 depletion reduced tumor growth and

prolonged mouse survival ($p < 0.005$). **Conclusions:** Our preclinical data demonstrate the therapeutic potential of targeting Rpn2 and provide the preclinical basis for developing Rpn2 inhibitors to overcome PI resistance in MM.

Introduction: The evolution of Multiple Myeloma (MM), a plasma cell (PC) disorder, is driven by the accumulation of genomic abnormalities that lead to cell cycle dysregulation, and is therefore associated with replication stress. PCs are antibody-secreting cells associated with a high transcriptional stress. Transcription/Replication Conflicts (TRCs) arising from collisions between the replication and transcription machineries can promote tumor progression but can also represent an Achille's heel to cancer cells. Here, we investigated the therapeutic interest of increasing TRCs to target specifically malignant PCs using a G-quadruplex-stabilizing small molecule. **Methods:** The prognostic value of 13 genes involved in TRC management was evaluated in three independent cohorts of MM patients and used to build the TRC score. The G-quadruplex (G4) stabilizer Pyridostatin (PDS) was used as a strategy to increase TRCs. The response of 18 Human Myeloma Cell Lines (HMCLs) to PDS was evaluated with proliferation assay. DNA damage response was investigated using western-blot and immunofluorescence detection of γH2AX and 53BP1. The cytotoxic effect of PDS on primary cells from MM patients was determined using the co-culture of MM cells with bone-marrow microenvironment cells and flow cytometry. **Results:** A signature of genes involved in TRCs management was found overexpressed in malignant PCs compared to normal PCs, suggesting that they adapted to an elevated replication stress through the upregulation of a TRC-resolving machinery. Combining those genes into a TRC score identified high risk MM patients that could benefit from a TRCs-increasing therapy. Treatment with PDS was associated with significant toxicity in 13 HMCLs with an IC50 ≤ 4 μM whereas 5 cell lines demonstrated higher resistance to PDS. It was associated with cell cycle arrest in G2/M, DNA damage and apoptosis. Importantly, primary myeloma cells were more sensitive to PDS treatment than the normal cells of the bone marrow micro-environment. PDS was able to improve the efficacy of current MM treatments. Firstly, PDS synergized with Melphalan leading to increased DNA damage, cell cycle arrest and apoptosis. Secondly, HMCLs and primary MM cells with a high TRC score were more sensitive to Panobinostat, and increasing R-loop formation with Panobinostat and stabilizing these R-loops with PDS had a synergistic effect in HMCLs as well as on primary MM cells. Thirdly, PDS-treated HMCLs were associated with cGAS-STING pathway activation, and a high TRC score was associated with early relapse in a cohort of MM patients treated with the monoclonal antibody Daratumumab, suggesting that these patients could benefit from a TRCs-increasing strategy. **Conclusions:** TRCs represent an actionable Achille's heel for malignant PCs that could be targeted by new therapies such as G4 stabilizers, to improve the efficacy of current MM treatments and the outcome of myeloma patients.

Introduction: Multiple myeloma (MM) remains incurable despite the availability of various therapies due to high rates of relapse and recurrence. Previous studies have highlighted the effectiveness of indirubin-3-monoxime (I3MO) as a proteasome inhibitor against MM cell proteasome activity. Histone deacetylase 6 (HDAC6) inhibitors have also shown promise in inhibiting the aggresome-autophagy pathway. Here, a novel I3MO derivative 8b was synthesized by coupling an HDAC6 inhibitor with the I3MO structure. **Methods:** We investigated the anti-MM effects of 8b both in vivo and in vitro. Western blots, immunofluorescence, and proteasome activity assay were utilized to investigate the effects of 8b on MM cell proteasome activity, aggresome and autophagosome formation. Dual-luciferase reporter gene assay was performed to identify downstream targets of 8b treatment. We further explored the function of TRIM28, the target of 8b, through shRNA knock-down (KD) and over-expression (OE) experiments. ChIP-seq and IP-MS were examined to clarify the potential target of TRIM28. **Results:** The novel derivative 8b efficiently inhibited myeloma cell proliferation and induced apoptosis in a dose- and time-dependent manner. Treatment with 8b caused cell cycle arrest in the S phase. In vivo studies confirmed the anti-MM effects of 8b treatment. Furthermore, 8b decreased proteasome activity and inhibited the formation of aggresomes and autophagosomes. Combining 8b with bortezomib (BTZ) enhanced apoptosis in MM cells both in vitro

prolonged mouse survival ($p < 0.005$). **Conclusions:** Our preclinical data demonstrate the therapeutic potential of targeting Rpn2 and provide the preclinical basis for developing Rpn2 inhibitors to overcome PI resistance in MM.

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin 300020, China.; [2]Chinese Academy of Medical Sciences and Peking Union Medical College, National Clinical Research Center for Blood Diseases, State Key Laboratory of Experimental Hematology

Introduction: Multiple myeloma (MM) remains incurable despite the availability of various therapies due to high rates of relapse and recurrence. Previous studies have highlighted the effectiveness of indirubin-3-monoxime (I3MO) as a proteasome inhibitor against MM cell proteasome activity. Histone deacetylase 6 (HDAC6) inhibitors have also shown promise in inhibiting the aggresome-autophagy pathway. Here, a novel I3MO derivative 8b was synthesized by coupling an HDAC6 inhibitor with the I3MO structure. **Methods:** We investigated the anti-MM effects of 8b both in vivo and in vitro. Western blots, immunofluorescence, and proteasome activity assay were utilized to investigate the effects of 8b on MM cell proteasome activity, aggresome and autophagosome formation. Dual-luciferase reporter gene assay was performed to identify downstream targets of 8b treatment. We further explored the function of TRIM28, the target of 8b, through shRNA knock-down (KD) and over-expression (OE) experiments. ChIP-seq and IP-MS were examined to clarify the potential target of TRIM28. **Results:** The novel derivative 8b efficiently inhibited myeloma cell proliferation and induced apoptosis in a dose- and time-dependent manner. Treatment with 8b caused cell cycle arrest in the S phase. In vivo studies confirmed the anti-MM effects of 8b treatment. Furthermore, 8b decreased proteasome activity and inhibited the formation of aggresomes and autophagosomes. Combining 8b with bortezomib (BTZ) enhanced apoptosis in MM cells both in vitro

and in vivo. Mechanistically, the dual-luciferase reporter gene assay revealed that 8b treatment significantly down-regulated TRIM28 promoter activity, resulting in transcriptional repression of TRIM28. Bioinformatics analysis showed a positive correlation between the levels of TRIM28 and multiple proteasome subunit genes, including PSMB1 and PSMB2, in MM. ChIP-qPCR assay confirmed that TRIM28 directly bound to the promoter region of PSMB1 and PSMB2. Knock-down of TRIM28 led to decreased PSMB1 and PSMB2 expression and reduced proteasome activity, increasing MM cell sensitivity to proteasome inhibitors (PIs). Knockdown of TRIM28 also suppressed autophagosome formation, promoting sensitivity to PIs treatment in multiple MM cell lines. IP-MS and Co-IP demonstrated that TRIM28 interacts with 14-3-3ζ and mediates its ubiquitination and degradation. 14-3-3ζ is a well-known negative regulator of autophagy, and its degradation induced by TRIM28 activates autophagy in MM cells. **Conclusions:** Our study identified a novel indirubin derivative targeting proteasome and autophagy for treating myeloma. This represents a promising therapeutic approach that could assistant overcoming the PIs resistance in myeloma. Additionally, our study for the first time clarified the role of TRIM28 in MM pathogenesis, which should be considered as a potential therapeutic target for MM.

Potent pre-clinical activity of EP300/CBP bromodomain inhibitor CCS1477 in multiple myeloma

Kris Frese[1], Luciano Nicosia[2], Fabio Amaral[2], Oliver Sinclair[2], Neil Pegg[1], Will West[1], Tomasz Knurowski[1], Karen Clegg[1], Debbie Haynes[1], Emma Searle[2], James Cavet[2], Tim Somervaille[2]

[1]CellCentric Ltd; [2]Universtiy of Manchester

Introduction: CCS1477 (also known as inobrodib) is a potent and selective inhibitor of the bromodomains of EP300 and CBP, two homologous histone acetyltransferases with critical roles in cellular growth and differentiation. CCS1477 has demonstrated potent anti-tumour activity against a variety of solid and haematological malignancies. **Methods:** The in vitro activity of CCS1477 was assessed via cell viability assays in a panel of cell lines, including 12 human multiple myeloma cell lines. The in vivo efficacy of CCS1477 was assessed using a range of doses up to 20mg/kg daily in an OPM-2 human myeloma cell line NOD-SCID xenograft model. RNAseq was used to assess the transcriptional effects of CCS1477, and ChIPseq was used to identify drug-induced changes in EP300/CBP chromatin binding, H3K27 acetylation, and chromatin accessibility. **Results:** In preclinical analyses CCS1477 induces potent growth inhibition through inducing cell cycle arrest at low nanomolar concentrations (GI50< 100nM) in myeloma cell lines, including lenalidomide refractory lines. In vivo, there was dose-dependent inhibition of tumour growth, with high doses eliciting tumour regression and sustained inhibition of tumour growth for two weeks beyond the end of treatment. RNA sequencing revealed substantial down regulation of transcription factor genes including MYB, MYC, IRF4, E2F1 and FOXM1; and GSEA showed significant enrichment among down regulated genes of gene sets associated with both MYC and E2F targets, consistent with drug-induced proliferative arrest. ChIP sequencing showed that EP300 and CBP binding peaks affected by CCS1477 were predominantly distributed over transcription factor binding motifs for IRF, Runt, bHLH, bZIP and MYB/SANT factor classes, and that loss of EP300/CBP correlated with a corresponding decrease in H3K27Ac. CCS1477 treatment induced a localized but significant reduction of EP300/CBP recruitment to intronic FGFR3 sites; FGFR3 is placed under the control of the active IGH promoter in the intergenic t(4;14) in OPM-2 cells. By 48 hours, in keeping with CCS1477-induced inactivation of IRF4 (a critical regulator of plasma cell differentiation required for myeloma cell growth) there was extensive genome-wide redistribution of EP300 binding away from sites with IRF4 motifs, while sites with other motifs remained occupied. **Conclusions:** CCS1477 treatment rapidly alters EP300/CBP chromatin occupancy and subsequent gene expression programs, resulting in potent anti-tumour activity in multiple myeloma cells. These encouraging data provide a strong rationale for the ongoing phase I/IIa clinical trial investigating the safety and efficacy of CCS1477 in advanced haematological malignancies (NCT04068597), and provide mechanistic insight into the activity of CCS1477 against multiple myeloma.

Introduction: In multiple myeloma (MM), venetoclax represents the first example of personalized medicine, as it has meaningful clinical activity in patients harboring the t(11;14) translocation, which is present in 15% to 20% of the patient population. This subgroup of patients generally displays upregulated BCL-2 expression and a higher BCL-2/BCL-XL ratio. The Bellini study demonstrated that combination therapy of BH3-mimetic venetoclax with velcade improves progression-free survival (PFS) and response rates in this subgroup of MM patients. However, the overall survival in the arm with venetoclax was inferior. Part of the decrease in overall survival could be from more infections, but overall survival is also impacted by subsequent therapies. Here, we hypothesized that acquired resistance to venetoclax leads to a global resistance to subsequent

and in vivo. Mechanistically, the dual-luciferase reporter gene assay revealed that 8b treatment significantly down-regulated TRIM28 promoter activity, resulting in transcriptional repression of TRIM28. Bioinformatics analysis showed a positive correlation between the levels of TRIM28 and multiple proteasome subunit genes, including PSMB1 and PSMB2, in MM. ChIP-qPCR assay confirmed that TRIM28 directly bound to the promoter region of PSMB1 and PSMB2. Knock-down of TRIM28 led to decreased PSMB1 and PSMB2 expression and reduced proteasome activity, increasing MM cell sensitivity to proteasome inhibitors (PIs). Knockdown of TRIM28 also suppressed autophagosome formation, promoting sensitivity to PIs treatment in multiple MM cell lines. IP-MS and Co-IP demonstrated that TRIM28 interacts with 14-3-3ζ and mediates its ubiquitination and degradation. 14-3-3ζ is a well-known negative regulator of autophagy, and its degradation induced by TRIM28 activates autophagy in MM cells. **Conclusions:** Our study identified a novel indirubin derivative targeting proteasome and autophagy for treating myeloma. This represents a promising therapeutic approach that could assistant overcoming the PIs resistance in myeloma. Additionally, our study for the first time clarified the role of TRIM28 in MM pathogenesis, which should be considered as a potential therapeutic target for MM.

In vivo, there was dose-dependent inhibition of tumour growth, with high doses eliciting tumour regression and sustained inhibition of tumour growth for two weeks beyond the end of treatment. RNA sequencing revealed substantial down regulation of transcription factor genes including MYB, MYC, IRF4, E2F1 and FOXM1; and GSEA showed significant enrichment among down regulated genes of gene sets associated with both MYC and E2F targets, consistent with drug-induced proliferative arrest. ChIP sequencing showed that EP300 and CBP binding peaks affected by CCS1477 were predominantly distributed over transcription factor binding motifs for IRF, Runt, bHLH, bZIP and MYB/SANT factor classes, and that loss of EP300/CBP correlated with a corresponding decrease in H3K27Ac. CCS1477 treatment induced a localized but significant reduction of EP300/CBP recruitment to intronic FGFR3 sites; FGFR3 is placed under the control of the active IGH promoter in the intergenic t(4;14) in OPM-2 cells. By 48 hours, in keeping with CCS1477-induced inactivation of IRF4 (a critical regulator of plasma cell differentiation required for myeloma cell growth) there was extensive genome-wide redistribution of EP300 binding away from sites with IRF4 motifs, while sites with other motifs remained occupied. **Conclusions:** CCS1477 treatment rapidly alters EP300/CBP chromatin occupancy and subsequent gene expression programs, resulting in potent anti-tumour activity in multiple myeloma cells. These encouraging data provide a strong rationale for the ongoing phase I/IIa clinical trial investigating the safety and efficacy of CCS1477 in advanced haematological malignancies (NCT04068597), and provide mechanistic insight into the activity of CCS1477 against multiple myeloma.

Introduction: In multiple myeloma (MM), venetoclax represents the first example of personalized medicine, as it has meaningful clinical activity in patients harboring the t(11;14) translocation, which is present in 15% to 20% of the patient population. This subgroup of patients generally displays upregulated BCL-2 expression and a higher BCL-2/BCL-XL ratio. The Bellini study demonstrated that combination therapy of BH3-mimetic venetoclax with velcade improves progression-free survival (PFS) and response rates in this subgroup of MM patients. However, the overall survival in the arm with venetoclax was inferior. Part of the decrease in overall survival could be from more infections, but overall survival is also impacted by subsequent therapies. Here, we hypothesized that acquired resistance to venetoclax leads to a global resistance to subsequent

and in vivo. Mechanistically, the dual-luciferase reporter gene assay revealed that 8b treatment significantly down-regulated TRIM28 promoter activity, resulting in transcriptional repression of TRIM28. Bioinformatics analysis showed a positive correlation between the levels of TRIM28 and multiple proteasome subunit genes, including PSMB1 and PSMB2, in MM. ChIP-qPCR assay confirmed that TRIM28 directly bound to the promoter region of PSMB1 and PSMB2. Knock-down of TRIM28 led to decreased PSMB1 and PSMB2 expression and reduced proteasome activity, increasing MM cell sensitivity to proteasome inhibitors (PIs). Knockdown of TRIM28 also suppressed autophagosome formation, promoting sensitivity to PIs treatment in multiple MM cell lines. IP-MS and Co-IP demonstrated that TRIM28 interacts with 14-3-3ζ and mediates its ubiquitination and degradation. 14-3-3ζ is a well-known negative regulator of autophagy, and its degradation induced by TRIM28 activates autophagy in MM cells. **Conclusions:** Our study identified a novel indirubin derivative targeting proteasome and autophagy for treating myeloma. This represents a promising therapeutic approach that could assistant overcoming the PIs resistance in myeloma. Additionally, our study for the first time clarified the role of TRIM28 in MM pathogenesis, which should be considered as a potential therapeutic target for MM.

Introduction: CCS1477 (also known as inobrodib) is a potent and selective inhibitor of the bromodomains of EP300 and CBP, two homologous histone acetyltransferases with critical roles in cellular growth and differentiation. CCS1477 has demonstrated potent anti-tumour activity against a variety of solid and haematological malignancies. **Methods:** The in vitro activity of CCS1477 was assessed via cell viability assays in a panel of cell lines, including 12 human multiple myeloma cell lines. The in vivo efficacy of CCS1477 was assessed using a range of doses up to 20mg/kg daily in an OPM-2 human myeloma cell line NOD-SCID xenograft model. RNAseq was used to assess the transcriptional effects of CCS1477, and ChIPseq was used to identify drug-induced changes in EP300/CBP chromatin binding, H3K27 acetylation, and chromatin accessibility. **Results:** In preclinical analyses CCS1477 induces potent growth inhibition through inducing cell cycle arrest at low nanomolar concentrations (GI50< 100nM) in myeloma cell lines, including lenalidomide refractory lines. In vivo, there was dose-dependent inhibition of tumour growth, with high doses eliciting tumour regression and sustained inhibition of tumour growth for two weeks beyond the end of treatment. RNA sequencing revealed substantial down regulation of transcription factor genes including MYB, MYC, IRF4, E2F1 and FOXM1; and GSEA showed significant enrichment among down regulated genes of gene sets associated with both MYC and E2F targets, consistent with drug-induced proliferative arrest. ChIP sequencing showed that EP300 and CBP binding peaks affected by CCS1477 were predominantly distributed over transcription factor binding motifs for IRF, Runt, bHLH, bZIP and MYB/SANT factor classes, and that loss of EP300/CBP correlated with a corresponding decrease in H3K27Ac. CCS1477 treatment induced a localized but significant reduction of EP300/CBP recruitment to intronic FGFR3 sites; FGFR3 is placed under the control of the active IGH promoter in the intergenic t(4;14) in OPM-2 cells. By 48 hours, in keeping with CCS1477-induced inactivation of IRF4 (a critical regulator of plasma cell differentiation required for myeloma cell growth) there was extensive genome-wide redistribution of EP300 binding away from sites with IRF4 motifs, while sites with other motifs remained occupied. **Conclusions:** CCS1477 treatment rapidly alters EP300/CBP chromatin occupancy and subsequent gene expression programs, resulting in potent anti-tumour activity in multiple myeloma cells. These encouraging data provide a strong rationale for the ongoing phase I/IIa clinical trial investigating the safety and efficacy of CCS1477 in advanced haematological malignancies (NCT04068597), and provide mechanistic insight into the activity of CCS1477 against multiple myeloma.

Introduction: In multiple myeloma (MM), venetoclax represents the first example of personalized medicine, as it has meaningful clinical activity in patients harboring the t(11;14) translocation, which is present in 15% to 20% of the patient population. This subgroup of patients generally displays upregulated BCL-2 expression and a higher BCL-2/BCL-XL ratio. The Bellini study demonstrated that combination therapy of BH3-mimetic venetoclax with velcade improves progression-free survival (PFS) and response rates in this subgroup of MM patients. However, the overall survival in the arm with venetoclax was inferior. Part of the decrease in overall survival could be from more infections, but overall survival is also impacted by subsequent therapies. Here, we hypothesized that acquired resistance to venetoclax leads to a global resistance to subsequent

therapeutic interventions impacting outcome. **Methods:** To answer this question and delineate the mechanisms that contribute to the development of an acquired drug-tolerant/resistant phenotype, we exposed venetoclax-sensitive myeloma cells to high dose treatment and generated monoclonal drug-tolerant expanded persister (DTEP) clones with a three- to ten-fold increase in IC50 compared to the parental cells. These cells were subjected to an integrated analysis including WGS, RNA-seq and proteomics, as well as drug screening. **Results:** Parental and resistant cells showed no marked differences in mutational frequencies, including the absence of genomic alterations in the BCL-2 gene such as the Gly101Val BCL-2 mutation. Instead, these clones exhibited reduced mitochondrial priming and had increased protein expression of anti-apoptotic regulators, including MCL-1, BCL-XL, and BCL-W, resulting in the sequestration of the pro-apoptotic ligand BIM. Since these data suggested a functional substitution between anti-apoptotic BCL-2 family members, we next evaluated if MCL1 or BCL-XL represent a co-dependency in resistant cells that can be therapeutically targeted to overcome resistance. Simultaneous inhibition of MCL1 (via S63845) or BCL-XL (via A155463) and BCL2 (via venetoclax) increased BIM release and enhanced cell death in the resistant clones compared to single agents, with combination index (CI) values < 0.3 in all doses tested. We next evaluated if the altered mitochondrial priming observed in the resistant cells was also responsible for a broader resistance to anti-cancer agents. Indeed, we found that most targeted agents, regardless of the mechanism of action, demonstrated a reduced ability to induce cell death in venetoclax-resistant cells compared with parental cells, suggesting a broad resistance to anti-cancer agents due to general selection for reduced apoptotic signaling. **Conclusions:** In conclusion, we report that resistance to Venetoclax in in vitro models of MM evolves from the outgrowth of persister clones with a shift in mitochondrial dependency that confers broad resistance to all anti-tumor agents, including standard-of-care myeloma drugs.

Introduction: ImiDs resistance has been linked to Cereblon (CRBN), a crucial protein in Immunomodulatory Drugs' (ImiDs') activity. Our most recent research has demonstrated the possible predictive value of serum CRBN in MM patients. 1 Thus, the purpose of the presented study was to revise our findings from earlier research on the predictive significance of serum CRBN levels in MM patients treated with RD (lenalidomide-dexamethasone) and to study any correlations with disease activity thereafter. **Methods:** We studied 92 MM patients from RD initiation until last follow up or death; Medical records were reviewed after patients' informed consent was obtained, while clinical and laboratory characteristics were collected. The median age of patients was 70 years (56% men, 44% women). Ig type was IgG in 64%, IgA in 22%, light-chain in 11% and IgD or biclonal in 3%. Thirty percent of patients were staged ISS 1, 20% ISS 2 and 51% ISS 3. RD was administered in 1st line in 8% of patients, second in 37%, third in 26%, forth in 16% and in 5th to 9th line in 13%. CRBN serum measurements at the time of RD treatment (69 patients), best response (59 patients) and at relapse/refractoriness to Rd (54 patients) were analyzed. CRBN was measured by commercially available ELISA kit (cloud clone), according to the manufacturer's instructions. Subsequent treatment lines after lenalidomide as well as patients' best responses to them, were recorded. Median serum CRBN level at each time point (RD initiation, at best response and Relapse) was used as a cut-off point in survival analysis. Statistical analysis was performed using the SPSS v28.0. software. **Results:** Median levels of CRBN were 247 pg/ml (range, 0-9760) at RD initiation, at best response to RD 142.5 pg/ml (range, 0 -9944) and at Relapse 298 pg/ml (range, 0-9840). A statistically significant decrease on CRBN serum levels was observed at best response compared to RD initiation. (p=0.001). Seven-year survival was improved in patients with CRBN levels below median at the time of RD initiation (p=0,013), during best response (p=0,032) but not in relapse/refractory patients to Rd (p=0,357) and time to next treatment (p=0.121). Regarding the disease characteristics, CRBN serum levels correlated with increased bone marrow infiltration (≥60%). (p=0.05). Furthermore, high CRBN serum levels at RD initiation correlated with patients experiencing an early relapse(≤ 12 months). Although intriguing, these patients responded to RD (≥PR) rather well. (p=0.03). **Conclusions:** Our analysis on CRBN serum levels, revealed an extended 7-year survival of our patients with serum CRBN levels below median both at RD initiation and at best response. Early resistance to RD was correlated with CRBN serum levels in our patients and further study would be beneficial.

Novel antigens LMA and KMA are expressed on malignant bone marrow plasma cells from patients at all stages of multiple myeloma and in other plasma cell dyscrasias

David Gottlieb[1], Mary Sartor[1], Rosanne Dunn[2]

[1]Centre for Cancer Research, Westmead Institute for Medical Research, Sydney, NSW, Australia; [2]HaemaLogiX Pty Ltd, Woolloomooloo, NSW, Australia

Introduction: As confirmed by flow cytometry and immunohistochemistry, lambda myeloma antigen (LMA) and kappa myeloma antigen (KMA) are found on the surface of malignant plasma cells (PCs) in multiple myeloma (MM) and other plasma cell dyscrasia (PCD) patient bone marrow (BM) samples, on human myeloma cell lines, on occasional mononuclear cells in healthy tonsillar tissue and secondary mucosal lymphoid tissue; they are not present on normal B cells in BM. KappaMab (formerly MDX-1097) clinical trials have confirmed that normal leukocytes are not depleted by the antibody with no on-target

therapeutic interventions impacting outcome. **Methods:** To answer this question and delineate the mechanisms that contribute to the development of an acquired drug-tolerant/resistant phenotype, we exposed venetoclax-sensitive myeloma cells to high dose treatment and generated monoclonal drug-tolerant expanded persister (DTEP) clones with a three- to ten-fold increase in IC50 compared to the parental cells. These cells were subjected to an integrated analysis including WGS, RNA-seq and proteomics, as well as drug screening. **Results:** Parental and resistant cells showed no marked differences in mutational frequencies, including the absence of genomic alterations in the BCL-2 gene such as the Gly101Val BCL-2 mutation. Novel antigens LMA and KMA are expressed on malignant bone marrow plasma cells from patients at all stages of multiple myeloma and in other plasma cell dyscrasias

David Gottlieb[1], Mary Sartor[1], Rosanne Dunn[2]

[1]Centre for Cancer Research, Westmead Institute for Medical Research, Sydney, NSW, Australia; [2]HaemaLogiX Pty Ltd, Woolloomooloo, NSW, Australia

Introduction: As confirmed by flow cytometry and immunohistochemistry, lambda myeloma antigen (LMA) and kappa myeloma antigen (KMA) are found on the surface of malignant plasma cells (PCs) in multiple myeloma (MM) and other plasma cell dyscrasia (PCD) patient bone marrow (BM) samples, on human myeloma cell lines, on occasional mononuclear cells in healthy tonsillar tissue and secondary mucosal lymphoid tissue; they are not present on normal B cells in BM. KappaMab (formerly MDX-1097) clinical trials have confirmed that normal leukocytes are not depleted by the antibody with no on-target

off-tumour effects1-3, and preclinical KMA.CAR T cell data has confirmed the antibody specificity4. KappaMab (targeting KMA) and LambdaMab (targeting LMA) bind to unique conformational epitopes in the constant regions of these sphingomyelin-associated light chains. This updated analysis confirms increased antigen (Ag) density of LMA and KMA on PCs versus decreased or stable Ag density of BCMA in disease progression from MGUS to relapsed, refractory MM (RRMM). Also, KMA is consistently found on BM PCs from plasmacytoma patients and LMA is consistently found on BM PCs from AL-amyloidosis (AL) patients. **Methods:** Patient BM samples (κ=66 and λ=41) were analysed using multiparametric FCM immunophenotyping with APC labelled LambdaMab (10B3) and KappaMab Fab'2 fragments, CD38, CD138, CD269 (BCMA), CD319 (SLAM F7), CD56 and CD45 monoclonal antibodies. PCs were identified as previously described5 by initial gating using CD38 and CD138. LMA and KMA expression was compared with the other cell markers. Ag density was calculated using QuantiBrite beads in PE. **Results:** In MGUS and SMM samples, 79% (11 of 14) of λ-type expressed LMA and 63% (10 of 16) of κ-type expressed KMA. KMA was expressed in 75% (12 of 16) of λRRMM samples and LMA was expressed in 50% (2 of 4) of λRRMM samples. Co-expression of KMA and BCMA occurred in 62% (18 of 29) of newly diagnosed (ND)MM and 63% (10 of 16) of RRMM samples. Co-expression of LMA and BCMA occurred in 59% (10 of 17) of NDMM and 50% (2 of 4) of RRMM samples. Both KMA and LMA Ag densities were higher than BCMA in the RRMM population. In the plasmacytoma BM PCs (n=5) KMA was expressed in 100% and KMA and BCMA were co-expressed in 100%. In the LMA+ AL samples (n=6), LMA was expressed in 100% and LMA and BCMA were co-expressed in 50%. **Conclusions:** KMA or LMA are expressed on PCs at all stages of MM, and all plasmacytomas and AL patient samples. The increased Ag densities of both KMA and LMA compared to BCMA on RRMM BM PCs indicates antigen persistence on a treatment resistant clone. The combination of increased and persistent antigen density and the specificity of these therapeutic antibodies could provide a significant benefit in the treatment of myeloma and PCDs. **References:** 1. Introduction: Our initial characterization of the non-coding transcriptome identified long non-coding RNAs (lncRNAs) as key players in multiple myeloma (MM) pathobiology, with 14 lncRNA transcript signature being a strong predictor of progression-free survival. **Methods:** We performed a large CRISPR interference screen to evaluate lncRNA dependency in MM and identified LINC01410 as a top dependency in 3 MM cell lines (H929, KMS12BM, KMS11). **Results:** We further observed that LINC01410 was significantly overexpressed in MM patient cells compared to normal PC [P=0.047], with a slightly higher expression in the cytogenetic high-risk t(4;14) subgroup [t(4,14) vs other MM subgroups, [P=0.076], and higher expression was correlated with inferior overall survival in newly diagnosed MM patients [P=0.014]. We verified functional impact of LINC01410 using siRNA-mediated silencing in a larger panel of MM cell lines (n=9) covering all the genetic subtypes. We also used gapmer antisense oligonucleotides (ASO) in a subset of MM cells. Both methods found time-dependent inhibition of MM cell viability [P < 0.0001] after LINC01410 knockdown. In cell culture, LINC01410 knockdown caused a decline in the population of S-phase cells and induced apoptotic cell death, as shown by flow cytometer analysis after BrdU and Annexin-PI staining respectively. LINC01410 knockdown negatively impacted key MM cell survival pathways including cell cycle control, unfolded protein response (UPR) and oxidative stress response. Moreover, cell cycle-dependent cyclins, which are important in MM (i.e., CCND1, CCND2, CCND3), were downregulated at the RNA and protein level. To determine LINC01410's interaction partners, we used an RNA-protein pull down (RPPD) assay and found that, among others, three minichromosome maintenance proteins (MCM4, MCM5, MCM7) interacted with LINC01410, and this was confirmed by RNA immunoprecipitation using an anti-MCM5 antibody. These proteins are part of the MCM complex, which is a helicase important for DNA replication and mRNA transcription. Importantly, a Co-Immunoprecipitation of MCM5 subunit followed by Mass spectrometry analysis after LINC01410 knockdown showed the loss of interaction of MCM proteins with RNA polymerase 1 (POLR1), which transcribes ribosomal rRNA. MCM proteins have long been associated with the activity of RNA polymerase II. However, our results suggest a novel role of the MCM complex in the transcription of rRNA, mediated by LINC01410. **Conclusions:** In conclusion, we propose a model where, in MM, LINC01410 binds to the MCM complex to assist DNA replication and cell cycle progression, with a potential role also in the transcription of rRNA. These results suggest important role for LINC01410 in MM pathobiology and using small molecule inhibitors and/or Gapmers a potential therapeutic target.

off-tumour effects1-3, and preclinical KMA.CAR T cell data has confirmed the antibody specificity4. KappaMab (targeting KMA) and LambdaMab (targeting LMA) bind to unique conformational epitopes in the constant regions of these sphingomyelin-associated light chains. This updated analysis confirms increased antigen (Ag) density of LMA and KMA on PCs versus decreased or stable Ag density of BCMA in disease progression from MGUS to relapsed, refractory MM (RRMM). Also, KMA is consistently found on BM PCs from plasmacytoma patients and LMA is consistently found on BM PCs from AL-amyloidosis (AL) patients. **Methods:** Patient BM samples (κ=66 and λ=41) were analysed using multiparametric FCM immunophenotyping with APC labelled LambdaMab (10B3) and KappaMab Fab'2 fragments, CD38, CD138, CD269 (BCMA), CD319 (SLAM F7), CD56 and CD45 monoclonal antibodies. PCs were identified as previously described5 by initial gating using CD38 and CD138. LMA and KMA expression was compared with the other cell markers. Ag density was calculated using QuantiBrite beads in PE. **Results:** In MGUS and SMM samples, 79% (11 of 14) of λ-type expressed LMA and 63% (10 of 16) of κ-type expressed KMA. KMA was expressed in 75% (12 of 16) of λRRMM samples and LMA was expressed in 50% (2 of 4) of λRRMM samples. Co-expression of KMA and BCMA occurred in 62% (18 of 29) of newly diagnosed (ND)MM and 63% (10 of 16) of RRMM samples. Co-expression of LMA and BCMA occurred in 59% (10 of 17) of NDMM and 50% (2 of 4) of RRMM samples. Both KMA and LMA Ag densities were higher than BCMA in the RRMM population. In the plasmacytoma BM PCs (n=5) KMA was expressed in 100% and KMA and BCMA were co-expressed in 100%. In the LMA+ AL samples (n=6), LMA was expressed in 100% and LMA and BCMA were co-expressed in 50%. **Conclusions:** KMA or LMA are expressed on PCs at all stages of MM, and all plasmacytomas and AL patient samples. The increased Ag densities of both KMA and LMA compared to BCMA on RRMM BM PCs indicates antigen persistence on a treatment resistant clone. The combination of increased and persistent antigen density and the specificity of these therapeutic antibodies could provide a significant benefit in the treatment of myeloma and PCDs. **References:** 1. Introduction: Our initial characterization of the non-coding transcriptome identified long non-coding RNAs (lncRNAs) as key players in multiple myeloma (MM) pathobiology, with 14 lncRNA transcript signature being a strong predictor of progression-free survival. **Methods:** We performed a large CRISPR interference screen to evaluate lncRNA dependency in MM and identified LINC01410 as a top dependency in 3 MM cell lines (H929, KMS12BM, KMS11). **Results:** We further observed that LINC01410 was significantly overexpressed in MM patient cells compared to normal PC [P=0.047], with a slightly higher expression in the cytogenetic high-risk t(4;14) subgroup [t(4,14) vs other MM subgroups, [P=0.076], and higher expression was correlated with inferior overall survival in newly diagnosed MM patients [P=0.014]. We verified functional impact of LINC01410 using siRNA-mediated silencing in a larger panel of MM cell lines (n=9) covering all the genetic subtypes. We also used gapmer antisense oligonucleotides (ASO) in a subset of MM cells. Both methods found time-dependent inhibition of MM cell viability [P < 0.0001] after LINC01410 knockdown. In cell culture, LINC01410 knockdown caused a decline in the population of S-phase cells and induced apoptotic cell death, as shown by flow cytometer analysis after BrdU and Annexin-PI staining respectively. Introduction: The induction of immunogenic cell death (ICD) is a critical mechanism by which the proteasome inhibitor bortezomib stimulates an anti-multiple myeloma (MM) immune response. During ICD, the dying cancer cell releases danger signals, such as calreticulin (CRT), which attract dendritic cells (DCs) to phagocytose the dying cell and present its antigens to T cells. Cancer cells employ several strategies to prevent this, including interfering with the exposure of CRT on the cell surface. Such resistance mechanisms may underlie the relapse and poor clinical outcome observed in MM patients. **Methods:** To find resistance mechanisms, we overlapped the CRT interactome after ICD induction with transcriptomic data from the IFM/DFCI dataset (n=360) and found that GABARAP both interacted with CRT and was associated with worse clinical outcomes at low expression levels (p=0.0017). We observed a strong correlation between GABARAP protein levels and the intensity of CRT exposure after BTZ treatment in 10 MM cell lines (R2: 0.62). Consequently, GABARAP KO in 4 ICD-sensitive cell lines impaired the exposure of CRT, thus diminishing ICD, as assessed by MM cell phagocytosis by DCs and T cell activation both in vitro and in vivo in an immunocompetent model. ICD was restored by add-back experiments using recombinant CRT or GABARAP overexpression. **Results:** To confirm this mechanism is active in patients, we analyzed single-cell RNA-seq from 80 MM patients and found a positive correlation between the expression of GABARAP and the ICD signature. Interestingly, low intratumor expression of GABARAP was associated with a lower T cell infiltration both at the single-cell level and by IHC analysis of bone marrow patient samples (n=10). Importantly, this mechanism generalizes to all MM cells but is especially relevant for those carrying a high-risk deletion of the 17p chromosome, where the gene is located. Mechanistically, proteomic analysis, confocal and transmission electron microscopy showed that GABARAP loss significantly altered the morphology of the Golgi apparatus, causing alterations in the vesicular transport systems and autophagy. This effectively stopped CRT transport to the surface, thus hindering ICD. By combining BTZ with autophagy inducers, we could restore vesicular transport of CRT to the cell surface and the subsequent MM-cell phagocytosis by DCs. Importantly, we also found this mechanism to be relevant in other cancer types, such as lung cancer cells. **Conclusions:** We propose a model by which dying cancer cells become resistant to ICD when the autophagy regulator GABARAP is low. The autophagy defects then disrupt the Golgi apparatus's structure, which then cannot export CRT to the cell surface. Without CRT, the dying cell cannot trigger an immune response. Therefore, coupling an ICD inducer, like bortezomib, with an autophagy inducer, like rapamycin, may improve patient outcomes in a variety of cancers and, specifically, in MM, where del(17p) is common and leads to worse outcomes.

Impact of preferential codonic loss of arginine in multiple myeloma

Ritu Gupta[1], Gurvinder Kaur[1], Lingaraja Jena[1], Anil Gupta[1], Atul Basnal[1], Omdutt Sharma[1], Lalit Kumar[1], Atul Sharma[1]

[1]AIIMS, New Delhi

Introduction: Several nonsynonymous somatic mutations are known to occur in the genome of Multiple Myeloma (MM) that may lead to loss or gain of gene functions in the growing tumor. The somatic codonic changes translate to corresponding alternate amino acid substitutions, some of which may facilitate the oncogenic circuitry and thus impact disease progression or clinical outcomes. **Methods:** Codonic changes were identified in whole exomes of malignant plasma cells (PCs) obtained from 109 PCPD patients including 71 MM patients. Whole exome sequencing data (generated using Nextera Exome library prep kit) were analyzed with Illumina Dragen pipeline. Circulating arginine levels in blood plasma were measured with Abcam's L-Arginine assay kit. **Results:** A preferential net loss of arginine specific codons (CGG (73%) > CGC (66%) > CGA (47%) > CGT (35%) >AGG (32%) > AGA (22%)) was observed in MM exome. The circulating arginine levels measured in blood plasma of such patients were also significantly reduced (p=0.03). Arginine (R) is not only a key player in cell metabolism but also marks the conserved cleavage sites (such as RXXR↓R) of proprotein convertase enzyme Furin. Mutations involving arginine over furin cleavage sites were mapped and highlighted the functional involvement of different furin sensitive proteins across PCPD. For example, furin sensitive RNF43 and TG were mutated at their furin cleavage sites in MGUS, while TNC, ADAM22 IGSF10 were mutated in SMM and others like MMP15, SLC9A3 were found to be mutated in MM. Kaplan Meier curve analyses showed a significant correlation between no loss of arginine with inferior PFS (p=0.012). Plausibly, if there is no loss of arginine, its continued abundance would tend to favor tumor progression and thus inferior outcomes. Further, mutations in arginine at furin cleavage sites in neoplastic plasma cells were found to be significantly associated with shorter PFS in MM (p=0.011) and could have prognostic value. **Conclusions:** The main novel finding of this study is that there is a selective net loss of arginine codon usage in MM that may have

Tissue factor as a new target for CAR-NK cell immunotherapy of multiple myeloma

Ming Liu[1], Tiffany Hughes[1], Rulong Shen[1], Junan Li[1], Bei Liu[1], Don Benson[1], Zhiwei Hu[1]

[1]The Ohio State University

Introduction: Multiple myeloma (MM) is a bone marrow-resident hematological malignancy of plasma cells and the second most diagnosed blood cancer. Despite the development of myeloma-targeted immunotherapies, MM has remained largely incurable. It is well documented that a suppressive bone marrow tumor microenvironment (TME), including dysfunctional natural killer (NK) cells, can cause the failure of current immunotherapies such as immune checkpoint blockade therapy (ICBT). The objective of this research is to target tissue factor as a new MM target and test corresponding chimeric antigen receptor-modified NK (CAR-NK) cell therapy as a monotherapy and in combination therapy to overcome the suppressive TME to enhance ICBT efficacy in MM. **Methods:** To validate TF as a new target in MM, we examined its expression on human MM lines (U266.B1, MM.1S, OPM2 and IM9) using flow cytometry. To target TF for CAR-NK cell immunotherapy, we developed TF-targeted human CAR constructs, which are composed of human fVII light chain followed sequentially by a hinge region of human IgG1, CD28 transmembrane and cytoplasmic domains and then by the cytoplasmic domains of 4-1BB and CD3ζ (TF-CAR dimer). To test the in vivo efficacy of TF CAR-NK cells as a monotherapy, we generated subcutaneous xenograft mouse models of human MM (U266.B1) and treated the animals with TF CAR-NK cells and control NK cells. To test the efficacy of TF CAR-NK cells in a novel combination therapy with ICBT (anti-PD-1 antibody, Ab), we first generated human MM xenografts in immunodeficient NSG mice (to mimic the suppressive TME) and then treated the animals with TF CAR-NK cells and anti-PD-1 Ab, TF CAR-NK cells plus IgG isotype control and control NK cells plus IgG isotype control. Whole body weights were recorded and blood chemistry from terminal blood samples were assayed as part of safety studies. **Results:** We showed and verified tissue factor expression in all four examined human MM cell lines, of which U266.B1 has a relatively higher expression level. After verifying TF expression in MM lines, we showed that TF CAR-NK cells alone are effective and safe for the treatment of human MM in preclinical mouse models. Furthermore, we showed that TF CAR-NK cells are more effective in combination therapy with ICBT (anti-PD-1 Ab) than TF CAR-NK cell alone in preclinical mouse models. There was no significant difference in whole body weights and blood chemistry panels between treated and control animals, suggesting that TF CAR-NK cells are safe. **Conclusions:** This study established the proof of concept of targeting TF as a new target in CAR-NK immunotherapy for effective and safe treatment of MM as a monotherapy and in a novel combination therapy with ICBT and may warrant further preclinical study and potentially future investigation in MM patients.

Impact of blocking the CD47 axis on phagocytosis of myeloma cells treated with CD38 antibodies and proteasome inhibitors

Katja Klausz[1], Carina Lynn Gehlert[1], Steffen Krohn[2], Dorothee Winterberg[1], Marta Lustig[1], Ammelie Svea Boje[1], Lenka Besse[3], Andrej Besse[3], Christoph Driessen[3], Matthias Peipp[1], Martin Gramatzki[3]

[1]University Medical Center Schleswig-Holstein; [2]Division of Antibody-Based Immunotherapy; [3]Cantonal Hospital St. Gallen

Introduction: The implementation of CD38-targeting antibodies daratumumab and isatuximab into combination regimens including a proteasome inhibitor (PI) significantly improved outcome and prolonged survival of patients with multiple myeloma (MM). Although many patients benefit, especially relapsed/refractory MM patients (RRMM) still have a very poor prognosis. In order to improve myeloma therapy, recently a phase II trial for RRMM patients was initiated combining the CD47 blocking antibody magrolimab with daratumumab or PIs (NCT04892446). Binding of CD47 highly expressed on MM cells to SIRPalpha on myeloid cells provides a strong 'don't eat me' signal and diminishes phagocytosis of tumor cells and thus antibody-dependent cellular phagocytosis (ADCP) – a known mode of action of therapeutic CD38 antibodies. Thereby, blocking the CD47-SIRPalpha axis with a CD47 antibody may enhance phagocytosis and improve patients' outcome. **Methods:** To investigate whether blocking the CD47-SIRPa axis enhances ADCP of myeloma cells by CD38 antibodies with or without PI treatment, we generated a CD47-IgG2sigma antibody using the CD47 binding sequences of magrolimab and a silent Fc to prevent interactions with Fcg receptors (FcgR) on macrophages. Macrophages were generated from healthy donor monocytes by cultivation with M-CSF and were used at an effector-to-target cell ratio of 1:1 in real-time live cell imaging experiments. CD47-IgG2 was tested in combination with daratumumab and isatuximab, respectively, using various MM cell lines. Pre-treatment of MM cells with PIs was performed prior use in experiments. Expression levels of CD47 and CD38 were determined by quantitative flow cytometry. **Results:** All tested myeloma cell lines express high levels of CD38 and CD47 and macrophages were SIRP-α+ and FcgR+. Importantly, ADCP of MM cells induced by monoclonal antibodies daratumumab and isatuximab could be enhanced by addition of the CD47 blocking antibody. However, improvement in phagocytosis strongly differs between myeloma cell lines not correlating with CD38 and CD47 levels. Thus, indicating that phagocytosis is influenced by additional factors. Of note, although high CD38 and CD47 expression was found on some MM cell lines, e.g., RPMI-8226, no ADCP could be induced at all. Pre-treating these resistant cells with PIs also did not induce significant

an impact on PFS. A targeted deprivation of Arginine in the tumor microenvironment is a potential therapeutic modality under trials in certain cancers and could be deeply investigated in MM. Arginine substitutions affect furin cleavage of important proteins involved in myelomatogenesis and contribute to PFS. Identification of furin sensitive substrates in early precursor stages of MGUS/SMM may help unveil potential targets for early therapy/ early prognosis and warrant further studies in this direction.

Introduction: The implementation of CD38-targeting antibodies daratumumab and isatuximab into combination regimens including a proteasome inhibitor (PI) significantly improved outcome and prolonged survival of patients with multiple myeloma (MM). Although many patients benefit, especially relapsed/refractory MM patients (RRMM) still have a very poor prognosis. In order to improve myeloma therapy, recently a phase II trial for RRMM patients was initiated combining the CD47 blocking antibody magrolimab with daratumumab or PIs (NCT04892446). Binding of CD47 highly expressed on MM cells to SIRPalpha on myeloid cells provides a strong 'don't eat me' signal and diminishes phagocytosis of tumor cells and thus antibody-dependent cellular phagocytosis (ADCP) – a known mode of action of therapeutic CD38 antibodies. Thereby, blocking the CD47-SIRPalpha axis with a CD47 antibody may enhance phagocytosis and improve patients' outcome. **Methods:** To investigate whether blocking the CD47-SIRPa axis enhances ADCP of myeloma cells by CD38 antibodies with or without PI treatment, we generated a CD47-IgG2sigma antibody using the CD47 binding sequences of magrolimab and a silent Fc to prevent interactions with Fcg receptors (FcgR) on macrophages. Macrophages were generated from healthy donor monocytes by cultivation with M-CSF and were used at an effector-to-target cell ratio of 1:1 in real-time live cell imaging experiments. CD47-IgG2 was tested in combination with daratumumab and isatuximab, respectively, using various MM cell lines. Pre-treatment of MM cells with PIs was performed prior use in experiments. Expression levels of CD47 and CD38 were determined by quantitative flow cytometry. **Results:** All tested myeloma cell lines express high levels of CD38 and CD47 and macrophages were SIRP-α+ and FcgR+. Importantly, ADCP of MM cells induced by monoclonal antibodies daratumumab and isatuximab could be enhanced by addition of the CD47 blocking antibody. However, improvement in phagocytosis strongly differs between myeloma cell lines not correlating with CD38 and CD47 levels. Thus, indicating that phagocytosis is influenced by additional factors. Of note, although high CD38 and CD47 expression was found on some MM cell lines, e.g., RPMI-8226, no ADCP could be induced at all. Pre-treating these resistant cells with PIs also did not induce significant

an impact on PFS. A targeted deprivation of Arginine in the tumor microenvironment is a potential therapeutic modality under trials in certain cancers and could be deeply investigated in MM. Arginine substitutions affect furin cleavage of important proteins involved in myelomatogenesis and contribute to PFS. Identification of furin sensitive substrates in early precursor stages of MGUS/SMM may help unveil potential targets for early therapy/ early prognosis and warrant further studies in this direction.

Tissue factor as a new target for CAR-NK cell immunotherapy of multiple myeloma

Ming Liu[1], Tiffany Hughes[1], Rulong Shen[1], Junan Li[1], Bei Liu[1], Don Benson[1], Zhiwei Hu[1]

[1]The Ohio State University

Introduction: Multiple myeloma (MM) is a bone marrow-resident hematological malignancy of plasma cells and the second most diagnosed blood cancer. Despite the development of myeloma-targeted immunotherapies, MM has remained largely incurable. It is well documented that a suppressive bone marrow tumor microenvironment (TME), including dysfunctional natural killer (NK) cells, can cause the failure of current immunotherapies such as immune checkpoint blockade therapy (ICBT). The objective of this research is to target tissue factor as a new MM target and test corresponding chimeric antigen receptor-modified NK (CAR-NK) cell therapy as a monotherapy and in combination therapy to overcome the suppressive TME to enhance ICBT efficacy in MM. **Methods:** To validate TF as a new target in MM, we examined its expression on human MM lines (U266.B1, MM.1S, OPM2 and IM9) using flow cytometry. To target TF for CAR-NK cell immunotherapy, we developed TF-targeted human CAR constructs, which are composed of human fVII light chain followed sequentially by a hinge region of human IgG1, CD28 transmembrane and cytoplasmic domains and then by the cytoplasmic domains of 4-1BB and CD3ζ (TF-CAR dimer). To test the in vivo efficacy of TF CAR-NK cells as a monotherapy, we generated subcutaneous xenograft mouse models of human MM (U266.B1) and treated the animals with TF CAR-NK cells and control NK cells. To test the efficacy of TF CAR-NK cells in a novel combination therapy with ICBT (anti-PD-1 antibody, Ab), we first generated human MM xenografts in immunodeficient NSG mice (to mimic the suppressive TME) and then treated the animals with TF CAR-NK cells and anti-PD-1 Ab, TF CAR-NK cells plus IgG isotype control and control NK cells plus IgG isotype control. Whole body weights were recorded and blood chemistry from terminal blood samples were assayed as part of safety studies. **Results:** We showed and verified tissue factor expression in all four examined human MM cell lines, of which U266.B1 has a relatively higher expression level. After verifying TF expression in MM lines, we showed that TF CAR-NK cells alone are effective and safe for the treatment of human MM in preclinical mouse models. Furthermore, we showed that TF CAR-NK cells are more effective in combination therapy with ICBT (anti-PD-1 Ab) than TF CAR-NK cell alone in preclinical mouse models. There was no significant difference in whole body weights and blood chemistry panels between treated and control animals, suggesting that TF CAR-NK cells are safe. **Conclusions:** This study established the proof of concept of targeting TF as a new target in CAR-NK immunotherapy for effective and safe treatment of MM as a monotherapy and in a novel combination therapy with ICBT and may warrant further preclinical study and potentially future investigation in MM patients.

Impact of blocking the CD47 axis on phagocytosis of myeloma cells treated with CD38 antibodies and proteasome inhibitors

Katja Klausz[1], Carina Lynn Gehlert[1], Steffen Krohn[2], Dorothee Winterberg[1], Marta Lustig[1], Ammelie Svea Boje[1], Lenka Besse[3], Andrej Besse[3], Christoph Driessen[3], Matthias Peipp[1], Martin Gramatzki[3]

[1]University Medical Center Schleswig-Holstein; [2]Division of Antibody-Based Immunotherapy; [3]Cantonal Hospital St. Gallen

Introduction: The implementation of CD38-targeting antibodies daratumumab and isatuximab into combination regimens including a proteasome inhibitor (PI) significantly improved outcome and prolonged survival of patients with multiple myeloma (MM). Although many patients benefit, especially relapsed/refractory MM patients (RRMM) still have a very poor prognosis. In order to improve myeloma therapy, recently a phase II trial for RRMM patients was initiated combining the CD47 blocking antibody magrolimab with daratumumab or PIs (NCT04892446). Binding of CD47 highly expressed on MM cells to SIRPalpha on myeloid cells provides a strong 'don't eat me' signal and diminishes phagocytosis of tumor cells and thus antibody-dependent cellular phagocytosis (ADCP) – a known mode of action of therapeutic CD38 antibodies. Thereby, blocking the CD47-SIRPalpha axis with a CD47 antibody may enhance phagocytosis and improve patients' outcome. **Methods:** To investigate whether blocking the CD47-SIRPa axis enhances ADCP of myeloma cells by CD38 antibodies with or without PI treatment, we generated a CD47-IgG2sigma antibody using the CD47 binding sequences of magrolimab and a silent Fc to prevent interactions with Fcg receptors (FcgR) on macrophages. Macrophages were generated from healthy donor monocytes by cultivation with M-CSF and were used at an effector-to-target cell ratio of 1:1 in real-time live cell imaging experiments. CD47-IgG2 was tested in combination with daratumumab and isatuximab, respectively, using various MM cell lines. Pre-treatment of MM cells with PIs was performed prior use in experiments. Expression levels of CD47 and CD38 were determined by quantitative flow cytometry. **Results:** All tested myeloma cell lines express high levels of CD38 and CD47 and macrophages were SIRP-α+ and FcgR+. Importantly, ADCP of MM cells induced by monoclonal antibodies daratumumab and isatuximab could be enhanced by addition of the CD47 blocking antibody. However, improvement in phagocytosis strongly differs between myeloma cell lines not correlating with CD38 and CD47 levels. Thus, indicating that phagocytosis is influenced by additional factors. Of note, although high CD38 and CD47 expression was found on some MM cell lines, e.g., RPMI-8226, no ADCP could be induced at all. Pre-treating these resistant cells with PIs also did not induce significant

phagocytosis. In responsive MM cell lines, ADCP mediated by CD38 antibodies in combination with the CD47 blocking antibody was slightly, but not significantly enhanced by pre-treatment with carfilzomib. **Conclusions:** Our findings demonstrate that blocking the CD47-SIRPa axis with a CD47 blocking antibody can improve ADCP of myeloma cells by therapeutic antibodies targeting CD38 and that PI treatment may enhance phagocytosis. Interestingly, there might be also MM cells with particular phenotypes rendering them resistant to phagocytosis. Further investigating these factors may help to identify MM patients that benefit from CD47 blockade.

Novel antibodies identified by phage display induce direct myeloma cell death

Steffen Krohn[1], Carina Lynn Gehlert[2], Dorothee Winterberg[2], Ammelie Svea Boje[2], Monika Brüggemann[2], Katja Weisel[3], Martin Gramatzki[4], Matthias Peipp[2], Katja Klausz[2]

[1]Division of Antibody-Based Immunotherapy; [2]University Medical Center Schleswig-Holstein; [3]University Medical Center of Hamburg-Eppendorf, Hamburg, Germany; [4]Cantonal Hospital St. Gallen

Introduction: In recent years, a variety of antibody-based immunotherapies were approved for multiple myeloma (MM) treatment and substantially improved patients' outcome. Nonetheless, the vast majority of MM immunotherapeutics including bispecific and monoclonal antibodies, antibody-drug conjugates as well as chimeric antigen-receptor T cells are directed against a very limited number of antigens on myeloma cells, e.g., CD38, SLAMF-7 and B cell maturation antigen (BCMA). This enables the development of resistances and relapsed/refractory patients still represent a major challenge. Novel target structures on MM cells may open additional avenues to develop effective antibody-based immunotherapies. **Methods:** Therefore, we aimed to identify new antibodies targeting alternative antigens on myeloma cells by immunizing mice with patient-derived malignant plasma cells, enriching myeloma cell binders by phage display and analyzing the antibody repertoire by next-generation sequencing (NGS). Binding properties of monoclonal single-chain fragment variable (scFv) antibodies were initially tested by cellular ELISA, including Chinese hamster ovary (CHO) cells transfected with known myeloma antigens. For testing the modes of action of the most promising candidates, scFv-Fc fusion proteins were produced by transient transfection and purified by affinity chromatography. Direct anti-tumor effects were investigated by flow cytometry using plasma cell lines as well as freshly isolated tumor cells. **Results:** Immunization of mice with primary myeloma cells enabled the generation of an immune scFv antibody library from 1.9 million different B cell clones for MM antibody selection through phage display. Accompanied NGS analyses revealed successful enrichment of more than 218 promising candidates. Among 41 initially tested scFv antibodies evolving from different B cell clones, 9 showed strong binding to myeloma cells and only weak binding to healthy donor peripheral blood mononuclear cells. Analyses with transfected CHO cells expressing individual myeloma antigens revealed that the most promising candidates neither bound CD38, SLAMF-7, CD138, CD56, IL-6R, FGFR3 nor BCMA. Beside a novel CD38 and CD54 antibody, respectively, 7 antibodies targeting yet unknown antigens on MM cells were isolated. Two of these antibodies, #9 and #16, were capable to directly induce rapid homotypic aggregation of myeloma cells. Incubation with and without cross-linking of the antibodies on MM cell surface resulted in up to 70 % 7-AAD/Annexin V+ MM cells. **Conclusions:** Our results show that phage display and NGS provide an innovative way to develop new antibodies with therapeutic potential for MM immunotherapy. Further characterization of the antibodies and investigations to identify the respective antigens are on-going.

MAP4K2 inhibition reinforces sensitivity to iberdomide in RAS-mutated MM through a CRBN-independent mechanism

Shirong Li[1], Jing Fu[1], Guifen Liu[1], Huihui Ma[1], Markus Mapara[2], Christophe Marcireau[3], Suzanne Lentzsch[1]

[1]Columbia University Irving Medical Center, New York, NY, USA; [2]Columbia Center for Translational Immunology; [3]Sanofi

Introduction: MAP4K2 is predominantly and highly expressed in the germinal center of B cells. We have shown that MAP4K2 knockdown in K- or N-RAS mutated MM cells inhibits cell growth associated with the downregulation of IKZF1/3, BCL-6, and c-MYC (Blood, 2021; 137:1754). Since IKZF1 regulates IRF4 and c-MYC transcription in MM, we hypothesized that IKZF1 degradation is one of the major mechanisms mediating MAP4K2-knockdown-induced MM cell death. **Methods:** IKZF1 Q146H mutant, which abrogates E3 ligase cereblon (CRBN)-mediated IKZF1 degradation, was constructed by mutagenesis PCR. MM.1SRASmut cells were lentivirally transduced to overexpress IKZF1WT or IKZF1Q146H and treated by MAP4K2 inhibitor (TL4-12), lenalidomide, or iberdomide. IKZF1 degradation was detected by WB and MM growth inhibition by proliferation assay. To investigate the combined effects of Iberdomide with MAP4K2 silencing on MM tumor growth, we generated subcutaneous MM xenografts in NOD/SCID mice using the inducible MAP4K2 shRNA MM.1SRASmut cells. MAP4K2 silencing was induced by doxycycline diet after the tumor was established. **Results:** As expected, lenalidomide failed to induce IKZF1-degradation in IKZF1Q146H MM.1SRASmut cells, confirming that IMiDs-induced IKZF1 degradation is mediated by CRBN. In contrast, IKZF1Q146H did not protect MM.1SRASmut from MAP4K2 inhibitor TL4-12-induced IKZF1 downregulation. Proliferation assays confirmed that IKZF1Q146H MM.1S cells were resistant to LEN-induced cell growth inhibition but not to TL4-12, demonstrating that MAP4K2 inhibition causes IKZF1 degradation and cell growth inhibition through a mechanism different from that of lenalidomide. We further evaluated the effects of MAP4K2 silencing in IKZF1Q146H MM.1SRASmut cells. MAP4K2 knockdown resulted in significant inhibition of cell proliferation and increase of apoptotic cells in both IKZF1WT and IKZF1Q146H MM.1S. IKZF1WT or IKZF1Q146H were also overexpressed in IMiDs resistant (RPMI-8266RASmut) MM

phagocytosis. In responsive MM cell lines, ADCP mediated by CD38 antibodies in combination with the CD47 blocking antibody was slightly, but not significantly enhanced by pre-treatment with carfilzomib. **Conclusions:** Our findings demonstrate that blocking the CD47-SIRPa axis with a CD47 blocking antibody can improve ADCP of myeloma cells by therapeutic antibodies targeting CD38 and that PI treatment may enhance phagocytosis. Interestingly, there might be also MM cells with particular phenotypes rendering them resistant to phagocytosis. Further investigating these factors may help to identify MM patients that benefit from CD47 blockade.

MAP4K2 inhibition reinforces sensitivity to iberdomide in RAS-mutated MM through a CRBN-independent mechanism

Shirong Li[1], Jing Fu[1], Guifen Liu[1], Huihui Ma[1], Markus Mapara[2], Christophe Marcireau[3], Suzanne Lentzsch[1]

[1]Columbia University Irving Medical Center, New York, NY, USA; [2]Columbia Center for Translational Immunology; [3]Sanofi

Introduction: MAP4K2 is predominantly and highly expressed in the germinal center of B cells. We have shown that MAP4K2 knockdown in K- or N-RAS mutated MM cells inhibits cell growth associated with the downregulation of IKZF1/3, BCL-6, and c-MYC (Blood, 2021; 137:1754). Since IKZF1 regulates IRF4 and c-MYC transcription in MM, we hypothesized that IKZF1 degradation is one of the major mechanisms mediating MAP4K2-knockdown-induced MM cell death. **Methods:** IKZF1 Q146H mutant, which abrogates E3 ligase cereblon (CRBN)-mediated IKZF1 degradation, was constructed by mutagenesis PCR. MM.1SRASmut cells were lentivirally transduced to overexpress IKZF1WT or IKZF1Q146H and treated by MAP4K2 inhibitor (TL4-12), lenalidomide, or iberdomide. IKZF1 degradation was detected by WB and MM growth inhibition by proliferation assay. To investigate the combined effects of Iberdomide with MAP4K2 silencing on MM tumor growth, we generated subcutaneous MM xenografts in NOD/SCID mice using the inducible MAP4K2 shRNA MM.1SRASmut cells. MAP4K2 silencing was induced by doxycycline diet after the tumor was established. **Results:** As expected, lenalidomide failed to induce IKZF1-degradation in IKZF1Q146H MM.1SRASmut cells, confirming that IMiDs-induced IKZF1 degradation is mediated by CRBN. In contrast, IKZF1Q146H did not protect MM.1SRASmut from MAP4K2 inhibitor TL4-12-induced IKZF1 downregulation. Proliferation assays confirmed that IKZF1Q146H MM.1S cells were resistant to LEN-induced cell growth inhibition but not to TL4-12, demonstrating that MAP4K2 inhibition causes IKZF1 degradation and cell growth inhibition through a mechanism different from that of lenalidomide. We further evaluated the effects of MAP4K2 silencing in IKZF1Q146H MM.1SRASmut cells. MAP4K2 knockdown resulted in significant inhibition of cell proliferation and increase of apoptotic cells in both IKZF1WT and IKZF1Q146H MM.1S. IKZF1WT or IKZF1Q146H were also overexpressed in IMiDs resistant (RPMI-8266RASmut) MM

cell line. MAP4K2 knockdown showed similar effects on IKZF1 degradation, cell proliferation, and apoptosis in IKZF1Q146H compared to IKZF1WT RPMI8266RASmut MM cells, confirming that MAP4K2 inhibition induces anti-MM effects by degrading IKZF1 via a CRBN independent mechanism and subsequently overcomes IMiDs resistance. Combination of iberdomide and MAP4K2-silencing led to synergistic in vitro anti-MM effects in RASMut MM cells. In our MM.1S xenograft mice model, combination of iberdomide with MAP4K2-silencing using a doxycycline-inducible shRNA approach further enhanced tumor inhibition and significantly prolonged mice survival compared to the single treatment. **Conclusions:** Combination of MAP4K2 inhibition with Iberdomide results in synergetic anti-cancer effects in lenalidomide-resistant MM. Our findings demonstrate that MAP4K2 is a novel therapeutic target to bypass IMiDs resistance in RAS-mutated MM. Therefore, this approach will provide a strategy to manage relapsed or refractory patients with multi-drug resistance and RAS-mutated MM.

Induction of pyroptosis for the treatment of multiple myeloma

Xinliang Mao[1], Yuanming He[1], Shuoyi Jiang[1], Zhenqian Huang[1]

[1]Guangzhou Medical University

Introduction: Pyroptosis is a novel type of cell death and induction of pyroptosis by small molecule chemicals has been proven to be a promising strategy for the treatment of hematologic malignancies, including acute myeloid leukemia (Johnson DC et al., Nat Med, 2018). However, little is known about myeloma cell pyroptosis. We recently found that proteasome inhibitors, the most important class of the mainstay anti-myeloma agents, trigger pyroptosis in a BAX and GSDME-dependent manner (Liang J et al., Acta Pharmacol Sin, 2023). Gasdermins are the executor of pyroptosis but the detailed regulatory mechanism is not well known. Novel agents to induce MM cell pyroptosis remained discovered. **Methods:** We applied phase contrast microscopy and ELISA to evaluate myeloma cell pyroptosis; RNA dequencing was performed to find out associated genes involved in clioquinol (CLQ)-induced MM cell pyroptosis. Western blotting was performed to examine GSDME activation and associated protein changes. Immunoprecipitation/immunoblotting was performed to examine the interaction between BAX, GSDME and IFIT1/T3. MM-cell line-derived myeloma xenografts were established by injection s.c MM cel lines into nude mice. **Results:** In the present study, we found that Clioquinol (CLQ), an anti-parasitic drug that has been proven to leukemia and myeloma cell apoptosis and autophagy, could also induce myeloma cell pyroptosis, featured with appearance of balloon-like morphology, leakage of lactate dehydrogenase (LDH) and cytochrome C, in both MM cell lines and primary cells. Moreover, CLQ induces MM cell pyroptosis through Caspase-3-mediated cleavage of GSDME. To find out the underlying mechanism, we performed an RNA sequencing on CLQ-induced pyroptotic cells. The results showed that interferon-inducible genes including IFIT1 and IFIT3 were strikingly upregulated by CLQ. IFIT1/T3 was downregulated in both primary and MM cell lines and they could be induced by CLQ. However, neither IFIT1 nor IFIT3 could induce MM cell pyroptosis. In contrast, both IFIT1 and IFIT3 could significantly enhance GSDME activation induced by CLQ. We further found that IFIT1/T3 bound to GSDME and increased the mitochondrial distribution of N-GSDME. Furthermore, we found that BAX bound to N-GSDME that could be markedly increased by IFIT1/T3 and IFIT1/T3 facilitated the translocalization of N-GSDME to mitochondria in the presence of BAX. Lastly, we found that CLQ displayed synergistic effects in myeloma cell pyroptosis with venetoclax, a specific inhibitor of Bcl-2 and an activator of BAX. The combination of CLQ and venetoclax displayed potent anti-MM activity in vivo in association with the induction of IFIT1/T3 and MM cell pyroptosis. **Conclusions:** This study therefore not only illustrates IFIT1/T3 is a important factor to enhance CLQ-induced myeloma cell pyroptosis. We also show the potential application of CLQ/VEN in myeloma therapy.

SLAMF1-derived peptide P7N4-Pen as anti-myeloma treatment

Ingvild Mestvedt[1], Therese Standal[2], Maria Yurchenko[1], Terje Espevik[1], Kristine Misund[3], Hanne Hella[3], Tobias Slørdahl[4]

[1]Centre of Molecular Inflammation research, Department of Clinical and Molecular Medicine, Norwegian University of Science and Technology; [2]NTNU; [3]Department of Clinical and Molecular Medicine, Norwegian University of Science and Technology; [4]St.Olavs Hospital

Introduction: Multiple myeloma (MM) is one of the most common hematological cancers. Despite advances in treatment, most patients relapse, and MM is still considered an incurable disease. Thus, there is a need to identify new targets for treatment and new therapeutic approaches for the development of new drugs. In human macrophages it has been demonstrated that Signaling lymphocytic activation molecule family member 1 (SLAMF1) amplifies signaling downstream Toll-like receptor 4. A synthetic peptide derived from a motif of SLAMF1 (P7), strongly inhibits production of inflammatory cytokines initiated by Nuclear factor kappa B (NFκB) activation. A total of 41 different variants of the SLAMF1-derived peptide have been synthesized, differing in one amino acid from the original peptide P7. Because NFκB has been found to be constitutively active in MM, we hypothesized that SLAMF1-derived peptides could inhibit proliferation and survival of MM cells. **Methods:** Cytotoxic and cytostatic effects of SLAMF1-derived peptides alone, or in combination with melphalan were assessed in a panel of human MM cell lines, including sublines resistant to proteasome inhibitors, and primary MM human tumor cells (CD138-positive). Toxicity testing was evaluated in healthy peripheral blood mononuclear cells (PBMCs). Cell death was assessed by investigation of cell membrane integrity, co-treatment by pan-caspase-inhibitor, caspase-3 and PARP cleavage (apoptosis readout), and H2AX phosphorylation (DNA fragmentation). The effect on protein stability and phosphorylation state of key oncogenes in MM tumor cells was also evaluated by WB analysis in various settings. **Results:** Screening of 39 SLAMF1-

cell line. MAP4K2 knockdown showed similar effects on IKZF1 degradation, cell proliferation, and apoptosis in IKZF1Q146H compared to IKZF1WT RPMI8266RASmut MM cells, confirming that MAP4K2 inhibition induces anti-MM effects by degrading IKZF1 via a CRBN independent mechanism and subsequently overcomes IMiDs resistance. Combination of iberdomide and MAP4K2-silencing led to synergistic in vitro anti-MM effects in RASMut MM cells. In our MM.1S xenograft mice model, combination of iberdomide with MAP4K2-silencing using a doxycycline-inducible shRNA approach further enhanced tumor inhibition and significantly prolonged mice survival compared to the single treatment. **Conclusions:** Combination of MAP4K2 inhibition with Iberdomide results in synergetic anti-cancer effects in lenalidomide-resistant MM. Our findings demonstrate that MAP4K2 is a novel therapeutic target to bypass IMiDs resistance in RAS-mutated MM. Therefore, this approach will provide a strategy to manage relapsed or refractory patients with multi-drug resistance and RAS-mutated MM.

Induction of pyroptosis for the treatment of multiple myeloma

Xinliang Mao[1], Yuanming He[1], Shuoyi Jiang[1], Zhenqian Huang[1]

[1]Guangzhou Medical University

Introduction: Pyroptosis is a novel type of cell death and induction of pyroptosis by small molecule chemicals has been proven to be a promising strategy for the treatment of hematologic malignancies, including acute myeloid leukemia (Johnson DC et al., Nat Med, 2018). However, little is known about myeloma cell pyroptosis. We recently found that proteasome inhibitors, the most important class of the mainstay anti-myeloma agents, trigger pyroptosis in a BAX and GSDME-dependent manner (Liang J et al., Acta Pharmacol Sin, 2023). Gasdermins are the executor of pyroptosis but the detailed regulatory mechanism is not well known. Novel agents to induce MM cell pyroptosis remained discovered. **Methods:** We applied phase contrast microscopy and ELISA to evaluate myeloma cell pyroptosis; RNA dequencing was performed to find out associated genes involved in clioquinol (CLQ)-induced MM cell pyroptosis. Western blotting was performed to examine GSDME activation and associated protein changes. Immunoprecipitation/immunoblotting was performed to examine the interaction between BAX, GSDME and IFIT1/T3. MM-cell line-derived myeloma xenografts were established by injection s.c MM cel lines into nude mice. **Results:** In the present study, we found that Clioquinol (CLQ), an anti-parasitic drug that has been proven to leukemia and myeloma cell apoptosis and autophagy, could also induce myeloma cell pyroptosis, featured with appearance of balloon-like morphology, leakage of lactate dehydrogenase (LDH) and cytochrome C, in both MM cell lines and primary cells. Moreover, CLQ induces MM cell pyroptosis through Caspase-3-mediated cleavage of GSDME. To find out the underlying mechanism, we performed an RNA sequencing on CLQ-induced pyroptotic cells. The results showed that interferon-inducible genes including IFIT1 and IFIT3 were strikingly upregulated by CLQ. IFIT1/T3 was downregulated in both primary and MM cell lines and they could be induced by CLQ. However, neither IFIT1 nor IFIT3 could induce MM cell pyroptosis. In contrast, both IFIT1 and IFIT3 could significantly enhance GSDME activation induced by CLQ. We further found that IFIT1/T3 bound to GSDME and increased the mitochondrial distribution of N-GSDME. Furthermore, we found that BAX bound to N-GSDME that could be markedly increased by IFIT1/T3 and IFIT1/T3 facilitated the translocalization of N-GSDME to mitochondria in the presence of BAX. Lastly, we found that CLQ displayed synergistic effects in myeloma cell pyroptosis with venetoclax, a specific inhibitor of Bcl-2 and an activator of BAX. The combination of CLQ and venetoclax displayed potent anti-MM activity in vivo in association with the induction of IFIT1/T3 and MM cell pyroptosis. **Conclusions:** This study therefore not only illustrates IFIT1/T3 is a important factor to enhance CLQ-induced myeloma cell pyroptosis. We also show the potential application of CLQ/VEN in myeloma therapy.

SLAMF1-derived peptide P7N4-Pen as anti-myeloma treatment

Ingvild Mestvedt[1], Therese Standal[2], Maria Yurchenko[1], Terje Espevik[1], Kristine Misund[3], Hanne Hella[3], Tobias Slørdahl[4]

[1]Centre of Molecular Inflammation research, Department of Clinical and Molecular Medicine, Norwegian University of Science and Technology; [2]NTNU; [3]Department of Clinical and Molecular Medicine, Norwegian University of Science and Technology; [4]St.Olavs Hospital

Introduction: Multiple myeloma (MM) is one of the most common hematological cancers. Despite advances in treatment, most patients relapse, and MM is still considered an incurable disease. Thus, there is a need to identify new targets for treatment and new therapeutic approaches for the development of new drugs. In human macrophages it has been demonstrated that Signaling lymphocytic activation molecule family member 1 (SLAMF1) amplifies signaling downstream Toll-like receptor 4. A synthetic peptide derived from a motif of SLAMF1 (P7), strongly inhibits production of inflammatory cytokines initiated by Nuclear factor kappa B (NFκB) activation. A total of 41 different variants of the SLAMF1-derived peptide have been synthesized, differing in one amino acid from the original peptide P7. Because NFκB has been found to be constitutively active in MM, we hypothesized that SLAMF1-derived peptides could inhibit proliferation and survival of MM cells. **Methods:** Cytotoxic and cytostatic effects of SLAMF1-derived peptides alone, or in combination with melphalan were assessed in a panel of human MM cell lines, including sublines resistant to proteasome inhibitors, and primary MM human tumor cells (CD138-positive). Toxicity testing was evaluated in healthy peripheral blood mononuclear cells (PBMCs). Cell death was assessed by investigation of cell membrane integrity, co-treatment by pan-caspase-inhibitor, caspase-3 and PARP cleavage (apoptosis readout), and H2AX phosphorylation (DNA fragmentation). The effect on protein stability and phosphorylation state of key oncogenes in MM tumor cells was also evaluated by WB analysis in various settings. **Results:** Screening of 39 SLAMF1-

cell line. MAP4K2 knockdown showed similar effects on IKZF1 degradation, cell proliferation, and apoptosis in IKZF1Q146H compared to IKZF1WT RPMI8266RASmut MM cells, confirming that MAP4K2 inhibition induces anti-MM effects by degrading IKZF1 via a CRBN independent mechanism and subsequently overcomes IMiDs resistance. Combination of iberdomide and MAP4K2-silencing led to synergistic in vitro anti-MM effects in RASMut MM cells. In our MM.1S xenograft mice model, combination of iberdomide with MAP4K2-silencing using a doxycycline-inducible shRNA approach further enhanced tumor inhibition and significantly prolonged mice survival compared to the single treatment. **Conclusions:** Combination of MAP4K2 inhibition with Iberdomide results in synergetic anti-cancer effects in lenalidomide-resistant MM. Our findings demonstrate that MAP4K2 is a novel therapeutic target to bypass IMiDs resistance in RAS-mutated MM. Introduction: Multiple myeloma (MM) is one of the most common hematological cancers. Despite advances in treatment, most patients relapse, and MM is still considered an incurable disease. Thus, there is a need to identify new targets for treatment and new therapeutic approaches for the development of new drugs. In human macrophages it has been demonstrated that Signaling lymphocytic activation molecule family member 1 (SLAMF1) amplifies signaling downstream Toll-like receptor 4. A synthetic peptide derived from a motif of SLAMF1 (P7), strongly inhibits production of inflammatory cytokines initiated by Nuclear factor kappa B (NFκB) activation. A total of 41 different variants of the SLAMF1-derived peptide have been synthesized, differing in one amino acid from the original peptide P7. Because NFκB has been found to be constitutively active in MM, we hypothesized that SLAMF1-derived peptides could inhibit proliferation and survival of MM cells. **Methods:** Cytotoxic and cytostatic effects of SLAMF1-derived peptides alone, or in combination with melphalan were assessed in a panel of human MM cell lines, including sublines resistant to proteasome inhibitors, and primary MM human tumor cells (CD138-positive). Toxicity testing was evaluated in healthy peripheral blood mononuclear cells (PBMCs). Cell death was assessed by investigation of cell membrane integrity, co-treatment by pan-caspase-inhibitor, caspase-3 and PARP cleavage (apoptosis readout), and H2AX phosphorylation (DNA fragmentation). The effect on protein stability and phosphorylation state of key oncogenes in MM tumor cells was also evaluated by WB analysis in various settings. **Results:** Screening of 39 SLAMF1-

derived peptides; variants in a human MM cell line revealed several peptides with striking anti-cancer potential. One of these peptides, P7N4, linked to Penetratin for intracellular delivery (P7N4-Pen), was shown to efficiently inhibit the viability and proliferation of both IL-6 dependent (INA-6, ANBL-6, OH-2, IH-1, KJON) and IL-6 independent (U266, JJN3, AMO-1) human MM cell lines. Additionally, P7N4-Pen induced cell death of primary CD138+ tumor cells from patients with MM (obtained with patient consent and REC approval). At the same time, P7N4-Pen showed no toxicity towards human PBMCs from healthy donors. Further, P7N4-Pen strongly inhibited the viability of human MM cells resistant to proteasome inhibitors and showed resilient potential together with the alkylating drug melphalan. The latter allows for a marked dose-reduction of melphalan, which could have strong benefits for patients' well-being. At the protein level P7N4-Pen induces cleavage of caspase-3 and PARP, H2AX phosphorylation and reduced levels of pro-survival proteins such as c-Myc, β-catenin and IRF4. **Conclusions:** Altogether, with the ability to induce cell death and inhibit several central MM survival factors, P7N4-Pen is a promising novel drug-candidate for treatment of MM, which could be tested in the future as monotherapy or in combination with other drugs.

Rationale and design of three ongoing phase 1/2 trials of modakafusp alfa, an innate immunity enhancer, in patients with multiple myeloma: The innovate clinical development program

Hira Mian[1], Cyrille Touzeau[2], Sarah Holstein[3], Edwin Kingsley[4], Dan Vogl[5], Richard Zuniga[6], Kihyun Kim[7], Kaveri Suryanarayan[8], Shining Wang[8], Laura Thesillat-Versmee[8], Yuyin Liu[8], Tian Chen[8], Yefei Zhang[8], Xavier Parot[8], Hans Lee[9]

(TDCA), Lexington, MA, USA; [9]Department of Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Introduction: There is an unmet need for novel, targeted therapies for patients (pts) with multiple myeloma (MM), particularly those with prior exposure and/or refractoriness to multiple drugs. The first-in-class innate immunity enhancer, modakafusp alfa (moda), delivers attenuated interferon (IFN) specifically to immune and MM cells. IFN signaling activates innate and adaptive immune cells and induces direct anti-proliferative and apoptotic effects in MM cells. Moda is composed of two IFN-α2b molecules fused to an IgG4 monoclonal antibody (mAb), which binds to a unique epitope on CD38; the IgG4 backbone has limited effector function. In preclinical xenograft studies, moda demonstrated prolonged inhibition of tumor growth when combined with standard-of-care (SOC) agents, such as immunomodulatory drugs (IMiDs), proteasome inhibitors (PIs), and anti-CD38 mAbs. As moda and daratumumab (dara) do not bind to the same epitope, they may have complementary mechanisms of action; furthermore, moda has been shown to increase CD38 expression on immune and MM cells. **Methods:** In the phase 2 iinnovate-1 extension study (NCT03215030), pts are randomized to receive moda 120 mg or 240 mg every four weeks to define the single-agent dose with the optimal benefit/risk profile in pts with ≥3 prior lines of therapy (LoT) who are at least triple-class refractory (to an IMiD, a PI, and an anti-CD38 mAb). The primary endpoint is overall response rate (ORR). In the phase 1b, 3-group iinnovate-2 study (NCT05556616), the safety and tolerability of moda are investigated in combination with SOC agents in pts with newly diagnosed MM (group 1) or relapsed/refractory MM (groups 2 and 3; group 3 will follow on from group 2). In all 3 groups, moda is escalated/de-escalated as part of doublet or triplet therapy depending on the safety observed. In group 1, moda is combined with lenalidomide (len) as post-transplant maintenance therapy. In group 2, moda is given as part of a doublet with a PI or IMiD. In group 3, moda will be given as part of a triplet and the starting dose will be guided by data from group 2. The primary endpoint for all 3 groups is safety. In the phase 1/2a iinnovate-3 study (NCT05590377), the safety, tolerability, and preliminary efficacy of moda combined with dara are evaluated. Pts with ≥3 prior LoTs including an IMiD, a PI, and an anti-CD38 mAb (or triple-class refractory regardless of LoT) are being enrolled in the phase 1 dose escalation. For the phase 2a dose optimization, two dose levels from phase 1 will be further evaluated in pts who have received 1–3 prior LoTs and are len-refractory and sensitive (non-refractory) or naïve to anti-CD38 therapy. The primary endpoint is safety for phase 1, and ORR for phase 2a. **Conclusions:** The ongoing iinnovate-1-2-3 studies are assessing the optimal dose of moda as a single agent and as part of doublet and triplet combinations with SOC agents for different MM pt populations, including those with high unmet medical needs.

Targeting TENT5C-associated regulation of antibody synthesis against multiple myeloma

Enrico Milan[1], Massimo Resnati[2], Sara Pennacchio[2], Lisa Viviani[2], Tommaso Perini[3], Simone Cenci[3]

[1]Università Vita-Salute San Raffaele; [2]San Raffaele Scientific Institute; [3]IRCCS Ospedale San Raffaele

Introduction: TENT5C locus on chromosome 1p12 is mutated or deleted in up to 20% of myeloma (MM) patients, indicating a plasma cell (PC)-specific tumor suppressor activity. TENT5C is a non-canonical poly(A)polymerase that selectively polyadenylates and stabilizes mRNA encoding immunoglobulins (Igs) and endoplasmic reticulum (ER)-targeted proteins, thus promoting the proteomic reshaping occurring during B to PC differentiation and sustaining humoral immune responses. We have recently demonstrated that MM cells have an advantage in losing TENT5C to restrict Ig production saving energy for proliferation. In line, its re-expression in mutated MM lines boosts the secretory activity beyond sustainability,

derived peptides; variants in a human MM cell line revealed several peptides with striking anti-cancer potential. One of these peptides, P7N4, linked to Penetratin for intracellular delivery (P7N4-Pen), was shown to efficiently inhibit the viability and proliferation of both IL-6 dependent (INA-6, ANBL-6, OH-2, IH-1, KJON) and IL-6 independent (U266, JJN3, AMO-1) human MM cell lines. Targeting TENT5C-associated regulation of antibody synthesis against multiple myeloma

Enrico Milan[1], Massimo Resnati[2], Sara Pennacchio[2], Lisa Viviani[2], Tommaso Perini[3], Simone Cenci[3]

[1]Università Vita-Salute San Raffaele; [2]San Raffaele Scientific Institute; [3]IRCCS Ospedale San Raffaele

Introduction: TENT5C locus on chromosome 1p12 is mutated or deleted in up to 20% of myeloma (MM) patients, indicating a plasma cell (PC)-specific tumor suppressor activity. TENT5C is a non-canonical poly(A)polymerase that selectively polyadenylates and stabilizes mRNA encoding immunoglobulins (Igs) and endoplasmic reticulum (ER)-targeted proteins, thus promoting the proteomic reshaping occurring during B to PC differentiation and sustaining humoral immune responses. We have recently demonstrated that MM cells have an advantage in losing TENT5C to restrict Ig production saving energy for proliferation. In line, its re-expression in mutated MM lines boosts the secretory activity beyond sustainability,

inducing intracellular ATP shortage, ROS accumulation and reduced cell growth in vitro. Our goal is to challenge the effects of TENT5C manipulation in in vivo models of MM, and to dissect the precise molecular circuits coordinating intensive Ig synthesis in PCs to unveil new MM vulnerabilities. **Methods:** To dissect the molecular mechanisms involved in TENT5C oncosuppressive role in MM, we combined cutting-edge molecular biology, protein biochemistry and unbiased proteomics, and adopted in vivo models. **Results:** To assess the impact of TENT5C manipulation in vivo, we silenced or overexpressed the protein in AMLC-2 cells that bear a hemizygous loss in chromosome 1p. Following intravenous and subcutaneous injections of TENT5C-manipulated cells into Rag2–/– IL2rg–/– mice, we found remarkably reduced tumor growth and longer survival in recipients of TENT5C-overexpressing cells, despite higher initial circulating LC levels. This in vivo association of higher proliferation with drastically decreased secretory activity clearly reveals that the presence of TENT5C mutations uncouples monoclonal component levels from disease burden. In parallel, we disclosed that TENT5C promotes the presence of calreticulin and CD38 in the cell surface, with translational implications for immunotherapies. Finally, to clarify how TENT5C manages to orchestrate a global cellular reshaping towards secretion, we focused on the few TENT5C-modulated proteins not belonging to the secretory apparatus. Upon TENT5C overexpression, we found a specific induction of nucleolar methyltransferases of rRNAs and tRNAs, whose functions are to promote ribosome assembly and to improve the translation of rare codons. This suggests that TENT5C mRNA stabilizing activity is coordinated with mechanisms that optimize protein translation in order to harmonize intensive antibody synthesis with cellular homeostasis, thus revealing a potential novel Achille's heel of MM. **Conclusions:** Altogether, our data disclose an unexpected molecular network, centered on TENT5C, regulating the trade-off between Ig synthesis and cell growth that may be exploited to design new therapeutic strategies aiming at altering PC protein homeostasis, eliminating the pathogenic clone, and improving the efficacy of current therapeutic options.

Introduction: Single agent venetoclax (Ven) is effective only in a minority of MM, i.e. 40% of t(11;14)-MM, underscoring the need to better understand the basis of Ven efficacy. We previously reported that low electron transport chain (ETC) activity and reduced oxidative phosphorylation (OXPHOS) are predictive biomarkers of sensitivity to the BCL-2 antagonist, Ven in MM. Moreover, ETC blockade sensitized Ven-resistant MM. Given that heme plays a central role in regulating ETC activity, facilitating catalytic and electron transfer reactions, and regulating assembly of the respiratory complexes, we investigated the role of heme in regulating MM Ven sensitivity. **Methods:** Heme (iron protoporphyrin IX) quantification was performed using a fluorometric assay designed to measure the fluorescence of protoporphyrin IX upon the release of iron from heme. We employed a glass-based antibody array for broad-scope protein phosphorylation profiling of MM cell lines treated with hemin (oxidized heme). MM cell lines treated with heme biosynthesis, MEK/ERK and a panel of kinase and metabolic inhibitors were evaluated for viability by flow cytometry. **Results:** We recently showed that a more B-cell-like program was associated with Ven sensitivity, thus using the more B-cell like CD2 gene expression subtype for Ven sensitivity we compared the CD1 vs CD2 gene expression subgroups of MM from the CoMMpass trial. This analysis found the CD2 subgroup to exhibit reduced heme biosynthesis gene expression while exhibiting elevated levels of the heme exporters FLVCR1b and ABCG2. Correspondingly, we found Ven sensitive (VS) t(11;14) MM to exhibit i) reduced intracellular heme; ii) reduced rate-limiting ALAS1 enzyme expression and lastly; iii) reduced uptake of 5-aminolevulinic acid (5-ALA), the first committed heme biosynthesis precursor; in line with our previous reports showing VS MM exhibits reduced ETC activity. Supportive of reduced heme in t(11;14) correlating with Ven sensitivity, we observed hemin and protoporphyrin IX supplementation to reverse Ven sensitivity. Suppression of heme synthesis by inhibiting ALAS1 (the rate-limiting step in heme biosynthesis) or ferrochetalase (FECH, the last step in heme biosynthesis), with a newly developed FECH inhibitor promoted Ven sensitivity both in Ven-resistant MM cell lines and primary MM patient samples. Kinase profiling and pharmacological interrogation revealed the RAS-RAF-MEK axis and MCL-1 induction to regulate hemin-induced Ven resistance. **Conclusions:** Our results mechanistically illustrate a role for heme in modulating proximity to the apoptotic threshold with broader translational implications. Heme can be sourced from both extrinsic sources such as through diet and cells in the extrinsic milieu or through de novo synthesis, underscoring the importance of investigating heme metabolism in MM therapy.

Introduction: Relapsed/refractory (R/R) multiple myeloma (MM) patients have limited therapeutic options and poor outcome. A major limitation for the development of targeted therapies in this setting is the poor predictive value of preclinical models. In fact,

standard two-dimensional (2D) cultures do not recapitulate the complexity of the tumour microenvironment (TME) that has a crucial role in cancer progression and therapy response. This limitation most likely explains the massive failure of the approval rate of novel treatments from international medical agencies. Here we developed in vitro three-dimensional (3D) scaffolds with biomimetic tissue like properties and leveraged this platform for drug testing and for the identification of TME-mediated mechanisms of drug resistance in R/R MM. **Methods:** Bone marrow-like 3D scaffolds (BM3Ds) were obtained through a crosslinking and a freeze-drying process by combining collagen type I and hydroxyapatite (30:70 wt% ratio). Human Stromal (HS5), Human Umbilical Vein Endothelial Cells (HUVEC) and MM cell lines H929 or JJN3 were co-cultured in BM3Ds, imaged by confocal microscopy after immunofluorescence staining or embedded in paraffin for immunohistochemistry. Cells were treated with increasing concentrations of Bortezomib (BTZ) and Lenalidomide (LEN) to calculate the half maximal inhibitory concentration (IC50) by cell viability assays. **Results:** BM3Ds displayed a highly reproducible micro-architecture resembling clinical BM specimens and a tunable structure enabling applications in 96/wells format. HUVEC and HS5 widely colonized the inner space of the scaffold with a multilayer cell organization. Conversely, MM cell lines grouped between the collagen fibers supported by the layers of stroma and endothelium when in co-cultures. By comparing 2D and 3D conditions we observed no differences in the growth rate of MMs, while HUVEC and HS5 showed a decreased proliferation at 72 hours from seeding when cultured in BM3Ds ($P < 0.001$). In BM3Ds, H929 cells showed decreased IC50 to both LEN and BTZ (0.60 μM and 0.0009 μM) compared to 2D culture (1.58 μM and 0.0019 μM). JJN3 did not respond to LEN and showed a doubled IC50 when treated with BTZ in BM3Ds (0.002 μM) with respect to 2D culture (0.001 μM). Then we optimized a 5 days protocol for a standardized process of drug discovery/testing. Specifically, HUVEC and HS5 are seeded in BM3Ds (3×10^5/each) at day 0 followed by JJN3 or H929 (5×10^5) at day 3. Treatments are carried out at day 4 prior to the drug sensitivity evaluation at day 5. **Conclusions:** BM3Ds is an alternative biomimetic 3D approach to model R/R MM for preclinical drug screening and drug discovery application. Ongoing single cell RNASeq experiments of stromal, endothelium and MM cells co-cultured in 2D or in BM3Ds after BTZ and LEN treatment will inform on molecular pathways driving mechanisms of drug resistance. This platform is expected to increase the consistency of preclinical data and to foster the clinical translation of new discoveries.

Introduction: In most cases, multiple myeloma (MM) remains an incurable disease despite the survival improvement provided by current treatments. The persisting clinical challenge resides in its high ability to resist drugs as shown by the frequent relapses observed regardless of the treatment. Abnormal iron homeostasis is implicated in tumorigenesis and the progression of several cancers. Ironomycin is a small synthetic derivative of salinomycin that induces DNA damage and non-apoptotic cell death by sequestering iron in lysosomes. Preclinical studies in Acute Myeloid Leukemia and Diffuse Large B-Cell Lymphoma have revealed the therapeutic interest of ironomycin in treating hematological malignancies. Here, we evaluate the therapeutic interest of targeting iron homeostasis with ironomycin to target MM cells. **Methods:** The prognostic value of genes related to iron metabolism in cancer was evaluated in 4 independent MM cohorts and used to build the Iron Score (IS). Cytotoxic effect of ironomycin on primary cells from MM patients was evaluated by flow cytometry. The response of 9 HMCLs (Human Myeloma Cell Lines) to ironomycin was evaluated by Cell-Titer Glo (CTG). Three cell lines with different sensitivities were selected for further characterization. Metabolic and transcriptional changes induced by ironomycin in 3 HMCLs were evaluated by Seahorse assay, metabolomics analysis, and RNA-seq. The synergistic effects of the combination of ironomycin and immunomodulatory drugs (IMiDs), lenalidomide and pomalidomide, were determined by synergy matrixes using R package "SynergyFinder". **Results:** High iron score value predicts a poor outcome of MM patients in 4 independent cohorts. Ironomycin exerts cytotoxicity on HMCLs at nanomolar concentrations. Primary plasma cells from patients are more sensitive to ironomycin than other cell types from the microenvironment. Ironomycin reduces MM cells proliferation and viability, causes DNA damage and triggers caspase-dependent apoptosis. It also affects the expression of several oncogenes and causes epigenetic dysregulation. Ironomycin induces a metabolic shift from energetic to quiescent or glycolytic metabolism, together with an activation of the interferon response. Ironomycin synergizes with lenalidomide and pomalidomide to kill MM cells. Drug combination downregulates several oncogenes, increases DNA damage and interferon signaling, leading to apoptosis. **Conclusions:** Ironomycin causes significant cytotoxicity on MM cells mediated by DNA damage, interferon signaling activation and triggering of apoptosis. Targeting iron homeostasis with ironomycin is a new potential anti-myeloma strategy alone and in combination with IMiDs lenalidomide and pomalidomide.

standard two-dimensional (2D) cultures do not recapitulate the complexity of the tumour microenvironment (TME) that has a crucial role in cancer progression and therapy response. This limitation most likely explains the massive failure of the approval rate of novel treatments from international medical agencies. [1]Asl Roma 1; [2]Asl Pescara; [3]Clinica di Ematologia, Azienda Ospedaliero-Universitaria delle Marche, Ancona, Italy; [4]Campus Biomedico; [5]Sapienza; [6]Gemelli; [7]Ptv, Roma; [8]Asl Frosinone; [9]Gimema; [10]Asl Viterbo

Introduction: Patients with multiple myeloma are at higher risk for infections due to disease pathogenesis and administered therapies. Infection is a significant cause of morbidity and the leading cause of death in patients (pts) with newly diagnosed multiple myeloma (NDMM). The risk of infection may be associated with neutropenia, hypogammaglobulinemia, and NK cell depletion. Daratumumab is approved for NDMM or relapsed/refractory multiple myeloma (RRMM). The use of daratumumab (dara) has improved patient outcomes but has changed the frequency and epidemiology of infections. The overall risk of infection with daratumumab treatment is around 38%, being upper respiratory tract infections the most common.The purpose of this study was to evaluate the number, the type and risk of infection events (IE) associated with the use of dara in patients with NDMM in the induction phase of transplant eligible and transplant ineligible NDMM patients. **Methods:** We retrospectively evaluated 308 pts with NDMM treatment in 8 Italian Hematology Centers who underwent induction therapy based on dara-bortezomib, thalidomide and dexamethasone (D-VTD), dara-lenalidomide and dexamethasone (D-Rd) and dara-bortezomib and dexamethasone (D-VMP) between 2020 and 2023.. **Results:** Overall, 105/308 (34%) developed an infection of any grade, 30/105 in D-VTD, 61/105in D-Rd and 14/105 in D-VMP arm. There was no difference on antiviral and antimicrobial prophylaxis in the 3 treatment groups. The median time to infection events was similar between the 3 groups D-VMP 161 days (104-243), D-Rd 156 days (97-370) and D-VTD 82 days (44-184) (p=0.064). Type of IE were upper respiratory tract infection in 81/105 pts (77%), SARS-COV2 infection 12/105 pts (11%), herpes simplex and varicella zoster virus (VZV) in 2/105 pts (1.9%), abdominal infection 3/105 pts (2.8%) and infection of urinary tract 2/105 pts (1.9%) of any grade. No differences were present in the grade and in the duration of IE. In all groups a statistically significant reduction was seen in the IgA level at the time of the IE (p=0.006), while no differences were present for IgG and IgM level in 3 treatment group. Moreover, a significant difference in neutropenia (p=0.002) and lymphocytophenia pre and post IE (p=0.006) resulted in all three groups. In our experience, no significant differences were found between the three treatment groups in terms of incidence, type and degree of infections, while significant differences were found between baseline IgA levels, neutropenia and lymphopenia at the time of the IE. **Conclusions:** A larger patient cohort and further studies are warranted to confirm these data and to identify patients at higher risk for infection, understanding the potential benefit of infectious prophylaxis in the clinical management in this setting of NDMM.

Introduction: We showed that human stromal cells (HS5) treated with extracellular vesicles (EV) derived from plasma of myeloma (MM) patients (MM-EV) promoted adhesion of human MM cell lines (HMCL), with preliminary proteomic profiling of MM- vs healthy donors HD-EV revealing enrichment of factors implicated in cell migration and adhesion. Aims: demonstrate that MM-EV induce the formation of a tumor microenvironment (TME) favouring MM progression; identify the protein content of MM-EV promoting this; discover signaling drivers of EV-mediated functional remodelling of HS5 towards a pre-metastatic phenotype. **Methods:** EV were enriched from 1mL plasma using a commercial kit. We performed: proteomic profiling of EV [x10 HD, x8 MM, x4 asymptomatic MM, x10 premalignant stage MGUS]; phosphoproteomic profiling and gene expression analysis (RNA sequencing) of HS5 cells pre-treated with MM- vs HD/MGUS-EV; in vitro (co-cultures) and in vivo (NSG MM-bearing mice) studies. **Results:** HS5 cells treated with MM-EV induced HMCL proliferation (p =.0026) and drug resistance (p =.0013) to anti-MM drugs when compared to untreated HS5-cells. Preconditioning mice with MM-EV significantly enhanced tumour growth vs control mice. Importantly, a higher number of disseminated HMCL was observed in liver, kidneys, heart in the preconditioned mice, indicating an augmented (extramedullary) metastatic potential. 412 proteins were quantified by proteomic profiling of EV with 8/13 corresponding to universal cancer EV markers. Gene ontology analysis of identified proteins (G:Profiler; p <.05) revealed enrichment for cellular component terms, eg "extracellular vesicles/exosomes", and for biological processes, eg "cell communication", "endocytosis". Comparative analysis between our dataset and publicly available datasets revealed EV-markers with potential discriminatory specificity for MM. Comparative analysis revealed 40 proteins differentially regulated between HD- and MM-EV (p <.05; log2 fold change ≥2). A specific protein signature was found in ≥30% of MM-EV vs ≤30% HD-EV. These proteins were not found in human whole plasma (Lehallier et al, Nat Med 2019) or solid tumors-EV (Hoshino et al, Cell 2020; Vinik et al, Science Advances 2020). 120 phosphosites were differentially expressed between HS5 pre-treated with MM-EV vs HD-EV (>1.5-fold change, p<.05). Among the differentially expressed proteins were kinases, phosphatases, translation and transcription regulators. 624 gene terms were differentially expressed between HS5 pre-treated

Infectious risks in newly diagnosed multiple myeloma (NDMM) patients receiving (or treated with) daratumumab based regimens: a multicentric Italian experience

Angela Rago[1], Francesca Fioritoni[2], Massimo Offidani[3], Ombretta Annibali[4], Roberta Poggiali[5], Tommaso Za[6], Luca Franceschini[7], Laura de Padua[8], Alfonso Piciocchi[9], Alessia Fiorini[10], Tommaso Caravita di Toritto[1]

[1]Asl Roma 1; [2]Asl Pescara; [3]Clinica di Ematologia, Azienda Ospedaliero-Universitaria delle Marche, Ancona, Italy; [4]Campus Biomedico; [5]Sapienza; [6]Gemelli; [7]Ptv, Roma; [8]Asl Frosinone; [9]Gimema; [10]Asl Viterbo

Introduction: Patients with multiple myeloma are at higher risk for infections due to disease pathogenesis and administered therapies. Infection is a significant cause of morbidity and the leading cause of death in patients (pts) with newly diagnosed multiple myeloma (NDMM). The risk of infection may be associated with neutropenia, hypogammaglobulinemia, and NK cell depletion. Daratumumab is approved for NDMM or relapsed/refractory multiple myeloma (RRMM). The use of daratumumab (dara) has improved patient outcomes but has changed the frequency and epidemiology of infections. The overall risk of infection with daratumumab treatment is around 38%, being upper respiratory tract infections the most common.The purpose of this study was to evaluate the number, the type and risk of infection events (IE) associated with the use of dara in patients with NDMM in the induction phase of transplant eligible and transplant ineligible NDMM patients. **Methods:** We retrospectively evaluated 308 pts with NDMM treatment in 8 Italian Hematology Centers who underwent induction therapy based on dara-bortezomib, thalidomide and dexamethasone (D-VTD), dara-lenalidomide and dexamethasone (D-Rd) and dara-bortezomib and dexamethasone (D-VMP) between 2020 and 2023.. **Results:** Overall, 105/308 (34%) developed an infection of any grade, 30/105 in D-VTD, 61/105in D-Rd and 14/105 in D-VMP arm. There was no difference on antiviral and antimicrobial prophylaxis in the 3 treatment groups. The median time to infection events was similar between the 3 groups D-VMP 161 days (104-243), D-Rd 156 days (97-370) and D-VTD 82 days (44-184) (p=0.064). Type of IE were upper respiratory tract infection in 81/105 pts (77%), SARS-COV2 infection 12/105 pts (11%), herpes simplex and varicella zoster virus (VZV) in 2/105 pts (1.9%), abdominal infection 3/105 pts (2.8%) and infection of urinary tract 2/105 pts (1.9%) of any grade. No differences were present in the grade and in the duration of IE. In all groups a statistically significant reduction was seen in the IgA level at the time of the IE (p=0.006), while no differences were present for IgG and IgM level in 3 treatment group. Moreover, a significant difference in neutropenia (p=0.002) and lymphocytophenia pre and post IE (p=0.006) resulted in all three groups. In our experience, no significant differences were found between the three treatment groups in terms of incidence, type and degree of infections, while significant differences were found between baseline IgA levels, neutropenia and lymphopenia at the time of the IE. **Conclusions:** A larger patient cohort and further studies are warranted to confirm these data and to identify patients at higher risk for infection, understanding the potential benefit of infectious prophylaxis in the clinical management in this setting of NDMM.

Novel pro-survival role for tryptophan 2,3 dioxygenase 2 in multiple myeloma

Julia Reinke[1], Kanita Chaudhry[2], Louise Carlson[1], Daniela Petrusca[1], Peng Peng[2], Kelvin Lee[3]

[1]Indiana University School of Medicine; [2]Roswell Park Comprehensive Cancer Center; [3]Melvin and Bren Simon Comprehensive Cancer Center, Division of Hematology and Oncology, School of Medicine, Indiana University

Introduction: Multiple Myeloma (MM) cells are critically dependent on the bone marrow microenvironment (BMME) for their survival. Our lab has previously shown that the CD28 receptor on MM cells interacting with its ligands CD80 and CD86 on dendritic cells (DC) in the BMME transduces an essential pro-MM survival/chemotherapy-resistance signal. "Backsignaling" through CD80/CD86 also leads to the upregulation/activation of Indoleamine 2,3-dioxygenase 1 (IDO1) in the DC. IDO1 catabolyzes tryptophan (TRP) to kynurenine (KYN) - leading to the depletion of TRP/accumulation of KYN in the BMME. TRP depletion suppressed T cell activation, and KYN activation of its receptor Aryl Hydrocarbon Receptor (AHR) transduces a significant pro-survival signal in vitro and in vivo to MM cells, in part by upregulating MM CD28 expression in a self-reinforcing feedback loop. MM cells express both CD28 and CD86; our lab has previously found that MM cells generate KYN in the absence of DC co-culture, indicating that MM cells are at least partially able to create this feedback loop on their own. This may assist MM in escaping its dependance on the BMME. Determining how MM cells independently facilitate the conversion of TRP>KYN could lead to greater understanding of survival pathways and new treatment targets. **Methods:** Patient RNA expression data was taken from the CoMMpass database. MM cell lines U266, 8226, MM1S and KMS11 were measured for expression of TRP>KYN metabolizing enzymes through western blot and qPCR. MM cell lines were treated with the tryptophan 2,3 dioxygenase 2 (TDO2) inhibitor or with TDO2 knockdown (KD) shRNA, and also with CD28 blocking peptides. Cell viability was measured by flow cytometry and KYN production by the Ehrlich KYN detection assay. **Results:** We found that MM cells don't express IDO1, but do express the TRP>KYN metabolizing enzyme TDO2. The biological role for TDO2 in MM is completely uncharacterized, but its significance is suggested by our finding that in patients, TDO2 expression increased with disease progression and that patients with the highest quartile of TDO2 expression have significantly shorter progression free and overall survival. Inhibition of TDO2 pharmacologically or by shRNA KD lead to significantly reduced cell viability. Treatment with CD28-blocking peptides lead to reduced production of KYN, indicating a previously unrecognized regulation of TDO2 by CD28. **Conclusions:** We have made the novel observations that MM cells express TDO2, which would allow them to generate TRP-depleted immunosuppression as well as pro-MM survival KYN-AhR signaling without an extrinsic BM ME partner. TDO2 expression correlates with disease progression and shorter PFS and OS in MM patients, and direct TDO2 inhibition in vitro kills MM cells. TDO2 expression in MM cells appears to be regulated at least in part by MM CD28, mirroring CD28's role in IDO1 induction in the BM ME. Altogether these findings suggest that TDO2 is a novel therapeutic target in MM.

Introduction: Subsets of patients with multiple myeloma (MM) and monoclonal gammopathies of undetermined significance (MGUS) present with a monoclonal immunoglobulin that specifically recognizes hepatitis C virus (HCV), which suggests that the plasmacytic clone may be HCV-driven in these patients. Supporting this hypothesis, antiviral treatment can lead to the disappearance of antigen stimulation and improved control of clonal plasma cells in HV-associated MGUS and MM patients. **Methods:** We investigated the role of hepatitis B virus (HBV) in the pathogenesis of MGUS and MM in 45 HBV-infected patients diagnosed with monoclonal gammopathy. Firstly, we analysed the specificity of recognition of the monoclonal immunoglobulin of these patients using the multiplex infectious antigen (MIAA) and dot blot assays. Secondly, we analysed the efficacy of antiviral treatment (AVT) in large cohorts of MM patients infected with HBV (n=1367) or HCV (n=1220) prior to the diagnosis of MM, in a federated database (Trinetx). **Results:** For 18/45 (40%) HBV-infected patients, the target of the monoclonal immunoglobulin was identified: the most frequent target was HBV (n=11), followed by other infectious pathogens (n=6) and a self-antigen, glucosylsphingosine (n=1). Two patients whose monoclonal immunoglobulin targeted HBV, implying that their gammopathy

with MM- vs HD-EV (GSEA, FDR < 0.05), including epidermal growth factor (EGF), tumor necrosis factor alpha (TNFA), epithelial to mesenchymal transition (EMT) signaling. **Conclusions:** In this first of its kind studies in MM we show that MM-EV may play a key role in disease progression by re-programming the TME. Ongoing studies will indicate: the value of MM-EV as biomarkers; whether targeting interactions between MM-EV and the (pre)metastatic niche could enforce current therapeutic strategies.

Introduction: Subsets of patients with multiple myeloma (MM) and monoclonal gammopathies of undetermined significance (MGUS) present with a monoclonal immunoglobulin that specifically recognizes hepatitis C virus (HCV), which suggests that the plasmacytic clone may be HCV-driven in these patients. Supporting this hypothesis, antiviral treatment can lead to the disappearance of antigen stimulation and improved control of clonal plasma cells in HV-associated MGUS and MM patients. **Methods:** We investigated the role of hepatitis B virus (HBV) in the pathogenesis of MGUS and MM in 45 HBV-infected patients diagnosed with monoclonal gammopathy. Firstly, we analysed the specificity of recognition of the monoclonal immunoglobulin of these patients using the multiplex infectious antigen (MIAA) and dot blot assays. Secondly, we analysed the efficacy of antiviral treatment (AVT) in large cohorts of MM patients infected with HBV (n=1367) or HCV (n=1220) prior to the diagnosis of MM, in a federated database (Trinetx). **Results:** For 18/45 (40%) HBV-infected patients, the target of the monoclonal immunoglobulin was identified: the most frequent target was HBV (n=11), followed by other infectious pathogens (n=6) and a self-antigen, glucosylsphingosine (n=1). Two patients whose monoclonal immunoglobulin targeted HBV, implying that their gammopathy

may be HBV-driven, received AVT and the gammopathy did not progress. AVT efficacy was then investigated in HBV-infected MM patients, who received anti-HBV treatments, or not, and compared to HCV-infected MM patients, who received anti-HBV treatments, or not. We show that AVT significantly improved patient probability of overall survival (p=0.016 for the HBV-positive cohort, p=0.005 for the HCV-positive cohort). **Conclusions:** MGUS and MM disease can be HBV- or HCV-driven in infected patients, and our study demonstrates the importance of antiviral treatments in such patients.

The effect of urolithin production by gut microbiota in multiple myeloma

Alba Rodríguez-García[1], Roberto García-Vicente[1], Raquel Ancos[1], Alejandra Ortiz-Ruiz[1], Andrés Arroyo[1], María Luz Morales[1], Miguel Ángel Navarro[1], Patricia Guevara-Ramírez[1], Pablo Justo[1], Victoria Selma[1], Francisco Tomás-Barberán[2], Rosa Ayala[1], Joaquín Martínez-López[3], María Linares[1]

[1]Department of Hematology, Hospital Universitario 12 de Octubre, Hematological Malignancies Clinical Research Unit H120-CNIO, Universidad Complutense de Madrid, Madrid, Spain; [2]Laboratory of Food & Health, Research Group on Quality, Safety, and Bioactivity of Plant Foods, CEBAS-CSIC; [3]Hematología Hospital 12 de Octubre, Madrid, Spain

Introduction: Recent studies have focused on understanding the role of the gut microbiota and its production of active metabolites in hematological malignancies, including multiple myeloma (MM). Urolithin A (UA) is a natural compound produced by gut microbiota from ellagic acid that has a positive influence on the regulation of biological functions and several physiological processes. Thus its effect has been reported as beneficial in numerous diseases, including cancer. In this work, we have characterized the human microbiota and its microbial metabolites, including UA, in different stages of MM from pre-malignant stages. We also have studied the possible therapeutic potential of this metabolite in MM. **Methods:** We collected 46 stool and serum samples from patients with monoclonal gammopathy of undetermined significance (n=11), smoldering myeloma (SMM) (n=9) and newly diagnosed multiple myeloma (NDMM) (n=9), at relapse/refractory (RRMM) and at complete remission (CRMM) (n=5). Furthermore, healthy patients (n=8) whose median age and gender ratio was similar to that of the patients, were included as controls. Taxonomic characterization in stool samples was performed by 16S rRNA using Illumina® MiSeq ™. LC-MS determined UA levels in serum samples. In vitro studies were performed on JJN3-GFP and U266-GFP MM cell lines as dose-response studies, western blot, immunohistochemistry, qPCR and flow cytometry. A MM xenograft model after 4 weeks of treatment with UA was used to validate the efficacy in mice. **Results:** We evaluated whether the levels of UA were changed by the monoclonal gammopathy progression and its response to treatment. When we classified patients according to whether or not they had detectable urolithins levels, we found that the majority group with undetectable levels was active MM (NDMM and RRMM) (56%), while only 15% of patients with urolithin detectable levels had active disease (p=0.043). When we analyzed the levels of the microbiota related to the production of urolithins, we found some microorganisms productors of UA we associated to achieving complete remission and a higher survival. The study of the treatment with UA showed an anti-proliferative effect in monotherapy and in combination with bortezomib in MM cell lines. UA treatment significantly improved survival in an in vivo model of MM, compared to the control group (p=0.0048). **Conclusions:** The presence of gut microbiota related to the production of UA and its levels were associated improving of response and survival in patients with MM. UA had an anti – tumor effect in an in vitro and in vivo a MM model. Our results suggests that this microbiota metabolite could have an anti-myeloma effect, although more studies are needed to validate its therapeutic potential.

Introduction: Trial in Progress. Menin, a protein involved in transcriptional regulation, cell cycle control, apoptosis, and DNA damage repair, plays a direct role in oncogenic signaling in multiple cancers. Inhibition of menin is therefore a novel approach to cancer treatment. Preclinical data of BMF-219, a highly selective, orally bioavailable, small-molecule covalent inhibitor of menin, show sustained potent abrogation of menin-dependent oncogenic

may be HBV-driven, received AVT and the gammopathy did not progress. AVT efficacy was then investigated in HBV-infected MM patients, who received anti-HBV treatments, or not, and compared to HCV-infected MM patients, who received anti-HBV treatments, or not. We show that AVT significantly improved patient probability of overall survival (p=0.016 for the HBV-positive cohort, p=0.005 for the HCV-positive cohort). **Conclusions:** MGUS and MM disease can be HBV- or HCV-driven in infected patients, and our study demonstrates the importance of antiviral treatments in such patients.

Introduction: Recent studies have focused on understanding the role of the gut microbiota and its production of active metabolites in hematological malignancies, including multiple myeloma (MM). Urolithin A (UA) is a natural compound produced by gut microbiota from ellagic acid that has a positive influence on the regulation of biological functions and several physiological processes. Thus its effect has been reported as beneficial in numerous diseases, including cancer. In this work, we have characterized the human microbiota and its microbial metabolites, including UA, in different stages of MM from pre-malignant stages. We also have studied the possible therapeutic potential of this metabolite in MM. **Methods:** We collected 46 stool and serum samples from patients with monoclonal gammopathy of undetermined significance (n=11), smoldering myeloma (SMM) (n=9) and newly diagnosed multiple myeloma (NDMM) (n=9), at relapse/refractory (RRMM) and at complete remission (CRMM) (n=5). Furthermore, healthy patients (n=8) whose median age and gender ratio was similar to that of the patients, were included as controls. Taxonomic characterization in stool samples was performed by 16S rRNA using Illumina® MiSeq ™. LC-MS determined UA levels in serum samples. In vitro studies were performed on JJN3-GFP and U266-GFP MM cell lines as dose-response studies, western blot, immunohistochemistry, qPCR and flow cytometry. A MM xenograft model after 4 weeks of treatment with UA was used to validate the efficacy in mice. **Results:** We evaluated whether the levels of UA were changed by the monoclonal gammopathy progression and its response to treatment. When we classified patients according to whether or not they had detectable urolithins levels, we found that the majority group with undetectable levels was active MM (NDMM and RRMM) (56%), while only 15% of patients with urolithin detectable levels had active disease (p=0.043). When we analyzed the levels of the microbiota related to the production of urolithins, we found some microorganisms productors of UA we associated to achieving complete remission and a higher survival. The study of the treatment with UA showed an anti-proliferative effect in monotherapy and in combination with bortezomib in MM cell lines. UA treatment significantly improved survival in an in vivo model of MM, compared to the control group (p=0.0048). **Conclusions:** The presence of gut microbiota related to the production of UA and its levels were associated improving of response and survival in patients with MM. UA had an anti – tumor effect in an in vitro and in vivo a MM model. Our results suggests that this microbiota metabolite could have an anti-myeloma effect, although more studies are needed to validate its therapeutic potential.

Introduction: Trial in Progress. Menin, a protein involved in transcriptional regulation, cell cycle control, apoptosis, and DNA damage repair, plays a direct role in oncogenic signaling in multiple cancers. Inhibition of menin is therefore a novel approach to cancer treatment. Preclinical data of BMF-219, a highly selective, orally bioavailable, small-molecule covalent inhibitor of menin, show sustained potent abrogation of menin-dependent oncogenic

signaling in vitro and in vivo. BMF-219 exhibited a strong anti-proliferative effect on various menin-dependent cell lines including acute myeloid leukemia (AML), diffuse large B-cell lymphoma (DLBCL) representing Double/Triple Hit Lymphoma (DHL/THL) & Double Expressor Lymphoma (DEL), multiple myeloma (MM) with diverse mutational backgrounds. BMF-219 also exhibits high potency ex vivo in patient samples from MLL-rearranged and NPM1-mutant AML, THL and MYC-amplified DLBCL, bone marrow mononuclear cells from treatment-naive and R/R MM, and CLL patient specimens with various cytogenetic backgrounds. **Methods:** COVALENT-101 is a prospective, open-label, multi-cohort, non-randomized, Phase I study evaluating the safety, tolerability, and clinical activity of escalating doses of BMF-219 in patients with relapsed or refractory (R/R) acute leukemia (AL), DLBCL, MM and CLL who have received standard therapy. The primary objective of the study is to determine independently for each cohort, the optimal biological dose/recommended Phase 2 dose of BMF-219 monotherapy. Key secondary objectives include further evaluation of safety and tolerability, characterization of the pharmacodynamics and pharmacokinetics of BMF-219, and assessment of antitumor activity based on best overall response rate, duration of response, progression-free survival, and time to progression. Food-effect studies will be performed at certain dose levels. Utilizing an accelerated titration design, doses of BMF-219 will be escalated in single-subject cohorts independently for each indication until 1 subject experiences either a ≥ Grade 2 related adverse event or dose limiting toxicity. At that point, the cohort will switch to a classical "3 + 3" design. Treatment continues in 28-day cycles until progression or intolerability. Expansion cohorts for each indication will be enrolled to obtain further safety and efficacy data. Patients with R/R AL, DLBCL who received at least 2 prior therapies, MM who received at least 3 prior therapies, CLL who received at least 2 prior therapies and have either failed or are ineligible for any standard therapies are eligible. Patients must have ECOG PS ≤ 2, and adequate organ function. Key exclusion criteria include known CNS disease involvement and clinically significant cardiovascular disease. **Results:** As of May 2023 the study is enrolling at 16 sites in the United States, Spain and the Netherlands. Other European sites in Greece, Italy and France are in startup. **Conclusions:** Enrollment commenced in January 2022 in the United States and in May 2023 in Europe.

A phase 2 trial of leflunomide, pomalidomide, and dexamethasone for relapsed/refractory multiple myeloma

Michael Rosenzweig[1], James Sanchez[1], Arnab Chowdhury[1], Nitya Nathwani[1], Murali Janakiram[1], Myo Htut[1], Firoozeh Sahebi[1], Tricia Walker[1], Flavia Pichiorri[1], Joycelynne Palmer[1], Amrita Krishnan[1], Jonathan Keats[1,2], Steven Rosen[1]

[1]City of Hope National Comprehensive Cancer Center; [2]Translational Genomics Research Institute

Introduction: Patients with relapsed/refractory multiple myeloma (RRMM) are in need of new and effective therapies. Many treatments today pose a high burden in terms of cost, toxicity, and route of administration. Leflunomide is an inexpensive, commercially available, oral immunosuppressive approved for treating rheumatoid arthritis. Our published preclinical data (Buettner et al., Blood Adv vol. 3, pp. 1027-1032) suggested a a therapeutic benefit of using leflunomide for MM as well as synergy with immunomodulatory drugs. We then assessed the clinical translation of these findings by opening a phase 2 trial of leflunomide in combination with pomalidomide and dexamethasone for the treatment of RRMM. **Methods:** Primary Objective: To estimate the overall response rate (ORR) of the three-drug combination in patients (pts) with RRMM. Secondary objectives: 1) to characterize and evaluate toxicities; 2) to obtain estimated duration of response (DoR) and time to progression, clinical benefit, and survival (overall [OS] and progression-free [PFS]). Leflunomide is administered orally with a loading dose of 100 mg daily for the first 3 days followed by 20 mg daily thereafter. Cycles are 28 days. Pomalidomide is administered at a starting dose of 4 mg PO on days 1-21, and dexamethasone is given at a dose of 40 mg PO (20 mg for participants over 75) on days 1, 8, 15, and 22. Pts are followed monthly for toxicity and response and continue treatment until disease progression or failure to tolerate the regimen. **Results:** A total of 11 pts have been enrolled to date, with 9 pts evaluable for response. The median age of the cohort is 53; 6 pts are male and 3 are female. The median number of prior lines of therapy is 2 (range 1-4). Of the evaluable pts, 4 had clasic high-risk cytogentics, and a total of 5 pts had gain of 1q by FISH. Three pts were refractory to lenalidomide, 3 to bortezomib and 1 to anti-CD38 monoclonal antibody. All 9 evaluable pts were pomalidomide naïve. The ORR was 44% with a median DoR of 7.5 months. The median time to progression has not been reached. At 1 year, 51% of patients have not progressed. The most common adverse events (AEs) were hematologic. One pt had grade 4 thrombocytopenia, which was a dose limiting toxicity. Grade 3 AEs included lymphopenia (1 pt) and neutropenia (3 pts). One additonal pt had grade 2 neutropenia. Grade 3 non-hematologic AEs included hypophosphatemia (1 pt) and diarrhea (1 pt). Grade 2 non-hematologic AEs included peripheral neuropathy (1 pt), squamous cell carcinoma (1 pt), and fever (1 pt). **Conclusions:** Leflunomide, pomalidomide, and dexamethasone represent an all-oral treatment that appears safe and well tolerated in all 9 patients we treated thus far. Early ORR and DoR data are encouraging and compare favorably to an earlier phase 3b study of pomalidomide and dexamethasone, which demonstrated an ORR of 32.6%, median DoR of 7.4 months, and median PFS of 4.6 months. Our study has now met criteria to proceed to the second stage, and enrollment will continue.

We then assessed the clinical translation of these findings by opening a phase 2 trial of leflunomide in combination with pomalidomide and dexamethasone for the treatment of RRMM. **Methods:** Primary Objective: To estimate the overall response rate (ORR) of the three-drug combination in patients (pts) with RRMM. Secondary objectives: 1) to characterize and evaluate toxicities; 2) to obtain estimated duration of response (DoR) and time to progression, clinical benefit, and survival (overall [OS] and progression-free [PFS]). Leflunomide is administered orally with a loading dose of 100 mg daily for the first 3 days followed by 20 mg daily thereafter. Cycles are 28 days. Pomalidomide is administered at a starting dose of 4 mg PO on days 1-21, and dexamethasone is given at a dose of 40 mg PO (20 mg for participants over 75) on days 1, 8, 15, and 22. Pts are followed monthly for toxicity and response and continue treatment until disease progression or failure to tolerate the regimen. **Results:** A total of 11 pts have been enrolled to date, with 9 pts evaluable for response. The median age of the cohort is 53; 6 pts are male and 3 are female. The median number of prior lines of therapy is 2 (range 1-4). Of the evaluable pts, 4 had clasic high-risk cytogentics, and a total of 5 pts had gain of 1q by FISH. Three pts were refractory to lenalidomide, 3 to bortezomib and 1 to anti-CD38 monoclonal antibody. All 9 evaluable pts were pomalidomide naïve. The ORR was 44% with a median DoR of 7.5 months. The median time to progression has not been reached. At 1 year, 51% of patients have not progressed. The most common adverse events (AEs) were hematologic. One pt had grade 4 thrombocytopenia, which was a dose limiting toxicity. Grade 3 AEs included lymphopenia (1 pt) and neutropenia (3 pts). One additonal pt had grade 2 neutropenia. Grade 3 non-hematologic AEs included hypophosphatemia (1 pt) and diarrhea (1 pt). Grade 2 non-hematologic AEs included peripheral neuropathy (1 pt), squamous cell carcinoma (1 pt), and fever (1 pt). **Conclusions:** Leflunomide, pomalidomide, and dexamethasone represent an all-oral treatment that appears safe and well tolerated in all 9 patients we treated thus far. Early ORR and DoR data are encouraging and compare favorably to an earlier phase 3b study of pomalidomide and dexamethasone, which demonstrated an ORR of 32.6%, median DoR of 7.4 months, and median PFS of 4.6 months. Our study has now met criteria to proceed to the second stage, and enrollment will continue.

Introduction: Multiple myeloma (MM) is associated with significant DNA damage and genomic instability, enabling them to acquire new characteristics for growth and disease progression. We previously identified apurinic/apyrimidinic nuclease 1 (APEX1) as part of a gene signature that correlated with genomic instability in MM cells. APEX1 is best known for its critical role in the base-excision repair pathway. However, APEX1 is also known to participate in transcriptional regulation. In multiple myeloma cells, APEX1 binds to P73 at the RAD51 promotor to regulate the expression of RAD51, a key factor in homologous DNA repair (HR). **Methods:** To find APEX1-interaction sites throughout the myeloma genome, we did Chromatin Immuno-precipitation (IP) with APEX1 antibody followed by sequencing (ChIP-seq). To find APEX1 and RAD51 proteomes in myeloma cells, we performed IP using APEX1, RAD51 or IgG followed by mass spectrometry. **Results:** Using ChIP-seq, we found that ~60% of the APEX1 interaction sites are in the expressed regions of the genome i.e., in promoters, exons, introns or UTRs. APEX1 was predominantly bound to genes involved in immune function, growth, and cancer-related pathways. Interestingly, treatment with camptothecin (CPT), a chemical that induces double-strand DNA breaks, redirected APEX1 to genes involved in the cell cycle, DNA repair, mTOR signaling and cancer-related pathways. Some of the genes where APEX1 peaks appeared were TP53 (involved in DNA repair and apoptosis), GADD 45B (involved in DNA repair, cell cycle and the ability of the cell to cope with genotoxic stress), LMNA (involved in the maintenance of chromatin structure, telomeres, DNA repair and gene expression), IKBKB (involved in immune response, growth control) and MAP2K1 (involved in growth, adhesion, survival and differentiation). Since coordination among cell cycle, DNA repair and apoptosis pathways is required for regulating growth and genome stability, our data suggest a possible role of APEX1 in the coordination of these vital processes. We previously demonstrated that elevated APEX1 impacts genome stability through dysregulation of base excision repair as well as HR. To further study the mechanisms and protein networks involved in APEX-related dysregulation of HR and genomic instability, we investigated proteins interacting with APEX1 and RAD51. Thirteen proteins were common in APEX1 and RAD51 proteomes. For example, PARP1, which contributes to both single and double stranded DNA break repair (through recruitment of BRCA1), is part of both APEX1 and RAD51 proteomes. This further confirms the functional link between APEX1 (base excision repair) and RAD51 (HR) related pathways. **Conclusions:** Our data suggest that APEX1, in addition to its canonical DNA repair function, is also involved in the regulation of the cell cycle, apoptosis and multiple DNA repair pathways and may assist in coordination of these vital processes. Thus, inhibitors of APEX1 have the potential to target genomic instability and growth of MM cells.

The PBK-FOXM1 axis disrupts the DREAM transcriptional repressor complex, contributing to the growth and genomic instability of myeloma

Lai Shi[1], Srikanth Talluri[1], Subodh Kumar[1], Jiangning Zhao[1], Laksmi Potluri[2], Chengcheng Liao[1], Leutz Buon[1], Chandraditya Chakraborty[1], Masood Shammas[1], Nikhil Munshi[3]

Introduction: The dysregulation of cell cycle checkpoints and DNA repair pathways is a common feature of cancer cells and contributes to their continued growth and genomic evolution. Previously, we identified a six-gene kinase signature that correlated with genomic instability in nine human cancers including multiple myeloma (MM). PBK, a top kinase in the signature, was investigated further. The DREAM complex represses cell cycle genes during quiescence through scaffolding MuvB proteins with E2F4-p130. Upon cell cycle entry, MuvB dissociates from E2F4 and recruits FOXM1 for up-regulating mitotic gene expression. **Methods:** RNA sequencing was done following PBK inhibition to investigate the genes/pathways regulated by PBK. Co-immunoprecipitation followed by western blotting and/or mass-spectrometry was done to find interacting partners of PBK, LIN54 and FOXM1. To investigate FOXM1 regulated genes following PBK inhibition, we performed Chromatin Immunoprecipitation (ChIP), followed by qPCR. Subcutaneous xenograft study using MM cells was done to evaluate the in vivo efficacy of the PBK inhibitor. **Results:** RNA seq. analysis showed that E2F and FOXM1 were among the top six pathways down-regulated by the PBK inhibitor and that there was a notable overlap between the affected genes and target genes of the DREAM complex. Using Co-IP and ChIP experiments, we found that PBK interacts with and phosphorylates FOXM1, thus upregulating FOXM1 target genes such as RAD51, EXO1 and CDC25a. To get further insight into PBK-mediated regulation of the DREAM complex, we immunoprecipitated LIN54 (a major component of MuvB) in PBK-overexpression and PBK-knockdown MM cells. We found that PBK-overexpression increases the phosphorylated FOXM1-LIN54 interaction and disrupts the repressive DREAM complex, as evident from reduced LIN54-E2F4 interaction. On the contrary, PBK-knockdown or PBK inhibitor promoted the DREAM repressive complex (LIN54-E2F4 interaction) and reduced the phosphorylated FOXM1-LIN54 interaction. These data demonstrate that elevated PBK disrupts the repressive DREAM complex by dissociating MUVB from E2F4 and recruiting it to FOXM1, thus promoting mitosis and contributing to genomic instability. Consistently, the comparative gene expression profiling of paired myeloma cell samples collected at diagnosis and again after chemotherapy (melphalan) relapse (GSE19554), showed significant upregulation of PBK at relapse. In MM cells, treatment with PBK inhibitor inhibited spontaneous and chemotherapy-induced genomic instability ($P < 0.05$), as assessed by micronucleus assay. Moreover, in a subcutaneous mouse model of MM, treatment with PBK inhibitor also impaired tumor growth and significantly

ULK3-mediated autophagy is a tractable therapeutic target for the treatment of multiple myeloma

Marilena Tauro[1], Tao Li[1], Mark Meads[1], Praneeth Sudalagunta[1], Raghunandan Alugubelli[1], Nicholas Lawrence[1], Ernst Schinbrunn[1], Ryan Bishop[1], Harshani Lawrence[1], Ken Shain[1], Conor Lynch[1]

[1]H Lee Moffitt Cancer Center

Introduction: Multiple myeloma (MM) remains incurable despite advances in therapy. Our group is the first to demonstrate that ULK3-mediated autophagy in MM is a key program that sustains cell survival upon treatment. MM is characterized by high basal levels of autophagy and, currently, specific ULK3 inhibitors are lacking. Here we have generated novel multiple kinase inhibitors that can block ULK3 activity and demonstrate their efficacy in vitro, in vivo and in ex vivo human specimens. **Methods:** We performed RNASeq analysis of CD138+ MM patient cells collected at the Moffitt Cancer Center (n=815) and demonstrated ULK3 is highly expressed across the disease spectrum. We also show it is crucial for MM progression using CRISPR and in vivo preclinical models (5TGM1Luc, U266Luc). We characterized novel small molecule inhibitors SG3014/MA9060 that target multiple kinases including ULK3 with nanomolar potency and demonstrate their impact on MM cell viability. We also use a novel ex vivo platform developed at Moffitt to demonstrate the efficacy of these reagents and their effect on ULK3 mediated autophagy. **Results:** ULK3 protein levels correlate with MM patients' progression stages. In fact, refractory patients have increased autophagy activity and significantly higher expression of ULK3. Genetic ablation of ULK3 by CRISPR guides in U266/ 8226/ MM1.S cell lines results in rapid cessation of the downstream autophagy mediators (ULK1, ATG13, pATG13). Importantly, using a vesicle labelling tool (CytoID), we demonstrated shutdown of autophagy in ULK3 knockout cells. We also show that MA9060/SG3014 decrease ULK3 levels and autophagy as measured by immunoblot and CytoID. Using an in vivo model of MM progression in the skeleton (U266) we observed that MA9060 reduced tumor burden, protected against myeloma induced bone disease and significantly extended overall survival (CTRL untreated n=65 days vs MA9060 n=110 days). Importantly, we noted no overt toxicity and protected effect against myeloma-induced bone disease. Ex vivo, we demonstrated the efficacy of MA9060 for the treatment of CD138+ MM derived from newly diagnosed and refractory patients both as a single agent and in combination with standard of care therapies such as the proteasome inhibitor, carfilzomib. **Conclusions:** ULK3 is a key regulator of autophagy in multiple myeloma and its genetic or pharmacological inhibition significantly limits MM viability making it an attractive therapeutic target for the treatment of the disease.

TLR-activation may promote drug resistance and disease progression in multiple myeloma

Synne Stokke Tryggestad[1], Kristin Roseth Aass[1], Ingrid Aass Roseth[1], Therese Standal[1]

[1]Norwegian University of Science and Technology

Introduction: Myeloma patients suffer from recurrent and chronic infections due to immune suppression and anti-myeloma treatment. Infections may be life threatening and is a major cause of death for the patients. Whether infectious agents can contribute to disease progression by directly affecting myeloma cell aggressiveness and drug resistance is, however, less explored. Toll-like receptors (TLRs) are a group of pattern recognition receptors recognizing conserved microbial structures, and TLRs may be expressed by myeloma cells. **Methods:** We analyzed TLR gene expression in samples from 772 myeloma patients (CoMMpass IA14). In vitro, we challenged the myeloma cell line RPMI-8226 with TLR4 agonist LPS and TLR9 agonist CpG, and assessed the effect on cell viability and proliferation, as well as expression of a range of pro-survival and anti-apoptotic factors. Lastly, we assessed the effect of TLR-activation on MM cell drug sensitivity towards proteasome inhibitors bortezomib and carfilzomib. **Results:** We show that primary myeloma cells expressed a broad range of TLRs, and TLR4 and TLR9 were among the most highly expressed receptors. When we challenged the myeloma cell line RPMI-8226 with TLR4 agonist LPS and TLR9 agonist CpG, both cell viability and proliferation was increased. TLR-stimulation did also upregulate protein expression of a range of well-known pro-survival and anti-apoptotic factors in myeloma, including c-Myc, IRF4, Mcl-1 and Bcl-2. Further, when we treated RPMI-8226 cells with a combination of TLR agonists and proteasome inhibitors bortezomib and carfilzomib, the cells' drug sensitivity was reduced. The reduction in drug sensitivity is mediated by TLR-signaling, since the protective effect of TLR-stimulation was lost in cells depleted for TLR4 and TLR9. **Conclusions:** We show that stimulation with TLR agonists LPS and CpG promotes myeloma cell aggressiveness and drug resistance. Our data suggest that infections may give the cancer cells a survival benefit through upregulation of pro-survival and anti-apoptotic factors, and that myeloma patients may benefit from combinations of anti-tumor and anti-infection/TLR-inhibitor treatment.

MM is characterized by high basal levels of autophagy and, currently, specific ULK3 inhibitors are lacking. Here we have generated novel multiple kinase inhibitors that can block ULK3 activity and demonstrate their efficacy in vitro, in vivo and in ex vivo human specimens. **Methods:** We performed RNASeq analysis of CD138+ MM patient cells collected at the Moffitt Cancer Center (n=815) and demonstrated ULK3 is highly expressed across the disease spectrum. We also show it is crucial for MM progression using CRISPR and in vivo preclinical models (5TGM1Luc, U266Luc). We characterized novel small molecule inhibitors SG3014/MA9060 that target multiple kinases including ULK3 with nanomolar potency and demonstrate their impact on MM cell viability. We also use a novel ex vivo platform developed at Moffitt to demonstrate the efficacy of these reagents and their effect on ULK3 mediated autophagy. **Results:** ULK3 protein levels correlate with MM patients' progression stages. In fact, refractory patients have increased autophagy activity and significantly higher expression of ULK3. Genetic ablation of ULK3 by CRISPR guides in U266/ 8226/ MM1.S cell lines results in rapid cessation of the downstream autophagy mediators (ULK1, ATG13, pATG13). Importantly, using a vesicle labelling tool (CytoID), we demonstrated shutdown of autophagy in ULK3 knockout cells. We also show that MA9060/SG3014 decrease ULK3 levels and autophagy as measured by immunoblot and CytoID. Using an in vivo model of MM progression in the skeleton (U266) we observed that MA9060 reduced tumor burden, protected against myeloma induced bone disease and significantly extended overall survival (CTRL untreated n=65 days vs MA9060 n=110 days). Importantly, we noted no overt toxicity and protected effect against myeloma-induced bone disease. Ex vivo, we demonstrated the efficacy of MA9060 for the treatment of CD138+ MM derived from newly diagnosed and refractory patients both as a single agent and in combination with standard of care therapies such as the proteasome inhibitor, carfilzomib. **Conclusions:** ULK3 is a key regulator of autophagy in multiple myeloma and its genetic or pharmacological inhibition significantly limits MM viability making it an attractive therapeutic target for the treatment of the disease.

TLR-activation may promote drug resistance and disease progression in multiple myeloma

Synne Stokke Tryggestad[1], Kristin Roseth Aass[1], Ingrid Aass Roseth[1], Therese Standal[1]

[1]Norwegian University of Science and Technology

Introduction: Myeloma patients suffer from recurrent and chronic infections due to immune suppression and anti-myeloma treatment. Infections may be life threatening and is a major cause of death for the patients. Whether infectious agents can contribute to disease progression by directly affecting myeloma cell aggressiveness and drug resistance is, however, less explored. Toll-like receptors (TLRs) are a group of pattern recognition receptors recognizing conserved microbial structures, and TLRs may be expressed by myeloma cells. **Methods:** We analyzed TLR gene expression in samples from 772 myeloma patients (CoMMpass IA14). In vitro, we challenged the myeloma cell line RPMI-8226 with TLR4 agonist LPS and TLR9 agonist CpG, and assessed the effect on cell viability and proliferation, as well as expression of a range of pro-survival and anti-apoptotic factors. Lastly, we assessed the effect of TLR-activation on MM cell drug sensitivity towards proteasome inhibitors bortezomib and carfilzomib. **Results:** We show that primary myeloma cells expressed a broad range of TLRs, and TLR4 and TLR9 were among the most highly expressed receptors. When we challenged the myeloma cell line RPMI-8226 with TLR4 agonist LPS and TLR9 agonist CpG, both cell viability and proliferation was increased. TLR-stimulation did also upregulate protein expression of a range of well-known pro-survival and anti-apoptotic factors in myeloma, including c-Myc, IRF4, Mcl-1 and Bcl-2. Further, when we treated RPMI-8226 cells with a combination of TLR agonists and proteasome inhibitors bortezomib and carfilzomib, the cells' drug sensitivity was reduced. The reduction in drug sensitivity is mediated by TLR-signaling, since the protective effect of TLR-stimulation was lost in cells depleted for TLR4 and TLR9. **Conclusions:** We show that stimulation with TLR agonists LPS and CpG promotes myeloma cell aggressiveness and drug resistance. Our data suggest that infections may give the cancer cells a survival benefit through upregulation of pro-survival and anti-apoptotic factors, and that myeloma patients may benefit from combinations of anti-tumor and anti-infection/TLR-inhibitor treatment.

Investigating the proteasome stress response as a potential therapeutic target in multiple myeloma

Cameron Van Cleave[1], Tianzeng Chen[1], Matthew Ho[2], Maria Moscvin[1], Peter Czarnecki[3], Giada Bianchi[1]

[1]Brigham and Women's Hospital/Harvard Medical School; [2]Mayo Clinic; [3]Beth Israel Deaconess Medical Center/Harvard Medical School

Introduction: Multiple myeloma (MM) is the second most common hematological malignancy in the world and remains largely incurable. We previously demonstrated that MM cells are dependent on intact proteostasis mechanisms and are specifically sensitive to perturbations of this balance. For instance, proteasome inhibitors (PI) such as bortezomib, carfilzomib and ixazomib are part of the treatment of MM across all stages of disease. However, acquired resistance is inevitable for most patients, leading to shorter remissions and eventual patient demise. New therapeutic strategies to overcome resistance are therefore urgently needed. We recently showed that the aspartic protease DDI2 is necessary for MM cell survival due to its critical role in activating the proteasome stress response (PSR) master-regulator NRF1, leading to de novo proteasome subunit transcription. We hypothesized that targeting DDI2 is a novel therapeutic strategy in MM. Specific DDI2 inhibitors are not available and mammalian reporter cell lines of PSR activation do not exist, limiting our capabilities to successfully screen for new compounds. We herein set out to develop MM reporter cell lines to conduct high-throughput repurposing screening of FDA-approved small molecules. **Methods:** We generated a reporter construct comprising 8 repeats of antioxidant response elements (ARE) upstream of a minimal promoter followed by destabilized GFP. To monitor for successful transfection, copy number integration and global changes in transcription, the same construct will lead to expression of mCherry under an EF1α promotor. We transduced MM cell lines with varying baseline sensitivities to PI with this construct. We also used AMO1-VR, but DDI2 WT and DDI2 KO, as a model of acquired bortezomib resistance with intact or impaired PSR. To induce PSR, we pulse treated cells with a sublethal dose of carfilzomib as previously described (Chen et al, Blood Adv 2022) and monitored changes in the ratio of GFP/mCherry intensity over time via flow cytometry and immunofluorescence. **Results:** We found that the reporter cell lines showed a peak of GFP/mCherry intensity 8-12 hours after pulse treatment with carfilzomib, consistent with our prior data showing peak of proteasome subunit transcription after PI treatment around 10 hours. Importantly, the GFP/mCherry ratio returned to baseline after approximately 24 hours from treatment, in the absence of significant cell apoptosis. DDI2 KO AMO1-VR showed significantly blunted peak of GFP/mCherry intensity, consistent with reduced capability of de novo proteasome subunit transcription. **Conclusions:** Our data showed that we have successfully developed the first mammalian reporter cell line of PSR with preliminary data showing adequate delta and kinetics to assist in pharmacological screening of molecules blocking the PSR and inducing apoptosis in MM. This powerful tool will inform screening and subsequent validation of newly found/synthesized DDI2 inhibitors, currently under development.

Introduction: Innovative immunotherapy approaches such as adoptive transfer of chimeric antigen receptor (CAR) T cells or tumor infiltrating lymphocytes (TILs) have shown great success in the treatment of solid tumors and hematological malignancies. Although treatment of multiple myeloma with CAR T cells can induce deep responses, relapses frequently occur due to antigen escape and limited CAR T cell persistence. TCR-engineered T cells may show prolonged persistence in vivo and could mediate sustained antitumor effects. A further benefit of TCR transgenic T cells is the ability to target intracellular antigens that are inaccessible to CAR T cells, expanding the range of potential targets for immunotherapy. **Methods:** In our project, we propose to identify T cell receptors (TCRs) specifically targeting autologous myeloma cells. Tumor-reactive T cells were identified using the Berkeley Lights Lightning platform, allowing simultaneous functional analysis of up to 1500 individual T cell/target cell interactions on a chip. Reactive T cells were identified upon detection of secreted cytokines (IFNγ, TNFα, IL¬ 2) and measurement of 4-1BB (CD137) surface expression. **Results:** Tumor-reactive T cells showing various cytokine secretion patterns and 4-1BB expression profiles were detected in each myeloma patient (7 to 26 cells of approx. 1500 cells tested per patient). Individual tumor-reactive T cells have been isolated and their TCRs were sequenced. TCR sequences of tumor-reactive T cells were mapped to single-cell RNA sequencing data of individual multiple myeloma patients to reveal gene expression signatures of myeloma-reactive T cells. TCR genes of reactive T cells were cloned and overexpressed in autologous T cells for functional validation and analysis of tumor derived neoepitope specificity. **Conclusions:** In summary, we present a pipeline allowing identification of myeloma-recognizing T cells and recovery of bona fide tumor-reactive TCRs eligible for patient-individualized T cell therapy.

PIM2 kinase regulates TIGIT expression and energy metabolism in NK cells from multiple myeloma patients

Hao Wang[1], Zhaoyun Liu[1], Rong Fu[1]
[1]Tianjin Medical University General Hospital

Introduction: PIM2 kinase is highly expressed in myeloma cells and reportedly inhibits their apoptosis,participates in the pathogenesis of myeloma bone disease, negatively regulates T cell-mediated immune response, and maintains B cell proliferation before survival restriction. However, only a few studies have examined the effects of PIM2 kinase on NK cell function in patients with multiple myeloma (MM).The functional suppression of NK cells through surface immune checkpoints is a key mechanism of immune escape in MM. One of the immune checkpoints, TIGIT, is highly expressed on NK cells in patients with MM and binds to PVR/CD155 to inhibit NK cell function. Previous studies have shown that of the presence of NK cells and the expression of IFN-γ, CD107a, TNF, and other molecules are reduced in the tumor microenvironment. Therefore, immunotherapy targeting NK cells has become a new idea of tumor immunotherapy.Although PIM2 kinase is known to regulate T and B cells, its role in natural killer (NK) cells remains unclear.To investigate the effect and mechanism of Pim-2 kinase inhibitor on NK cell therapy. **Methods:** PIM2 kinase expression was analyzed in NK cells from MM patients and healthy donors using single-cell RNA sequencing (RNA-seq). Immune checkpoint expression, cell apoptosis, and NK cell function were evaluated using flow cytometry. The TIGIT promoter was predicted using NCBI, UCSC, JASPAR, and GEPIA databases. NK-92 cells with ETS-1 knockdown were established using shRNA. PIM2 kinase inhibition by 160 natural flavonoids was analyzed using kinase functional assays (ADP-Glo), mass spectrometry, and RNA-seq. The oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) were measured using assay kits. the expression of TIGIT on NK cells, cell apoptosis, and NK cell function were detected using flow cytometry in U266 cells and NK-cells co-culture system or U266 cells, bone marrow mesenchymal stem cell (BMSC) and NK-cells co-culture. **Results:** PIM2 kinase was highly expressed in NK cells from patients with MM and PIM2 kinase inhibition increased NK cell function and downregulated TIGIT expression. ETS-1, which binds directly to the TIGIT promoter, was upregulated by PIM2 kinase, thereby increasing TIGIT transcription in NK cells. The natural flavonoids kaempferol and quercetin dihydrate inhibited PIM2 kinase with higher efficiency, at low doses in MM cells and altered TIGIT expression and energy metabolism in NK-92 cells. PIM2 kinase inhibitors activated NK cell killing and decreased TIGIT expression in vitro, while promoting MM cell apoptosis. **Conclusions:** PIM2 kinase regulates NK cell anti-myeloma activity by modulating TIGIT expression and energy metabolism.

[1]Cleveland Clinic Lerner Research Institute; [2]Cleveland Clinic Taussig Cancer Institute; [3]Cleveland Clinic Lerner College of Medicine

Introduction: Monoclonal antibody (mAb) drugs are already in clinical use to treat multiple myeloma (MM) but all MM patients eventually develop drug resistance. Therefore, novel targeted therapy is urgently needed to overcome the drug resistance. The plasma cell-induced ER resident protein 1 (pERP1) is one of the co-chaperone proteins specifically required for the differentiation and function of antibody-secreting cells in a T cell independent immune response. High pERP1 expression has been specifically linked to B cell malignancy such as chronic lymphocytic leukemia, follicular lymphoma, and diffuse large B-cell lymphoma correlates with poorer prognosis and shorter survival times in patients. The expression pattern of pERP1 in MM patients is unclear. **Methods:** We performed 10X scRNA seq analysis to simultaneously identify distinct immune cell populations and MM cells using bone marrow samples from patients. Through scRNA seq analysis, we identified the most highly upregulated and downregulated genes in each immune cell cluster. To test whether pERP1 might be a novel immunotarget for MM treatment, we have developed an pERP1 antibody drug conjugate (ADC). We further tested pERP1 ADC in our newly developed preclinical third generation AIDCreERT2+/-, EYFP LSL/-, P53L/L, BrafV600ELSL/-, cMYCLSL/- (AEY-PVM) MM mouse model. **Results:** By means of single cell RNA seq analysis, we identified the most upregulated gene signatures in patients to include those of CD138, CD38, BCMA, and pERP1. When we look for other chaperone proteins including GRP78 and GRP94, we found them to be broadly expressed in bone marrow cells while not finding specific expression in the MM cell population, which underscoring the importance of pERP1 in the development of MM and its potential as a therapeutic target. Our studies further demonstrate high expression of pERP1 on the surface of MM cell lines and on CD138+ plasma cells in MM patients as compared with those from healthy donors. Then, we developed a pERP1 ADC against human pERP1 antigen, verified by using Biacore S200 Surface Plasmon Resonance (SPR) assay. We determined the IC50 of the pERP1 ADC drug against the human cell line RPM18226 to be 1.034 nM. We then tested the pERP1ADC drug in our third generation AEY-PVM mice after they developed MM disease as determined by M spike detection on an SPE gel. We used only 1.25mg/kg of the pERP1 ADC drug, which is lower than the dose of the currently clinically used ADC drugs belantamab mafodotin (2.5-3.4 mg/kg), to treat the AEY-PVM MM mice. Furthermore the survival data from 5 MZB1-ADC treated AEY-PMV mice and 5 control mice confirmed that pERP1 mAb can significantly prolong the survival of AEY-PMV MM mice. **Conclusions:** In conclusion,

Introduction: Treatment options in patients with RRMM refractory to bortezomib (V) and lenalidomide (R) are limited. Potential approved treatment options include pomalidomide/dexamethasone (Pd) after at least two prior lines of therapy (LoT) (including both V and R) and PVd after at least one prior LoT (including R). The aim of this ongoing, multi-center, non-interventional study is to prospectively collect real world data in patients with RRMM treated with Pd or PVd in Austrian clinical routine practice. **Methods:** Safety (adverse events [AEs]) and efficacy data (objective response rate [ORR]; ≥partial response] were collected from adult patients with RRMM treated with Pd or PVd until progression or unacceptable toxicity; progression-free survival [PFS]) was calculated. Descriptive statistics were used; the study was not powered for direct comparison of cohorts. **Results:** From 09/2014 to 12/2022, 127 patients were enrolled by 9 Austrian centers (126 eligible patients). At inclusion, the median age was 70 years (range 38-90); 33 patients (26%) were >75 years; 65 patients (51%) were male. The median number of prior lines of therapy was 3 (range 1-8). Prior treatments included an immunomodulatory drug (87%), a proteasome inhibitor (92%), an anti-CD38 antibody (18%) and autologous stem cell transplantation (ASCT) (52%). The median number of P treatment cycles was 10 (range 1-90). At cycle 10, 74% of patients still received P at a dose of 4 mg, while only 14% received dexamethasone (dex) at the dose of 40 mg. Safety information was available for 99 patients (78.6%). Out of 651 AEs, 249 (38.2%) were drug related. Most AEs were non-serious (77%); 13.7% required hospitalization, 0.5% were life-threatening and 0.5% were fatal (both not drug related). The most common AEs were neutropenia (21%) and infections (18%). The most common reason for treatment discontinuation was tumor progression (n=73, 58%); death occurred in 6 patients (unrelated to treatment with P (5%); six patients (5%) discontinued treatment due to toxicity. At data cutoff, 16 patients (13%) were still on treatment. The median PFS (months) was 16.4 for all [n=126], 12.8 for Pd [n=50], 22.7 for PVd [n=15] and 32.4 for Pd+additional active substance [Pd+x; n=61].The ORR and CR (both in %) were 64/20 for all [n=114], 49/13 for Pd [n=45], 69/38 for PVd [n=13] and 75/21 for Pd+x [n=56]. **Conclusions:** This interim analysis demonstrates that Pd is an effective and well tolerated treatment in patients with RRMM in clinical practice. Dose reductions of P were less frequent compared to dex (26% vs. 45.6% with dex), suggesting its good tolerability. Presented response data for Pd (PFS: 12.8 months; ORR: 49%) are longer compared to data from earlier, randomized trials (MM-003, NCT01311687). Considering the limitations of noninterventional studies, these results may reflect clinicians' increasing practical experience with Pd and PVd. As indicated by the increase of median PFS, efficacy of Pd may be enhanced by addition of a third antimyeloma agent.

Introduction: Selinexor is a first in class, oral selective inhibitor of nuclear export compound, which inhibits XPO-1 causing accumulation of tumor suppressor proteins in the cellular nucleus leading to apoptosis. It is currently approved for use in patients(pts) with multiple myeloma (MM) and non-Hodgkin's lymphoma. In clinical trials, in combination with other agents, selinexor produced an objective response rate (ORR) ranging from 26% to 78%. In the 'STORM' trial, for pts with triple-class refractory disease, ORR was found to be 26% with a median progression-free survival (PFS) of 3.7 months (mos). We report our single-center experience with the use of selinexor in various combinations in pts with heavily pre-treated

we have found pERP1 to be highly expressed on the surface of MM cell lines in culture and of MM cells from patients in comparison with plasma cells from healthy donors, underscoring the potential of pERP1 as a novel immunotherapy target by using mAb or ADC.

Introduction: Treatment options in patients with RRMM refractory to bortezomib (V) and lenalidomide (R) are limited. Potential approved treatment options include pomalidomide/dexamethasone (Pd) after at least two prior lines of therapy (LoT) (including both V and R) and PVd after at least one prior LoT (including R). The aim of this ongoing, multi-center, non-interventional study is to prospectively collect real world data in patients with RRMM treated with Pd or PVd in Austrian clinical routine practice. **Methods:** Safety (adverse events [AEs]) and efficacy data (objective response rate [ORR]; ≥partial response] were collected from adult patients with RRMM treated with Pd or PVd until progression or unacceptable toxicity; progression-free survival [PFS]) was calculated. Descriptive statistics were used; the study was not powered for direct comparison of cohorts. **Results:** From 09/2014 to 12/2022, 127 patients were enrolled by 9 Austrian centers (126 eligible patients). At inclusion, the median age was 70 years (range 38-90); 33 patients (26%) were >75 years; 65 patients (51%) were male. The median number of prior lines of therapy was 3 (range 1-8). Prior treatments included an immunomodulatory drug (87%), a proteasome inhibitor (92%), an anti-CD38 antibody (18%) and autologous stem cell transplantation (ASCT) (52%). The median number of P treatment cycles was 10 (range 1-90). At cycle 10, 74% of patients still received P at a dose of 4 mg, while only 14% received dexamethasone (dex) at the dose of 40 mg. Safety information was available for 99 patients (78.6%). Out of 651 AEs, 249 (38.2%) were drug related. Most AEs were non-serious (77%); 13.7% required hospitalization, 0.5% were life-threatening and 0.5% were fatal (both not drug related). The most common AEs were neutropenia (21%) and infections (18%). The most common reason for treatment discontinuation was tumor progression (n=73, 58%); death occurred in 6 patients (unrelated to treatment with P (5%); six patients (5%) discontinued treatment due to toxicity. At data cutoff, 16 patients (13%) were still on treatment. The median PFS (months) was 16.4 for all [n=126], 12.8 for Pd [n=50], 22.7 for PVd [n=15] and 32.4 for Pd+additional active substance [Pd+x; n=61].The ORR and CR (both in %) were 64/20 for all [n=114], 49/13 for Pd [n=45], 69/38 for PVd [n=13] and 75/21 for Pd+x [n=56]. **Conclusions:** This interim analysis demonstrates that Pd is an effective and well tolerated treatment in patients with RRMM in clinical practice. Dose reductions of P were less frequent compared to dex (26% vs. 45.6% with dex), suggesting its good tolerability. Presented response data for Pd (PFS: 12.8 months; ORR: 49%) are longer compared to data from earlier, randomized trials (MM-003, NCT01311687). Considering the limitations of noninterventional studies, these results may reflect clinicians' increasing practical experience with Pd and PVd. As indicated by the increase of median PFS, efficacy of Pd may be enhanced by addition of a third antimyeloma agent.

Introduction: Selinexor is a first in class, oral selective inhibitor of nuclear export compound, which inhibits XPO-1 causing accumulation of tumor suppressor proteins in the cellular nucleus leading to apoptosis. It is currently approved for use in patients(pts) with multiple myeloma (MM) and non-Hodgkin's lymphoma. In clinical trials, in combination with other agents, selinexor produced an objective response rate (ORR) ranging from 26% to 78%. In the 'STORM' trial, for pts with triple-class refractory disease, ORR was found to be 26% with a median progression-free survival (PFS) of 3.7 months (mos). We report our single-center experience with the use of selinexor in various combinations in pts with heavily pre-treated

MM. **Methods:** All pts with MM who were treated with selinexor-based combinations were included in the institutional review board approved study. Demographic characteristics, molecular studies, treatment and response information were recorded and included in the study. Survival analysis was performed using the Kaplan-Meir method including PFS and overall survival (OS). The IMWG response criteria were utilized for response assessment. **Results:** We identified 101 pts who were treated consecutively between May 2019 and March 2023 with selinexor-based combinations. 58.4% (n=59) were male, median age was 68.9 years, median time from diagnosis to treatment initiation was 5.9 yrs. Pts had received a median of 4 prior lines of therapies (range 2-13). 85.1% (n=86) were triple class refractory, 97% (n=98) were anti-CD38 refractory. 91.1% (n=92) had received at least 1 autologous stem cell transplant. 67% of the FISH evaluable pts had high risk genetic profiles, defined as those with t(4;14), t(14;16), 17p(-), 1q(+) or t(14;20), 21.7% pts were ISS-3, at diagnosis. Baseline characteristics are summarized in Table 1. Combination agents included pomalidomide (31.6%, n=32), carfilzomib (31.6%, n=32), bortezomib (12.8%, n=13), daratumumab (15.8%, n=16), ixazomib (0.9%, n=1) and dexamethasone (6.9%, n=7). Median starting dose of selinexor was 80 mg (range 40mg to 100mg). Dose reduction for toxicity was necessary in 19 pts (18.8%). The most common reasons for dose reduction were fatigue and thrombocytopenia. Overall response rate (ORR) (partial remission or better) for the entire cohort was 32.7%. The median PFS was 3.0 mos (Graph 1), the median OS was 14.1 mos (Graph 2) and median duration of response (DOR) was 7.8 mos. Median time to best response was 30 days. Efficacy data are summarized in Table 1 **Conclusions:** In our single-center experience, selinexor-based combinations were overall well tolerated, with few pts needing dose modifications. Similar to the real-world outcomes reported by Kastritis et al., a low response rate was observed in our larger cohort of pts with the use of selinexor in several combinations. However, clinical benefit with a moderate duration of response was observed.

Uninvolved hypogammaglobulinemia was not a predictor of the infection risk in anti-CD38 chemotherapy

Firas Al-Kaisi[1], Sofia Kazmi[1], Michael Acquah[1]

[1]The Royal Derby Hospital

Introduction: Infections are major causes of morbidity with myeloma treatment. Anti-CD38 antibodies are important additions to myeloma chemotherapy. Through their effect on normal plasma cells, they can reduce the levels of uninvolved immunoglobulins (Ig). We sought to investigate if there was any relationship between the changes in the uninvolved Ig levels during anti-CD38 therapy and the risk of developing infections. We also compared the levels of Ig across different anti-CD38 therapies at different time points. **Methods:** This is a retrospective single-centre analysis of myeloma patients treated with anti-CD38 therapy (single agent or in combination). The levels of the uninvolved Ig and lymphocytes were recorded at baseline and at three-monthly intervals in addition to the number of infections requiring inpatient treatment for up to 18 chemotherapy cycles. Patients who had less than 3 months of treatment and those in the induction phase were excluded. **Results:** Between March 2018 and March 2023, 108 patients were treated with Isatuximab-Pomalidomide-Dexamethasone (IPD), Daratumumab-Bortezomib-Dexamethasone (DVd) and Daratumumab monotherapy (n=28, 49 and 32 respectively). The median age at the start of treatment was 73 (range 41 to 90). The median number of treatment cycles was 11 (range 3 to 45). Thirty-two patients (29%) had at least one infective episode requiring hospitalisation during the course of treatment. Of those, 25% had Daratumumab monotherapy and the rest were equally divided between the IPD and the DVd groups (37.5% each). The median uninvolved Ig levels were subnormal at all the time points assessed within the three regimens. There was no significant change in the uninvolved IgG and IgM levels in the infected group at all time points. The non-infected group showed a significant drop in the uninvolved IgM and IgG levels at the 3 and 6-month time points after which the levels were not significantly different from the baseline. There was a significant drop in the uninvolved IgA levels which persisted at all the time points in both the infected and the non-infected groups. The lymphocyte count changes were not significant in both groups at all time points. The analysis of the uninvolved Ig changes subgrouped by the treatment regimen showed a significant and maintained drop in the IgA levels with Daratumumab monotherapy and DVd and a significant drop in the IgM levels at the early time points with DVd. Comparing the levels of the Ig isotypes across regimens revealed no significant changes attributable to the underlying chemotherapy treatment. **Conclusions:** Uninvolved hypogammaglobulinemia was universal with various anti-CD38 regimens but did not predict infection risk. Uninvolved Ig reduction was most pronounced with IgA but did not correlate with the development of infections. We conclude that the uninvolved hypogammaglobulinemia is a poor predictor of the infection risk with anti-CD38 therapy.

Introduction: Infections are major causes of morbidity with myeloma treatment. Anti-CD38 antibodies are important additions to myeloma chemotherapy. Through their effect on normal plasma cells, they can reduce the levels of uninvolved immunoglobulins (Ig). We sought to investigate if there was any relationship between the changes in the uninvolved Ig levels during anti-CD38 therapy and the risk of developing infections. We also compared the levels of Ig across different anti-CD38 therapies at different time points. **Methods:** This is a retrospective single-centre analysis of myeloma patients treated with anti-CD38 therapy (single agent or in combination). The levels of the uninvolved Ig and lymphocytes were recorded at baseline and at three-monthly intervals in addition to the number of infections requiring inpatient treatment for up to 18 chemotherapy cycles. Patients who had less than 3 months of treatment and those in the induction phase were excluded. **Results:** Between March 2018 and March 2023, 108 patients were treated with Isatuximab-Pomalidomide-Dexamethasone (IPD), Daratumumab-Bortezomib-Dexamethasone (DVd) and Daratumumab monotherapy (n=28, 49 and 32 respectively). The median age at the start of treatment was 73 (range 41 to 90). The median number of treatment cycles was 11 (range 3 to 45). Thirty-two patients (29%) had at least one infective episode requiring hospitalisation during the course of treatment. Of those, 25% had Daratumumab monotherapy and the rest were equally divided between the IPD and the DVd groups (37.5% each). The median uninvolved Ig levels were subnormal at all the time points assessed within the three regimens. There was no significant change in the uninvolved IgG and IgM levels in the infected group at all time points. The non-infected group showed a significant drop in the uninvolved IgM and IgG levels at the 3 and 6-month time points after which the levels were not significantly different from the baseline. There was a significant drop in the uninvolved IgA levels which persisted at all the time points in both the infected and the non-infected groups. The lymphocyte count changes were not significant in both groups at all time points. The analysis of the uninvolved Ig changes subgrouped by the treatment regimen showed a significant and maintained drop in the IgA levels with Daratumumab monotherapy and DVd and a significant drop in the IgM levels at the early time points with DVd. Comparing the levels of the Ig isotypes across regimens revealed no significant changes attributable to the underlying chemotherapy treatment. **Conclusions:** Uninvolved hypogammaglobulinemia was universal with various anti-CD38 regimens but did not predict infection risk. Uninvolved Ig reduction was most pronounced with IgA but did not correlate with the development of infections. We conclude that the uninvolved hypogammaglobulinemia is a poor predictor of the infection risk with anti-CD38 therapy.

Safety and clinical activity of belantamab mafodotin combined with carfilzomib, lenalidomide, and dexamethasone after at least one prior line of therapy, interim results from phase 1 clinical trial

Shebli Atrash[1], James Symanowski[1], Barry Paul[1], Cindy Varga[1], Xhevahire Begic[1], Sarah Norek[1], Manisha Bhutani[2], Peter Voorhees[3]

[1]Levine Cancer Institute; [2]Division of Plasma Cell Disorders, Department of Hematologic Oncology & Blood Disorders, Levine Cancer Institute, Atrium Health, Charlotte, NC, USA; [3]Levine Cancer Institute-Atrium Health Wake Forest University School of Medicine

Introduction: Belantamab mafodotin (BM) is a novel BCMA-targeted antibody-drug conjugate that showed promising efficacy in relapsed/refractory multiple myeloma (RRMM) patients (pts), with an overall response rate (ORR) of 32% and median duration of response (DOR) of 11 months when dosed at 2.5 mg/kg q3 weeks—however, 27% of pts suffered from G3 keratopathy.

Preliminary clinical data support the use of BM with a proteasome inhibitor and IMiD-based therapy. To capitalize on the efficacy of BM and decrease keratopathy, we conducted a phase 1/2 clinical trial evaluating lower doses of BM administered q8 weeks in combination with the KRd backbone for pts with early relapse of MM. **Methods:** Pts with RRMM after 1-3 prior lines of therapy (LOT) were enrolled in a phase 1 trial with a 3+3 dose escalation followed by an expansion cohort to better inform the recommended phase II dose (RP2D). The primary objective for the phase 1 portion of the trial was to establish the maximum tolerated dose (MTD) of BM when given with KRd as determined by dose-limiting toxicities (DLTs) in cycle 1. Secondary objectives included ORR, depth of response, DOR, progression-free survival, overall survival, and safety. Two doses of BM were tested: 1.4 mg/kg and 1.9 mg/kg given IV over 30 – 60 minutes every 8 weeks with KRd (K 20/56 mg/m^2 days 1,8,15; R 25 mg po days1-21; and d 20/40 mg po weekly) in 28-day cycles for up to 18 cycles followed by R maintenance. **Results:** With a data cutoff of March 6, 2023, 11 pts were enrolled, 6 pts at 1.4 mg/kg and 5 pts at 1.9 mg/kg. 63.6% of pts were male, 45.5% black, and 18% had high-risk cytogenetics and 64% including 1q gain. 91% were refractory to a maintenance dose of R, all were bortezomib exposed, and 27% were daratumumab refractory. The median LOT was 1 (range 1-3). All 11 enrolled pts were DLT evaluable. At the 1.4 mg/kg dose level, one DLT of grade 4 thrombocytopenia was reported out of 6 pts. No DLTs were reported among the pts enrolled at the 1.9 mg/kg dose level (including a 6th pt treated after data cutoff). The most common adverse events were non-specified eye disorders (81.1%), blurred vision (63.6%), hypokalemia (63.6%), diarrhea (63.6%), fatigue (63.6%), constipation (45.5%), and pain (45.5%). Four pts experienced G3 keratopathy, and the median time to recovery was 25 days (range 8-29 days). All pts achieved at least a PR, the VGPR(+) rate was 73%, and the CR(+) rate was 45%. With a median follow-up of 9.2 months, only one pt has progressed with extramedullary liver disease. The remainders are alive without disease progression. **Conclusions:** The dose escalation portion of the phase 1 trial has established a BM dose of 1.9 mg/kg given q8 weeks in combination with KRd as the MTD. Keratopathy was common but of slower onset and associated with less severe, high-grade subjective symptoms relative to what is seen with 2.5 mg/kg dosing given q3 weeks. Enrollment into the expansion cohort to better inform the RP2D is ongoing, and updated data will be presented at the meeting.

Safety and clinical activity of ruxolitinib combined with carfilzomib and dexamethasone for patients with carfilzomib-refractory multiple myeloma: results from a phase 1 clinical trial

Shebli Atrash[1], James Symanowski[1], Sarah Norek[1], Xhevahire Begic[1], Manisha Bhutani[2], Barry Paul[1], Cindy Varga[1], Andrew Kin[3], Jeffrey[3], Peter Voorhees[4], Saad Usmani[5]

[1]Levine Cancer Institute; [2]Division of Plasma Cell Disorders, Department of Hematologic Oncology & Blood Disorders, Levine Cancer Institute, Atrium Health, Charlotte, NC, USA; [3]Karmanos Cancer Institute, Detroit, MI, USA; [4]Levine Cancer Institute-Atrium Health Wake Forest University School of Medicine; [5]Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: Ruxolitinib (Rux) is a selective Janus kinase 1/2 inhibitor approved for the treatment of patients with polycythemia vera, myelofibrosis, and refractory Graft-versus-host disease. Preclinical studies showed Rux could block the expression of MUC1 and inhibit the STAT pathway leading to modulation of IL-6-mediated myeloma cell refractoriness and reverse checkpoint inhibition by downregulating PD-L1 and PD-L2 expression on both myeloma and stromal cells (Chen et al. 2019). We conducted a phase 1 trial to determine the safety and preliminary efficacy of Rux in combination with carfilzomib for patients with carfilzomib-refractory, relapsed/refractory multiple myeloma. **Methods:** A 3+3 dose escalation design was used for dose escalation. Patients received oral Rux twice daily continuously at three doses across three cohorts (5mg, 10 mg, and 15 mg) in addition to carfilzomib 20/56 mg/m^2 on days 1,2,8,9,15,16; and dexamethasone 40 mg po days 1,8,15; in 28-day cycles. The primary objective was to identify the maximum tolerated dose as defined by the emergence of dose limiting toxicities during cycle 1 of therapy. Secondary objectives included response rate, depth of response, progression-free survival, overall survival and safety. Patients were enrolled from Jan/2019 to Dec/2022. The study accrual was placed on hold during 2020-2021 due to the COVID19 pandemic related institutional resource constraints. **Results:** As of the data cutoff date of March 6, 2023, a total of 12 patients were enrolled. The median follow up time was 42.2 months. The median age for the enrolled population was 66 years, female 25%, high-risk cytogenetics 42%, all subjects were IMiD refractory, CD38 refractory 83%. The median lines of prior therapies were 5. Eight patients were dose-limiting toxicity evaluable and dose escalation occurred from the 5mg cohort (0 DLTs out of 3 subjects) and from the 10mg cohort (0 DLTs out of 3 subject). In the 15mg cohort, one DLT occurred out of 2 subjects. The most common adverse events were anemia (83%), decreased platelet count (50%), dyspnea (50%), and increased creatinine (41.7%). TEAEs by maximum severity grade occurring in at least 25% of subjects are shown in Table 1. The best response observed in this trial was a VGPR in one subject. The overall response rate was 25%. The median progression-free survival time was 3.2 months, and the overall survival time was 15.8 months. The study was terminated early due to withdrawal of sponsor funding for not meeting accrual goals during the COVID19 pandemic. **Conclusions:** Ruxolitinib may have an acceptable safety profile in combination with carfilzomib at a dose of 10 mg po bid. Despite early encouraging data with 15 mg, the trial could not conclude the safety of this dose. In this proof-of-principle trial, ruxolitinib may have the potential to overcome refractoriness to carfilzomib. However, more studies are needed.

Preliminary clinical data support the use of BM with a proteasome inhibitor and IMiD-based therapy. Use of cilta-cel CAR T cells following previous use of a BCMA-directed CAR T-cell product in heavily treated patients with relapsed/refractory multiple myeloma: a single institution case series

Narsis Attar[1], Diana Cirstea[2], Andrew Branagan[2], Andrew Yee[2], Matthew Frigault[2], Noopur Raje[2]

[1]Dana Farber Cancer Institute/MGH cancer center; [2]Massachusetts General Hospital Cancer Center

Introduction: BCMA-directed CAR T-cell (CAR T) therapy has demonstrated remarkable efficacy in patients with relapsed/refractory multiple myeloma (rrMM). Pivotal trials such as the KarMMa and CARTITUDE studies using ide-cel and cilta-cel, respectively, have shown ORR of 73% and 98%, leading to FDA approval of these products. Notably, ide-cel conferred a median OS of 19.4 months with a median DOR of 10.7 months. Similarly, cilta-cel conferred 27-month PFS and OS rates of 55% and 70.4%, respectively. Although these and real-world outcomes are promising, relapse after BCMA CAR T therapy remains a challenge. **Methods:** This is a case series of 5 patients with rrMM from a single institution treated with BCMA-directed CAR T therapy between 2019-2022, followed by a second BCMA-directed CAR T therapy using cilta-cel at the time of relapse. Here we report the response and toxicity profile following the second CAR T therapy. **Results:** Patients had a median age of 64 (40-76). 2 out of 5 patients had high risk disease based on cytogenetics. Prior to the second CAR T therapy, patients had received a median of 7 (5-8) lines of treatment including the first CAR T therapy. For the first CAR T therapy, 3 patients received an investigational BCMA-directed CAR T therapy at the recommended doses of the product and 2 patients received ide-cel. At the time of subsequent relapse all patients eventually received a second CAR T therapy with cilta-cel. ORR to first CAR T-cell therapy was 80%; 4 patients achieved ≥ VGPR (n=2 VGPR; n= 2 sCR), and 1 patient had PD, with a median DOR of 16 months (7-22 months) for responders. The time between two CAR T therapies ranged from 8-38 months, with all patients receiving at least 1 and up to 2 lines of treatment including bridging therapy before cilta-cel. At the time of this report, with a follow up ranging from 3.1-11 months after the second CAR T therapy, 4 out of 5 patients had achieved a response (n=3 CR; n=1 PR). One patient had refractory disease and required subsequent treatment. Notably, this was the same patient who had progressed on the previous CAR T cell therapy. Grade 2 CRS after cilta-cel was seen in 1 out of 5 patients. Hematologic toxicities were seen in all patients with grade 3-4 neutropenia in 5, grade 3 anemia in 3 and grade 4 thrombocytopenia in 2 patients. Prolonged grade 3-4 thrombocytopenia was seen in 1 responder requiring transfusions and thrombopoietin analogs. Three out of 4 responders had hypogammaglobulinemia with levels recovering in 2 patients within 8-12 weeks. One patient had prolonged hypogammaglobulinemia requiring IVIG beyond this time point. **Conclusions:** This case series demonstrates the early efficacy and safety of a second BCMA-directed CAR T therapy, specifically in patients previously responsive to similar BCMA-directed therapy. This highlights the need to better understand the clinical utility of this approach and to delineate the heterogenous disease course and mechanism of resistance post BCMA CAR T therapy.

P-229

Exposure-response analysis of venetoclax in combination with carfilzomib and dexamethasone in t(11;14)-positive relapsed/refractory multiple myeloma patients

Mohamed Badawi[1], Benjamin Engelhardt[1], Edyta Dobkowska[2], Rong Deng[3], Jonathan Kaufman[4], Rajeev Menon[1], Ahmed Hamed Salem[1]

[1]AbbVie Inc.; [2]Pharmacyclics Switzerland GmbH, an AbbVie Company, Schaffhausen, Switzerland; [3]Genentech Inc.; [4]Winship Cancer Institute of Emory University, Atlanta, GA, USA

Introduction: Venetoclax is a first in class, selective BCL2 inhibitor that has gained approval for the treatment of CLL and AML and is currently being evaluated in other hematological indications including multiple myeloma (MM). This analysis aimed to characterize the exposure-response relationship of venetoclax (Ven) when administered in combination with carfilzomib and dexamethasone (Kd) in the biomarker selected, t(11;14)-positive relapsed/refractory MM patients. **Methods:** 55 subjects enrolled in Study NCI: NCT02899052 (37 receiving VenKd and 18 in the control arm receiving Kd) were included in the analysis. A population pharmacokinetic model was developed, and individual post hoc empirical Bayes parameter estimates were used to derive individual subject venetoclax exposures (average area under the concentration time curve to the time of event [AUCavg] and steady state AUC [AUCss]). Quartile plots and logistic regression models were used to evaluate the exposure-efficacy and exposure-safety relationships of venetoclax. Efficacy endpoints assessed included clinical response of overall response rate (ORR), very good partial response or better (≥VGPR) rate and complete response or better (≥CR) rate. Safety endpoints evaluated included Grade ≥3 neutropenia, Grade ≥3 infections, Grade ≥3 treatment emergent adverse events and any grade serious treatment-emergent adverse events. **Results:** Quartile plots demonstrated that compared to the control arm (Kd), adding venetoclax resulted in higher OR, ≥VGPR and ≥CR rates. Within the VenKd treatment arms, a flat exposure-response relationship for Ven was observed for all efficacy endpoints (ORR, ≥VGPR and ≥CR rates) suggesting that efficacy is maximized, and higher venetoclax exposures may not be associated with improved efficacy compared to lower exposures at the studied dose range of 400-800 mg. Both 400 mg and 800 mg venetoclax were generally tolerated, however exposure-safety analysis demonstrated that higher venetoclax exposures (associated with 800 mg venetoclax) trended with higher rates of Grade ≥3 neutropenia. Higher venetoclax exposures were not associated with higher rates of Grade ≥3 infections, Grade ≥3 treatment-emergent adverse events, or serious treatment-emergent adverse events (any grade). Study is ongoing and enrolling subjects; more mature data may be presented at the congress. **Conclusions:** Exposure-response analyses confirm the benefit of adding venetoclax at 400-800 mg doses to carfilzomib and dexamethasone and support

Introduction: Nearly all patients (pts) with multiple myeloma (MM) receive lenalidomide (LEN) in first or second line of treatment (tx; LoT). Pts with RRMM who have exhausted LEN benefits need improved options. The phase 2 MM-014 trial (NCT01946477) explored pomalidomide (POM)-based tx in early LoT for RRMM in 3 cohorts. In cohort B, at a median follow-up of 28.4mo, POM+daratumumab (DARA)+low-dose dexamethasone (DEX; DPd) showed promising efficacy, with an overall response rate (ORR) of 77.7% and median progression-free survival of 30.8mo (Bahlis, Leuk Lymphoma 2022). Here, we report the final overall survival (OS) in this cohort. **Methods:** In cohort B, pts aged ≥18y with RRMM who had received 1–2 prior LoT with LEN-based regimen as their most recent were eligible. Pts received DPd in 28-d cycles (C): POM 4mg orally on d1–21; DEX 40mg (age ≤75y) or 20mg (age >75y) orally on d1, 8, 15, 22; DARA intravenously 16 mg/kg bodyweight on d1, 8, 15, 22 of C1–2, d1, 5 of C3–6, and d1 of C7 and beyond. ORR was the primary endpoint; OS and safety were secondary endpoints. OS was defined as time from tx start to time of death from any cause; pts were censored at date last known to be alive. Dose interruptions and reductions were allowed for certain tx-emergent adverse events (TEAEs). Pts were followed for OS, subsequent tx, and second primary malignancies for ≤5y after last pt was enrolled. **Results:** Among 112 pts enrolled, 85 (75.9%) had LEN-refractory disease and 27 (24.1%) had LEN-relapsed disease; 69 (61.6%) and 43 (38.4%) received 1 and 2 prior LoT, respectively. At a median (range) follow-up of 41.9 (0.4–73.1) mo, 96 (85.7%) pts had discontinued tx, 54 (48.2%) due to progressive disease (PD). Pts received POM, DEX, and DARA for median (range) durations of 15.7 (0.3–73.1), 13.7 (< 0.1–72.5), and 15.2 (< 0.1–72.7) mo, respectively. Fifty (44.6%) pts died, mostly due to PD (n=28 [25.0%]). Median (95% CI) OS was 56.7 mo (46.5–not reached [NR]): 53.6 mo (28.6–NR) and NR (47.6–NR) for pts who had LEN-refractory and LEN-relapsed disease, respectively. TEAEs leading to POM, DEX, or DARA discontinuation occurred in 7 (6.3%), 9 (8.0%), and 6 (5.4%) pts, respectively. Tx-related TEAEs led to POM and DEX reduction in 31 (27.7%) and 38 (33.9%) pts, respectively; and led to POM, DEX, and DARA interruption in 55 (49.1%), 17 (15.2%), and 65 (58.0%) pts, respectively. Neutropenia was the most common tx-related TEAE leading to dose modification of POM (reduction, n=17 [15.2%]; interruption, n=38 [33.9%]) and DARA (interruption, n=30 [26.8%]); insomnia was the most common tx-related TEAE leading to DEX dose modification (reduction, n=10 [8.9%]; interruption, n=1 [0.9%]). **Conclusions:** With long-term follow-up, pts with RRMM treated with DPd showed favorable OS. The DPd safety profile was similar to previous reports, with no new safety signals identified. These data suggest that DPd is beneficial for pts with RRMM who have exhausted benefits of LEN. Introduction: Multiple myeloma (MM) is characterized by malignant plasma cell accumulation in the bone marrow. Despite use of emerging therapies, patients ultimately relapse with drug-resistant disease; overall survival with triple-refractory disease is 6–13 months. ABBV-383 is a fully human bispecific antibody that targets both B-cell maturation antigen (BCMA), a highly expressed protein on the surface of MM cells, and CD3 on the surface of T-cells. This dual-binding results in T-cell activation and selective destruction of BCMA-positive MM cells. Phase 1 results in patients with triple-class exposed relapsed/refractory MM (RRMM) showed ABBV-383 was well-tolerated with an overall response rate of 63%. Cytokine release syndrome (CRS) occurred in 57% of patients; these were mostly single Grade 1/2 events with median time of 1 day (after first

continued evaluation of the VenKd combination in the biomarker selected t(11;14)-positive relapsed/refractory MM population.

ABBV-383, a BCMA-CD3 bispecific antibody, in relapsed/refractory multiple myeloma: a multicenter, phase 1b dose optimization study with step-up dosing

Muhamed Baljevic[1], Hila Magen[2], Emma Searle[3], Ziyi Jin[4], Elise Strange[4], Anders Svensson[4], Shaji Kumar[5]

[1]Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center; [2]Chaim Sheba Medical Center, Ramat-Gan, Sackler Faculty of Medicine, Tel Aviv University, Israel; [3]The Christie Hospital NHS Foundation Trust and The University of Manchester, Manchester; [4]AbbVie, Inc; [5]Mayo Clinic, Rochester, MN, US

Introduction: Multiple myeloma (MM) is characterized by malignant plasma cell accumulation in the bone marrow. Despite use of emerging therapies, patients ultimately relapse with drug-resistant disease; overall survival with triple-refractory disease is 6–13 months. ABBV-383 is a fully human bispecific antibody that targets both B-cell maturation antigen (BCMA), a highly expressed protein on the surface of MM cells, and CD3 on the surface of T-cells. This dual-binding results in T-cell activation and selective destruction of BCMA-positive MM cells. Phase 1 results in patients with triple-class exposed relapsed/refractory MM (RRMM) showed ABBV-383 was well-tolerated with an overall response rate of 63%. Cytokine release syndrome (CRS) occurred in 57% of patients; these were mostly single Grade 1/2 events with median time of 1 day (after first

dose of ABBV-383) to both onset and to resolution; no events were life-threatening or fatal. Neutropenia (37%) and anemia (29%) were the most common hematological AEs. Step-up dosing strategies, where a lower initial dose is given prior to the full dose, have been effectively utilized for other T-cell targeting therapeutics in myeloma as well as other diseases to lower the risk of severe CRS. The intent with this Phase 1b trial, which is currently enrolling, is to evaluate step-up dosing of ABBV-383 in Cycle 1 as a mitigation strategy for CRS. **Methods:** The primary objective is to assess frequency and severity of CRS in patients with RRMM treated with ABBV-383 monotherapy with step-up dosing. Primary and secondary endpoints are Grade ≥2 CRS during Cycle 1 and any CRS during the study, respectively. Secondary objectives are to assess safety and tolerability of ABBV-383 in these patients. Exploratory efficacy endpoints are clinical activity as defined by IMWG 2016 criteria, including objective response rates, time to response, duration of response, and progression-free survival. Eligible patients are aged ≥18 years with ECOG status 0–2 and RRMM with documented progression after last treatment. Patients must be BCMA-targeted therapy-naïve and have received ≥3 lines of therapy, including a proteasome inhibitor, an immunomodulatory drug, and an anti-CD38 monoclonal antibody. The study consists of 2 phases: step-up dose optimization and dose expansion. In the dose optimization phase, patients receive the step-up dose on Day 1 of treatment Cycle 1 and the target dose on Day 4 of Cycle 1. In Cycle 2 and all subsequent cycles, patients receive the target dose on Day 1. Therapy continues until disease progression, withdrawal, or discontinuation. Patients are hospitalized for 24 hours during both step-up and target dosing in Cycle 1. In the dose expansion phase, patients will receive the optimum step-up dose on Day 1 and the target dose on Day 4 of Cycle 1. Patients receive the target dose on Day 1 of subsequent cycles. This trial is currently enrolling at 34 sites in 7 countries: US, Canada, Denmark, France, Israel, Spain, and the UK.

Effectiveness of anti-B-cell maturation antigen (BCMA)-targeting therapy after selinexor treatment

Muhamed Baljevic[1], Philippe Moreau[2], Sascha Tuchman[3], Natalie Callander[4], Suzanne Lentzsch[5], Dane Van Domelen[6], Ohad Benture[6], Jorge Monge[7], Noa Biran[8]

[1]Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center; [2]University Hospital Hôtel-Dieu, Nantes, France; [3]University of North Carolina – Chapel Hill Comprehensive Cancer Center; [4]University of Wisconsin; [5]Columbia University Medical Center, New York, NY, USA; [6]Karyopharm; [7]Weill Cornell Medicine Myeloma Center; [8]Hackensack University Medical Center, Hackensack, NJ, USA

Introduction: Multiple myeloma (MM) remains incurable, with the disease typically becoming refractory to three main classes of standard therapies: immunomodulatory drugs (IMiDs), proteasome inhibitors (PIs) and anti-CD38 monoclonal antibodies (αCD38 mAbs). Treatments with novel mechanisms of action, including the XPO1 inhibitor selinexor and T-cell engaging anti-B-cell maturation antigen (αBCMA)-agents (antibody drug conjugates [ADC], bi-specific antibodies [BiS]), are increasingly used for treatment of relapsed and/or refractory MM (RRMM) after standard therapies have failed. Emerging data suggests a deleterious impact on T cell function with certain MM treatments, including alkylators and PIs, leading to inferior clinical outcomes. The influence of selinexor-based treatment on T cell function, which may alter the efficacy of αBCMA agents following selinexor treatment, is unknown. **Methods:** We analyzed the effectiveness of non-cellular αBCMA (NCA) therapies in pts with MM treated in 4 clinical studies (STORM [NCT02336815]; STOMP [NCT02343042]; BOSTON [NCT03110562], XPORT-MM-028 [NCT04414475]) with selinexor + dexamethasone (Xd), with or without PIs, IMiDs, or αCD38 mAbs, followed by therapy with NCA. After end of treatment with selinexor, survival follow-up data was collected every 3 months for 1 (STORM, STOMP, XPORT-MM-028) to 5 years (BOSTON). **Results:** Across the 4 clinical studies, 724 pts received selinexor, 404 of which had therapy post-selinexor documented. Thirty-seven pts (median age: 68, range: 40-87) received NCA therapy at any time following a selinexor regimen (Xd, n=12; Xd + bortezomib, n=9; Xd + pomalidomide, n=6; Xd + daratumumab, n=3; Xd + carfilzomib, n=5; Xd + ixazomib, n=2). NCAs included the ADC belantamab mafodotin (n=28), the BiS teclistamab (n=2), SEA-BCMA (n=2), AMG 701 (n=1), elranatamab (n=1), MEDI2228 (n=1), and investigational (n=3; 2 had αBCMA bispecific antibodies and 1 had αBCMA BITE) (1 pt received 2 NCAs, belantamab and teclistamab). For the selinexor-based regimens, the median number of previous lines of therapy was 5 (range: 2-11) and 21 (56.8%) pts had triple-class refractory MM including 8 (21.6%) with penta-refractory MM. Median time from last dose of selinexor to NCA was 8 weeks (range: 2-117). Median time to treatment discontinuation with NCA was 4.4 months (95% CI: 2.1, NE). The median overall survival from initiation of NCA was 12.0 months (95% CI: 9.4, NE) with a median follow-up of 7.8 months. **Conclusions:** In this cohort of heavily-pretreated pts with MM who received a selinexor regimen prior to NCA, overall survival was in the range of 1 year, akin to historical results seen with ADCs. The 8-week median time between administration of selinexor and NCAs suggests that selinexor, with various partner agents, did not negatively impact overall survival with subsequent NCA therapy.

The influence of selinexor-based treatment on T cell function, which may alter the efficacy of αBCMA agents following selinexor treatment, is unknown. **Methods:** We analyzed the effectiveness of non-cellular αBCMA (NCA) therapies in pts with MM treated in 4 clinical studies (STORM [NCT02336815]; STOMP [NCT02343042]; BOSTON [NCT03110562], XPORT-MM-028 [NCT04414475]) with selinexor + dexamethasone (Xd), with or without PIs, IMiDs, or αCD38 mAbs, followed by therapy with NCA. After end of treatment with selinexor, survival follow-up data was collected every 3 months for 1 (STORM, STOMP, XPORT-MM-028) to 5 years (BOSTON). **Results:** Across the 4 clinical studies, 724 pts received selinexor, 404 of which had therapy post-selinexor documented. Thirty-seven pts (median age: 68, range: 40-87) received NCA therapy at any time following a selinexor regimen (Xd, n=12; Xd + bortezomib, n=9; Xd + pomalidomide, n=6; Xd + daratumumab, n=3; Xd + carfilzomib, n=5; Xd + ixazomib, n=2). NCAs included the ADC belantamab mafodotin (n=28), the BiS teclistamab (n=2), SEA-BCMA (n=2), AMG 701 (n=1), elranatamab (n=1), MEDI2228 (n=1), and investigational (n=3; 2 had αBCMA bispecific antibodies and 1 had αBCMA BITE) (1 pt received 2 NCAs, belantamab and teclistamab). For the selinexor-based regimens, the median number of previous lines of therapy was 5 (range: 2-11) and 21 (56.8%) pts had triple-class refractory MM including 8 (21.6%) with penta-refractory MM. Median time from last dose of selinexor to NCA was 8 weeks (range: 2-117). Median time to treatment discontinuation with NCA was 4.4 months (95% CI: 2.1, NE). The median overall survival from initiation of NCA was 12.0 months (95% CI: 9.4, NE) with a median follow-up of 7.8 months. **Conclusions:** In this cohort of heavily-pretreated pts with MM who received a selinexor regimen prior to NCA, overall survival was in the range of 1 year, akin to historical results seen with ADCs. The 8-week median time between administration of selinexor and NCAs suggests that selinexor, with various partner agents, did not negatively impact overall survival with subsequent NCA therapy.

dose of ABBV-383) to both onset and to resolution; no events were life-threatening or fatal. Neutropenia (37%) and anemia (29%) were the most common hematological AEs. Step-up dosing strategies, where a lower initial dose is given prior to the full dose, have been effectively utilized for other T-cell targeting therapeutics in myeloma as well as other diseases to lower the risk of severe CRS. The intent with this Phase 1b trial, which is currently enrolling, is to evaluate step-up dosing of ABBV-383 in Cycle 1 as a mitigation strategy for CRS. **Methods:** The primary objective is to assess frequency and severity of CRS in patients with RRMM treated with ABBV-383 monotherapy with step-up dosing. Primary and secondary endpoints are Grade ≥2 CRS during Cycle 1 and any CRS during the study, respectively. Secondary objectives are to assess safety and tolerability of ABBV-383 in these patients. Exploratory efficacy endpoints are clinical activity as defined by IMWG 2016 criteria, including objective response rates, time to response, duration of response, and progression-free survival. Eligible patients are aged ≥18 years with ECOG status 0–2 and RRMM with documented progression after last treatment. Patients must be BCMA-targeted therapy-naïve and have received ≥3 lines of therapy, including a proteasome inhibitor, an immunomodulatory drug, and an anti-CD38 monoclonal antibody. The study consists of 2 phases: step-up dose optimization and dose expansion. In the dose optimization phase, patients receive the step-up dose on Day 1 of treatment Cycle 1 and the target dose on Day 4 of Cycle 1. In Cycle 2 and all subsequent cycles, patients receive the target dose on Day 1. Therapy continues until disease progression, withdrawal, or discontinuation. Patients are hospitalized for 24 hours during both step-up and target dosing in Cycle 1. In the dose expansion phase, patients will receive the optimum step-up dose on Day 1 and the target dose on Day 4 of Cycle 1. Patients receive the target dose on Day 1 of subsequent cycles. This trial is currently enrolling at 34 sites in 7 countries: US, Canada, Denmark, France, Israel, Spain, and the UK.

Effectiveness of anti-B-cell maturation antigen (BCMA)-targeting therapy after selinexor treatment

Muhamed Baljevic[1], Philippe Moreau[2], Sascha Tuchman[3], Natalie Callander[4], Suzanne Lentzsch[5], Dane Van Domelen[6], Ohad Benture[6], Jorge Monge[7], Noa Biran[8]

[1]Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center; [2]University Hospital Hôtel-Dieu, Nantes, France; [3]University of North Carolina – Chapel Hill Comprehensive Cancer Center; [4]University of Wisconsin; [5]Columbia University Medical Center, New York, NY, USA; [6]Karyopharm; [7]Weill Cornell Medicine Myeloma Center; [8]Hackensack University Medical Center, Hackensack, NJ, USA

Introduction: Multiple myeloma (MM) remains incurable, with the disease typically becoming refractory to three main classes of standard therapies: immunomodulatory drugs (IMiDs), proteasome inhibitors (PIs) and anti-CD38 monoclonal antibodies (αCD38 mAbs). Treatments with novel mechanisms of action, including the XPO1 inhibitor selinexor and T-cell engaging anti-B-cell maturation antigen (αBCMA)-agents (antibody drug conjugates [ADC], bi-specific antibodies [BiS]), are increasingly used for treatment of relapsed and/or refractory MM (RRMM) after standard therapies have failed. Emerging data suggests a deleterious impact on T cell function with certain MM treatments, including alkylators and PIs, leading to inferior clinical outcomes. The influence of selinexor-based treatment on T cell function, which may alter the efficacy of αBCMA agents following selinexor treatment, is unknown. **Methods:** We analyzed the effectiveness of non-cellular αBCMA (NCA) therapies in pts with MM treated in 4 clinical studies (STORM [NCT02336815]; STOMP [NCT02343042]; BOSTON [NCT03110562], XPORT-MM-028 [NCT04414475]) with selinexor + dexamethasone (Xd), with or without PIs, IMiDs, or αCD38 mAbs, followed by therapy with NCA. Physician perspectives regarding conventional marrow testing and MRD assessments to guide decision-making in myeloma

Rahul Banerjee[1], Faiza Zafar[2], Nate Way[3], Kushal Modi[3], Sean Carey[3], Emily Mulvihill[3], Allicia Girvan[4], Seema Tulsian[4], Sophia Li[2]

[1]Division of Medical Oncology, University of Washington; [2]Genentech, Inc., South San Francisco, CA, US; [3]Cerner Enviza, an Oracle Company; [4]AbbVie, Inc. North Chicago, IL, US

Introduction: Background: Decision-making in multiple myeloma (MM) is complex as there are numerous treatment options available across multiple lines of therapy. A recent survey suggested many MM physicians are interested in MRD-guided decision making (Derman et al., 2022). We thus conducted an online survey to investigate physicians' attitudes toward MRD assessments and conventional marrow testing (e.g., FISH or karyotyping) and how these tests modify treatment selection. **Methods:** Methods: Board-certified hematologists and/or oncologists (N=75) who had ≥10 patients with MM, spent ≥50% of time in clinical practice in the US, and had been in clinical practice for at least two years completed an online survey. Descriptive statistics assessed practice characteristics, testing procedures, and attitudinal items. **Results:** Results: Most physicians practiced in a community setting (69%) with a substantial number of MM patients under their care (M=60.5, SD=57.1, Mdn=40.0, IQR 25-75). Most physicians routinely ordered bone marrow karyotyping or FISH (M=77.8%, SD=33.0, Mdn=100.0%, IQR 50-100%), while a significant minority routinely ordered MRD assessments (M=41.3%, SD=36.9, Mdn=30.0%, IQR 10-80%). Among cases where such tests were ordered, physicians chose or modified treatment based on the results of karyotyping/FISH half the time (M=53.3%, SD=37.5, Mdn=50.0%, IQR 23-100%) and chose or modified treatment based on the results of MRD assessments only a third of the time (M=39.4%, SD=32.5, Mdn=30.0%, IQR 10-60%). On an agreement scale anchored at 1 (prefer personalized treatment approaches) versus 5 (prefer standard treatment approaches that consistently work), physicians reported a slight preference for targeted treatments (M=2.3, SD=1.1, Mdn=2.0, IQR 2-3). On a 1-5 Likert-type agreement scale, physicians reported it is important to educate patients about how specific features of their MM may affect response rates (M=4.1, SD=0.7, Mdn=4.0, IQR 4-5) and time to progression (M=4.1, SD=0.8, Mdn=4.0, IQR 4-5). **Conclusions:** Conclusions: In our study of physicians primarily based in a community setting, most ordered conventional karyotyping or FISH testing for their patients and utilized these test results to guide treatment choices. MRD assessments were ordered in a third of cases and used to guide management in a third of cases when ordered. These findings highlight the importance of establishing clear pathways to guide decision-making in MM.

Josip Benčević" Slavonski Brod; [12]General Hospital Zadar; [13]General Hospital Šibenik; [14]General Hospital Pula; [15]General Hospital Čakovec; [16]General Hospital Varaždin; [17]General Hospital Dubrovnik

Introduction: Introduction of daratumumab in treatment of multiple myeloma (MM) lead to major improvements of patient's outcomes, both in the newly diagnosed and in the relapse/refractory (RR) settings. However, there are significant differences between outcomes reported in clinical trials and real-world evidence (RWE) data. The aim of this study was to analyze data for RR multiple myeloma patients treated with daratumumab and to compare it with those reported in literature (both RWE and clinical trials). **Methods:** We performed a retrospective analysis of outcomes of RRMM patients treated with daratumumab, in combination with bortezomib and dexamethasone (DVd) or lenalidomide and dexamethasone (DRd) in 12 Croatian hematology centers in the period between June 2019 and February 2023 (daratumumab available and reimbursed since June 2019). **Results:** A total of 329 patients with RR myeloma were included. Median age at the start of daratumumab treatment for the whole group was 68 years (range 42 – 93). There were 166 male and 163 female subjects. Median number of previous lines of therapies was 3 (range 2 – 8). 156 patients (47%) previously underwent autologous stem cell transplantation (ASCT) in the first line of treatment and 3 patients had allogeneic stem cell transplant. 302 patients (92%) were bortezomib exposed and 81 (25%) lenalidomide exposed. Only 11 (3%) and 21 (6%) of patients were exposed to carfilzomib and ixazomib, respectively. DVd was choice of therapy in 76 patients (23%) and DRd in 253 patients (77%). In the DVd group response rate (better or equal to partial response; PR) was 66%, while in the DRd group response rate was 76.8%. In the DVd group median follow up was 13 months and median progression free survival (PFS) was 18 months. In the DRd group median follow up was 15.2 months and median PFS was 24 months. Overall survival at 2 years was 63% in DRd group and 59% in DVd group. In the DRd group anemia, neutropenia and thrombocytopenia were reported in 51%, 40% and 56% patients, respectively. In the DVd group anemia, neutropenia and thrombocytopenia were reported in 50%, 42% and 16% patients, respectively. Infective complications were reported in 46% of patients in both groups. During follow up a total of 112 patients died (43 in the DVd and 83 in the DRd group. **Conclusions:** This RWE analysis validates efficacy of daratumumab in RR MM patients with acceptable and manageable toxicities. Similar outcomes were also reported in RR MM group of patients by other RWE analyses. There are significant discrepancies between RWE data and data reported in clinical trials; median PFS being much shorter in RWE analyses. These discrepancies are possibly due to different study populations.

Introduction: Multiple Myeloma (MM) is an incurable plasma cell neoplasm associated with high mortality and morbidity. Regardless of the remarkable advances in the last decade, more effective, well-tolerated therapies and personalized strategies are needed, especially in the setting of relapsed/refractory MM (RRMM). The CharisMMa-Portugal is the first study in Portugal aiming to describe RRMM patients'(pts) characteristics and management. **Methods:** This was an observational, cross-sectional, multicenter study on RRMM pts routinely treated at 7 public hospitals in Portugal. The study enrolled RRMM pts diagnosed in the previous 5 years presenting with RRMM in the 6 months prior to data collection. Data were collected from medical records during the clinical appointments (2020-2022). Sociodemographic, diagnosis-related information, clinical characterization of the last RR episode as well as treatment details since diagnosis were collected. Pts provided their written informed consent (ClincialTrials.gov ID - NCT04135963). **Results:** Out of the 74 pts screened, 62 were analyzed. Most pts (55%) were male, median age at diagnosis was 65 (IQR: 57-71) years. Nearly 68% were urban residents and the median home-to-hospital distance was 24.5 km (IQR:10-50). Most pts had completed at least the 9th school grade (65.5%) and were retired (62.3%). International Staging System (ISS) stages II and III (37.1% and 40.3%, respectively), and ECOG-PS 0 and ECOG-PS 1 (37.3% each) were the most common. Triplet regimens were used as the first treatment after diagnosis in 69.4% of the pts. The preferred route of administration was the combination of oral plus subcutaneous (78.9%), and 30.6% received a prior stem cell transplant. At the last RRMM episode, nearly 63% of pts had at least one comorbidity. Eleven of 24 (45.8%) pts presented cytogenetic abnormalities, of which 8 were high risk and three were not classified.. At the last RRMM episode, 75% of pts initiated second-line treatment, 23.2% third-line and 1.8% fourth-line. Triplets were the most common (67.1%), while oral plus subcutaneous (39.6%) and all-oral (32.1%) were the most frequent routes of administration. Overall, proteasome inhibitors (PIs) and immunomodulators (IMIDs) were prevalent in most treatment combinations (PIs = 26.8%, IMIDs = 37,5%, PI+IMIDs = 17,9%). At last relapse, median number of visits to the hospital were four, while 51.6% of pts required a CT scan and 32.3% an MRI. **Conclusions:** This study provides a comprehensive picture of the current real world landscape of RRMM in Portugal. The treatment patterns described reveal the complexity of treating the refractory stages of the disease with several previous treatment lines. The socio-demographic and clinical characterization of these pts as well as the healthcare resource utilization in this setting can inform stakeholders' decision making on optimizing health policies.

Cutaneous presentation of multiple myeloma in relapse after AutoPBSCT

Lejla Ibricevic Balic[1], Lejla Burazerovic[1]

[1]Clinical Center Sarajevo University

Introduction: Cutaneous manifestations of multiple myeloma are very rare with fewer than 100 cases described in the literature so far. Lesions appear in the form of nodules or plaques that can be erythematous, purple or skin-colored with a diameter of 0.5 to 3 cm. These lesions are sign of poor prognosis and refractory to standard therapy. We present the case of a 49-year-old male patient with multiple myeloma, who at the time of relapse presented with skin lesions, so far first reported case in BIH. **Methods:** The diagnosis of multiple myeloma, IgG kappa in clinical stage III – R/ISS was made in May 2020 at the Clinic of Hematology of the Clinical Center of the University of Sarajevo. Until October 2021, he was treated with chemotherapy, irradiation, and autologous transplantation followed by maintenance therapy with Revlimid. In decembar 2021. the patient was admitted with painful purple skin nodules localized in the right femoral region. Biochemical findings were consistent with anemia (Hb 96), thrombocytopenia (Plt 58),

Introduction: Multiple Myeloma (MM) is an incurable plasma cell neoplasm associated with high mortality and morbidity. Regardless of the remarkable advances in the last decade, more effective, well-tolerated therapies and personalized strategies are needed, especially in the setting of relapsed/refractory MM (RRMM). The CharisMMa-Portugal is the first study in Portugal aiming to describe RRMM patients'(pts) characteristics and management. **Methods:** This was an observational, cross-sectional, multicenter study on RRMM pts routinely treated at 7 public hospitals in Portugal. The study enrolled RRMM pts diagnosed in the previous 5 years presenting with RRMM in the 6 months prior to data collection. Data were collected from medical records during the clinical appointments (2020-2022). Sociodemographic, diagnosis-related information, clinical characterization of the last RR episode as well as treatment details since diagnosis were collected. Pts provided their written informed consent (ClincialTrials.gov ID - NCT04135963). **Results:** Out of the 74 pts screened, 62 were analyzed. Most pts (55%) were male, median age at diagnosis was 65 (IQR: 57-71) years. Nearly 68% were urban residents and the median home-to-hospital distance was 24.5 km (IQR:10-50). Most pts had completed at least the 9th school grade (65.5%) and were retired (62.3%). International Staging System (ISS) stages II and III (37.1% and 40.3%, respectively), and ECOG-PS 0 and ECOG-PS 1 (37.3% each) were the most common. Triplet regimens were used as the first treatment after diagnosis in 69.4% of the pts. The preferred route of administration was the combination of oral plus subcutaneous (78.9%), and 30.6% received a prior stem cell transplant. At the last RRMM episode, nearly 63% of pts had at least one comorbidity. Eleven of 24 (45.8%) pts presented cytogenetic abnormalities, of which 8 were high risk and three were not classified.. At the last RRMM episode, 75% of pts initiated second-line treatment, 23.2% third-line and 1.8% fourth-line. Triplets were the most common (67.1%), while oral plus subcutaneous (39.6%) and all-oral (32.1%) were the most frequent routes of administration. Overall, proteasome inhibitors (PIs) and immunomodulators (IMIDs) were prevalent in most treatment combinations (PIs = 26.8%, IMIDs = 37,5%, PI+IMIDs = 17,9%). At last relapse, median number of visits to the hospital were four, while 51.6% of pts required a CT scan and 32.3% an MRI. **Conclusions:** This study provides a comprehensive picture of the current real world landscape of RRMM in Portugal. The treatment patterns described reveal the complexity of treating the refractory stages of the disease with several previous treatment lines. The socio-demographic and clinical characterization of these pts as well as the healthcare resource utilization in this setting can inform stakeholders' decision making on optimizing health policies.

Cutaneous presentation of multiple myeloma in relapse after AutoPBSCT

Lejla Ibricevic Balic[1], Lejla Burazerovic[1]

[1]Clinical Center Sarajevo University

Introduction: Cutaneous manifestations of multiple myeloma are very rare with fewer than 100 cases described in the literature so far. Lesions appear in the form of nodules or plaques that can be erythematous, purple or skin-colored with a diameter of 0.5 to 3 cm. These lesions are sign of poor prognosis and refractory to standard therapy. We present the case of a 49-year-old male patient with multiple myeloma, who at the time of relapse presented with skin lesions, so far first reported case in BIH. **Methods:** The diagnosis of multiple myeloma, IgG kappa in clinical stage III – R/ISS was made in May 2020 at the Clinic of Hematology of the Clinical Center of the University of Sarajevo. Until October 2021, he was treated with chemotherapy, irradiation, and autologous transplantation followed by maintenance therapy with Revlimid. In decembar 2021. the patient was admitted with painful purple skin nodules localized in the right femoral region. Biochemical findings were consistent with anemia (Hb 96), thrombocytopenia (Plt 58),

renal imparement (urea 11.2, creatinine 208), increased IgG, kappa light chains and Bence-Jonce proteinuria. A punch biopsy of the nodule showed infitration of entire dermis with monoclonal plasma cells. The cells were: CD38+, CD138+, CD117 focal+, CD56 +, LCA-, MPO staining of individual cells, CK-, CD34 + in blood vessels. Numerous atypical mitoses are present. A bone marrow biopsy showed up to 5% moncolonal plasma cells. He received Revlimid/Melphalan/Dexa, one cycle. Skin lesions resolved partially. Unfortunately he deceased month later, due to the progressionth of myeloma. **Results:** Cutaneous lesions of myloma tend to occur with relapses and in highly aggressive and progressive forms of multiple myeloma. In both cases the prognosis is poor with an average life expectancy of 12 months post diagnosis median survival is about 8 months, with less than 20% of patients found to be progression free at 5 years. Histopathological findings are characterised by monomorphic dermal and subcutaneous infiltrates of plasma cells. Immunohistochemically we see monoclonality of the plasma cells which have strong immunoexpression for CD138 (6). These lesions can occur anywhere in the skin but are most commonly seen in the chest and abdomen (44%) involvement of the skin of the extremities is less common. **Conclusions:** Treatment for cutaneous plasmacytoma in multiple myeloma involves chemotherapy, steroids and local radiotherapy. Surgical excision has a role in lesions resistant to radiotherapy or where lesions are very large and symptomatic.

Bendamustine (B) is associated with low response rates in heavily pretreated relapsed refractory multiple myeloma (RRMM)

Zhubin Gahvari[1], Timothy Schmidt[1], Matthew Brunner[1], Jason Bergsbaken[1], Natalie Callander[1]

[1]University of Wisconsin

Introduction: Bendamustine (B), singly or in combination, is reported to have significant activity in relapsed multiple myeloma, with several publications noting overall response rates (ORR) of 49%-60%, and PFS of 11.3 months when given in combination with bortezomib and lenalidomide (1, 2). The advent of CAR-T has also called into question the use of B, due to potential harmful effects on lymphocytes, that could ultimately influence the ability to collect adequate T cells for use, or possibly response to bispecific engagers. **Methods:** We performed a retrospective analysis of all RRMM patients who received B or a B combination between 2015 to 2022. **Results:** A total of 44 pts were treated. Median age 67 (range 41-83), Female (12/44 or 27%). Median previous lines of therapy 6 (range 3-15); 98% of pts were triple refractory (only 1 pt had not received anti CD 38 antibody therapy), and the majority (90%) had previous autologous transplant, and most were penta-refractory. Twenty-seven % of patients had high risk cytogenetics at diagnosis. Median time from diagnosis to B combination was 26 mo. (range 3-192 mo.). The median time on treatment was 3 mo. (range 1-12 mo.). ORR was 25% (11/44, with 1 VGPR, 10 PR) with a median PFS of 6.5 mo. and median OS of 18 mo. (range 3-48 mo.) calculated from time of B combo until death. One pt died of sepsis, grade 3/4 hematologic toxicity occurred in 50% of pts. Inclusion of bortezomib, pomalidomide or lenalidomide in the regimen did not appear to increase response rate. After failing B, the most effective salvage appeared to be second auto transplant or bispecific engager. Six patients subsequently received BCMA directed therapy, with 2/4 failing CAR-T treatment within 30 days of transplant. **Conclusions:** Conclusion: B either as a single agent or combination was associated with a 25% overall response rate. In heavily pretreated RRMM patients, alternative therapies should probably be considered, and B should likely be avoided in patients who are undergoing CAR-T transplantation. **References:** 1. Introduction: Belamaf, a first-in-class B-cell maturation antigen-targeting antibody-drug conjugate approved in the EU for treatment of RRMM, has demonstrated deep and durable responses as monotherapy. This study explores real-world (RW) use, effectiveness, and safety of belamaf in Europe, including the monitoring and management of ocular events. **Methods:** This ongoing non-interventional, retrospective and prospective study includes adult patients (pts) with RRMM receiving belamaf in routine clinical care, consistent with approved labelling. The primary objective is to characterize RW pt demographics and disease characteristics. The key secondary objective is to identify pts who experience belamaf-related ocular adverse events (AEs) of special interest (AESI). Secondary outcomes include incidence of ocular AESIs,

renal imparement (urea 11.2, creatinine 208), increased IgG, kappa light chains and Bence-Jonce proteinuria. A punch biopsy of the nodule showed infitration of entire dermis with monoclonal plasma cells. The cells were: CD38+, CD138+, CD117 focal+, CD56 +, LCA-, MPO staining of individual cells, CK-, CD34 + in blood vessels. Numerous atypical mitoses are present. Introduction: Belamaf, a first-in-class B-cell maturation antigen-targeting antibody-drug conjugate approved in the EU for treatment of RRMM, has demonstrated deep and durable responses as monotherapy. This study explores real-world (RW) use, effectiveness, and safety of belamaf in Europe, including the monitoring and management of ocular events. **Methods:** This ongoing non-interventional, retrospective and prospective study includes adult patients (pts) with RRMM receiving belamaf in routine clinical care, consistent with approved labelling. The primary objective is to characterize RW pt demographics and disease characteristics. The key secondary objective is to identify pts who experience belamaf-related ocular adverse events (AEs) of special interest (AESI). Secondary outcomes include incidence of ocular AESIs,

dose modifications, treatment discontinuation, and treatment response. **Results:** This first interim analysis (as of March 17, 2023) included 37 pts from Italy, Austria, Norway, Germany, Belgium, Spain, and Greece (34 received ≥1 belamaf dose). Mean age was 70.4 years (≥75 years, n=15; 44%); 68% were female. Median time since diagnosis was 86.4 months. Prior therapy data were available for 31 pts (91%): 25 (74%) had ≥4 prior lines of therapy; all 31 had prior exposure to proteasome inhibitors, anti-CD38 therapies (daratumumab 85%), and immunomodulatory therapies; and 91% were triple-class refractory. At baseline, 24 pts (71%) had ≥1 prior/ongoing comorbidity including cardiac disease (n=11; 32%), diabetes (n=10; 29%), eye disease (n=10; 29%), pulmonary disease (n=9; 27%), vascular disorders (n=9; 27%), endocrine disorders (n=7; 21%), and renal disease (n=7; 21%). Most pts (n=29, 85%) saw an ophthalmologist before initiating belamaf; 80%, 78%, and 90% visited an ophthalmologist prior to their 2nd, 3rd and 4th doses. Median treatment time was 4.8 months, and 16 pts (47%) had ≥4 months of follow-up. Overall, 22 pts (65%) reported ocular AESIs including keratopathy (n=16; 47% [Grade ≥2, n=12]), best corrected visual acuity change (n=5; 15%), corneal erosion (n=2; 6%), and dry eye (n=1; 3%). AESIs led to dose reduction in 2 pts (6%) and dose delays in 10 pts (29%). Discontinuation was due to disease progression (n=7; 21%) or AESI (n=3; 9%); 9 pts experienced disease progression or died. Median RW progression-free survival was 3.9 months. Efficacy data are subject to additional follow-up and will be presented. **Conclusions:** This study demonstrates that in Europe belamaf is used routinely in later lines of therapy, in line with the current approved indication in the EU, including in pts who are aged ≥75 years, have current or prior comorbidities, and/or are triple class refractory. Our data suggest that ocular AEs are being monitored appropriately with ophthalmologist visits and managed using dose modifications. Treatment discontinuations occurred primarily due to progressive disease. Updated RW clinical efficacy data will be forthcoming.

P-239

Dynamic risk model: a novel approach incorporating functional high risk factors for predicting survival outcomes in patients with relapsed/refractory multiple myeloma

Hee Jeong Cho[1], Myung-Won Lee[2], Ju-Hyung Kim[1], Dong Won Baek[1], Sang-Kyun Sohn[1], Jong Gwang Kim[1], Joon Ho Moon[1]

[1]Department of Hematology-Oncology, Kyungpook National University Hospital, School of Medicine, Kyungpook National University, Daegu, South Korea; [2]Chungnam National University Hospital

Introduction: Early relapse and refractoriness to novel agents have been recognized as high-risk features associated with resistance to subsequent therapy and reduced overall survival in patients with multiple myeloma (MM). Newly identified risk factors following such treatments are referred to as functional high risk or dynamic high risk. In this study, we propose a novel risk model aimed at predicting survival outcomes in patients with relapsed/refractory MM (RRMM), incorporating functional high risk factors. **Methods:** We conducted a retrospective review of medical records for RRMM patients who underwent a second line of therapy at Kyungpook National University Hospital and Chungnam National University Hospital between 2011 and 2021. Early relapse was defined as biochemical or overt relapse occurring within 18 months after the initiation of frontline therapy. We assigned weighted scores based on the range of hazard ratio (HR) derived from the Cox hazard model for each risk factor. Subsequently, we classified risk groups by summing the scores for each risk factor. **Results:** A total of 141 patients with RRMM were included in the analysis. The median age at diagnosis was 65.7 years (range: 33-80). Early relapse was observed in 77 patients (54.6%). Following relapse, all of the patients received carfilzomib (72.3%)- or ixazomib (27.7%)-based treatment. Early relapse was identified as a significant risk factor for survival prediction (HR 2.56, p= 0.002). Other variables at relapse, including hemoglobin (Hb), platelet count, LDH, albumin, beta 2 microglobulins (B2GM), and plasmacytoma, were determined to be relevant risk factors affecting survival outcomes. The scores assigned were 2 for early relapse, LDH, and plasmacytoma, 0.5 for Hb, and 1 for albumin. Platelet count and B2GM were excluded from the weighting score calculation due to their relatively insignificant HR values. The risk model for survival prediction, referred to as the Dynamic Risk Model, classified RRMM patients into three stages: stage I (total score 0-2), stage II (2.5-4), and stage III (4.5-7.5). Seventy patients were included in the survival outcome analysis using the Dynamic Risk Model, after excluding 71 patients due to missing laboratory or imaging data. Of the analyzed patients, 29 (41.4%) were classified as stage I, 25 (35.7%) as stage II, and 16 (22.9%) as stage III. The new model effectively differentiated survival outcomes among the stages in RRMM patients, with 24-month OS rates of 95.7%, 42.3%, and 16.2% in stages I, II, and III, respectively ($p < 0.001$). The 24-month progression-free survival rates were 57.3%, 35.7%, and 0.0% in stages I, II, and III, respectively ($p < 0.001$). **Conclusions:** The integration of early relapse and readily accessible variables within the Dynamic Risk Model demonstrated a remarkable ability to prognosticate survival outcomes in patients with RRMM. Significantly, this model represents the first application of functional high risk in reevaluating risk stratification within the RR setting.

dose modifications, treatment discontinuation, and treatment response. **Results:** This first interim analysis (as of March 17, 2023) included 37 pts from Italy, Austria, Norway, Germany, Belgium, Spain, and Greece (34 received ≥1 belamaf dose). Mean age was 70.4 years (≥75 years, n=15; 44%); 68% were female. Median time since diagnosis was 86.4 months. Prior therapy data were available for 31 pts (91%): 25 (74%) had ≥4 prior lines of therapy; all 31 had prior exposure to proteasome inhibitors, anti-CD38 therapies (daratumumab 85%), and immunomodulatory therapies; and 91% were triple-class refractory. At baseline, 24 pts (71%) had ≥1 prior/ongoing comorbidity including cardiac disease (n=11; 32%), diabetes (n=10; 29%), eye disease (n=10; 29%), pulmonary disease (n=9; 27%), vascular disorders (n=9; 27%), endocrine disorders (n=7; 21%), and renal disease (n=7; 21%). Most pts (n=29, 85%) saw an ophthalmologist before initiating belamaf; 80%, 78%, and 90% visited an ophthalmologist prior to their 2nd, 3rd and 4th doses. Median treatment time was 4.8 months, and 16 pts (47%) had ≥4 months of follow-up. Overall, 22 pts (65%) reported ocular AESIs including keratopathy (n=16; 47% [Grade ≥2, n=12]), best corrected visual acuity change (n=5; 15%), corneal erosion (n=2; 6%), and dry eye (n=1; 3%). AESIs led to dose reduction in 2 pts (6%) and dose delays in 10 pts (29%). Discontinuation was due to disease progression (n=7; 21%) or AESI (n=3; 9%); 9 pts experienced disease progression or died. Median RW progression-free survival was 3.9 months. Efficacy data are subject to additional follow-up and will be presented. **Conclusions:** This study demonstrates that in Europe belamaf is used routinely in later lines of therapy, in line with the current approved indication in the EU, including in pts who are aged ≥75 years, have current or prior comorbidities, and/or are triple class refractory. Our data suggest that ocular AEs are being monitored appropriately with ophthalmologist visits and managed using dose modifications. Treatment discontinuations occurred primarily due to progressive disease. Updated RW clinical efficacy data will be forthcoming.

Introduction: Early relapse and refractoriness to novel agents have been recognized as high-risk features associated with resistance to subsequent therapy and reduced overall survival in patients with multiple myeloma (MM). Newly identified risk factors following such treatments are referred to as functional high risk or dynamic high risk. In this study, we propose a novel risk model aimed at predicting survival outcomes in patients with relapsed/refractory MM (RRMM), incorporating functional high risk factors. **Methods:** We conducted a retrospective review of medical records for RRMM patients who underwent a second line of therapy at Kyungpook National University Hospital and Chungnam National University Hospital between 2011 and 2021. Early relapse was defined as biochemical or overt relapse occurring within 18 months after the initiation of frontline therapy. We assigned weighted scores based on the range of hazard ratio (HR) derived from the Cox hazard model for each risk factor. Subsequently, we classified risk groups by summing the scores for each risk factor. **Results:** A total of 141 patients with RRMM were included in the analysis. The median age at diagnosis was 65.7 years (range: 33-80). Early relapse was observed in 77 patients (54.6%). Following relapse, all of the patients received carfilzomib (72.3%)- or ixazomib (27.7%)-based treatment. Early relapse was identified as a significant risk factor for survival prediction (HR 2.56, p= 0.002). Other variables at relapse, including hemoglobin (Hb), platelet count, LDH, albumin, beta 2 microglobulins (B2GM), and plasmacytoma, were determined to be relevant risk factors affecting survival outcomes. The scores assigned were 2 for early relapse, LDH, and plasmacytoma, 0.5 for Hb, and 1 for albumin. Platelet count and B2GM were excluded from the weighting score calculation due to their relatively insignificant HR values. The risk model for survival prediction, referred to as the Dynamic Risk Model, classified RRMM patients into three stages: stage I (total score 0-2), stage II (2.5-4), and stage III (4.5-7.5). Seventy patients were included in the survival outcome analysis using the Dynamic Risk Model, after excluding 71 patients due to missing laboratory or imaging data. Of the analyzed patients, 29 (41.4%) were classified as stage I, 25 (35.7%) as stage II, and 16 (22.9%) as stage III. The new model effectively differentiated survival outcomes among the stages in RRMM patients, with 24-month OS rates of 95.7%, 42.3%, and 16.2% in stages I, II, and III, respectively ($p < 0.001$). The 24-month progression-free survival rates were 57.3%, 35.7%, and 0.0% in stages I, II, and III, respectively ($p < 0.001$). **Conclusions:** The integration of early relapse and readily accessible variables within the Dynamic Risk Model demonstrated a remarkable ability to prognosticate survival outcomes in patients with RRMM. Significantly, this model represents the first application of functional high risk in reevaluating risk stratification within the RR setting.

Introduction: B-cell maturation antigen (BCMA)-targeting therapies are promising treatments (tx) for patients (pts) with multiple myeloma (MM), and data are required to understand tx sequencing to optimize pt outcomes. CARTITUDE-2 (NCT04133636) is a phase 2, multicohort study evaluating the efficacy and safety of ciltacabtagene autoleucel (cilta-cel), an approved anti-BCMA chimeric antigen receptor (CAR)-T cell therapy, in several MM pt populations. CARTITUDE-2 Cohort C enrolled pts with heavily pretreated relapsed/refractory MM who were previously exposed to a noncellular anti-BCMA tx. We present efficacy and safety results for cohort C pts with a median follow-up of 18.0 months (mo). **Methods:** Cohort C pts had progressive MM after tx with a proteasome inhibitor, immunomodulatory drug, anti-CD38 antibody, and a noncellular BCMA-targeting agent. A single cilta-cel infusion (target dose: 0.75×10^6 CAR+ viable T cells/kg [range: $0.5–1.0\times10^6$ CAR+ viable T cells/kg]) was administered 5–7 days post lymphodepletion. The primary endpoint was minimal residual disease (MRD) negativity at 10^{-5} threshold. Secondary endpoints included response rates (per International Myeloma Working Group criteria) and safety. **Results:** As of June 1, 2022, 20 pts (13 ADC, 7 BsAb exposed; 1 pt in the ADC group had prior BsAb tx) received cilta-cel. 6 pts (30%) had anti-BCMA tx as their last line of therapy (LOT; n=4 ADC, n=2 BsAb). At baseline, median age was 62.5 years (range, 44–81); 60% were male; 15% had high-risk cytogenetics (all del17p); 25% had extramedullary disease; received a median of 8 (range, 4–13) prior LOT. Median cilta-cel dose administered was 0.61×10^6 (range, 0.21×10^6–0.83×10^6) CAR+ viable T cells/kg; 1 pt received a below-target dose range. At a median follow-up of 18.0 mo (range, 0.6–22.7), 7 of 10 evaluable pts (70%) in the full cohort were MRD negative at 10^{-5} threshold (5 of 7 [71.4%] in the ADC group, and 2 of 3 [66.7%] in the BsAb group). The overall response rate was 60%; ADC, 61.5%; BsAb, 57.1%. Median duration of response was 12.3 mo (95% CI, 7.2–NE); ADC, 13.3 mo (7.2–NE); BsAb, 8.2 mo (4.4–NE). Median progression-free survival was 9.1 mo (95% CI, 1.5–13.8); ADC, 9.5 mo (1.0–15.2); BsAb, 5.3 mo (0.6–NE). The most common adverse events (AEs) were hematologic.12 pts had cytokine release syndrome (6 in ADC, 6 in BsAb, [all grade 1/2]); resolved in all. 4 pts had immune effector cell-associated neurotoxicity syndrome (2 in ADC [grade 3/4]; 2 in BsAb [1 grade 3/4]); resolved in 3. No pt had movement or neurocognitive tx-emergent AE/parkinsonism. Total of 12 deaths occurred (7 in ADC; 5 in BsAb [1 due to tx-related C. difficile colitis]). **Conclusions:** These results in the context of published data, including CARTITUDE-1, suggest that cilta-cel in anti-BCMA naive pts offers better outcomes, although this interpretation needs to be cautioned by the small number of pts. Updated results and additional correlative analyses will be presented.

African American relapsed/refractory multiple myeloma patients have a progression free survival benefit with selinexor treatment in the STORM study

Craig Cole[1], Anne Opalikhin[2], Matthew McCartney[3], Caroline Heideman[4], Swetha Pentapati[4], Ling Wang[5]

[1]Michigan State University-Karmanos Cancer Institute; [2]Michigan State University College of Human Medicine, Grand Rapids, Michigan; [3]McLaren Greater Lansing, Michigan State University-College of Osteopathic Medicine; [4]Michigan State University-Karmanos Cancer Institute, McLaren Greater Lansing; [5]Division of Occupational and Environmental medicine, Department of Medicine, College of Human Medicine, Michigan State University

Introduction: Multiple Myeloma (MM) is the 2nd most common hematologic malignancy in the US, though survival in patients with MM has increased over the past decade. Survival improvements in African Americans (AAs) have been smaller, which may be due to disparity in access to therapies. There are also key differences in MM biology between races. Given underrepresentation of minorities in clinical trials, we analyzed whether outcomes were similar between AAs and other races in the phase 2 STORM trial (NCT02336815) of selinexor. Selinexor, an oral, first-in-class selective inhibitor of nuclear export via exportin 1, has proven efficacy for refractory MM. This is the first race subgroup analysis of selinexor in MM clinical trials. **Methods:** Pts from STORM who received study drug (N=202) were included. Pts with heavily pretreated MM, including triple-class and penta- refractory MM refractory to the last line of therapy were given selinexor (80mg) + dexamethasone (20mg) twice weekly. We conducted a retrospective racial subgroup analysis. Cox proportional modeling was used to determine the hazard ratio (HR) for MM relapse between races controlling for covariates. **Results:** AAs represented 17% of pts (35 AAs, 148 White, 2 Asian, 11 other and 6 missing). AAs were younger compared to other races (median age 60.7 vs 65.3) with more females (74.3% vs 40.7%). Cytogenetic abnormalities and R-ISS staging were similar between races. AAs had a median progression free survival (PFS) of 6.5 mos (95% CI 4.7, NR) compared with 3.7 mos (95% CI 2.8, 4.6; p = 0.035) for other races. Overall response rate (ORR) was 25.7% (95% CI 12.5, 43.3) in AA pts vs 23.4% [17.2, 30.5] in other races), clinical benefit rate (37.1% [21.5, 55.1] vs 35.9% [28.7, 43.7]), median duration of response (5.6 mos [2.1, NR] vs 5.3 [3.6, NR]), median duration of treatment (9 wks [IQR 3-22 wks] vs 8 wks [4-16 wks]), and mean dose intensity (117.9 mg/wks [STD 35.1] vs 117.1 [34.7]) were similar between groups. Rates of Adverse Events (AEs) ≥ grade 3 (94.3% vs 95.8%), and AE-related dose reductions (45.7% vs 54.5%), discontinuations (22.9% vs 30.5%), and deaths (5.7% vs 10.8%) were also similar. The adjusted HR for MM relapse in AAs was 0.45 (95% CI 0.22, 0.92; p=0.028) after controlling for

Overall response rate (ORR) was 25.7% (95% CI 12.5, 43.3) in AA pts vs 23.4% [17.2, 30.5] in other races), clinical benefit rate (37.1% [21.5, 55.1] vs 35.9% [28.7, 43.7]), median duration of response (5.6 mos [2.1, NR] vs 5.3 [3.6, NR]), median duration of treatment (9 wks [IQR 3-22 wks] vs 8 wks [4-16 wks]), and mean dose intensity (117.9 mg/wks [STD 35.1] vs 117.1 [34.7]) were similar between groups. Rates of Adverse Events (AEs) ≥ grade 3 (94.3% vs 95.8%), and AE-related dose reductions (45.7% vs 54.5%), discontinuations (22.9% vs 30.5%), and deaths (5.7% vs 10.8%) were also similar. The adjusted HR for MM relapse in AAs was 0.45 (95% CI 0.22, 0.92; p=0.028) after controlling for

gender, age and prior therapy. **Conclusions:** This subgroup analysis showed that compared with other races, AAs pts were younger and included a greater percentage of women. Although ORRs were similar, AAs had a longer PFS compared with other races after adjusting for covariates. Despite small sample size, the differences were statistically significant. Dose adjustments and tolerability were relatively comparable. It is unclear if the better PFS reflects a different biology, pharmacology of selinexor or both. These results could assist in the placement of selinexor in the treatment sequence of relapsed refractory MM for AAs.

Real-world treatment patterns and clinical outcomes amongst patients with relapsed/refractory multiple myeloma previously treated with lenalidomide and an anti-CD38 monoclonal antibody

Andrew Cowan[1], Jessica Katz[2], Carrie Ho[3], Tao Gu[2], Thomas Marshall[2], Fangyi Gu[2], Yuexin Tang[2]

[1]University of Washington, Seattle, WA, USA; [2]Bristol Myers Squibb, Princeton, NJ, USA; [3]University of Washington/Fred Hutch Cancer Center, Seattle, WA, USA

Introduction: NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) recommend the use of novel-immune based therapies in late relapse (≥3 prior therapies) and triple-class exposed (TCE)/penta-refractory patients (pts) with multiple myeloma (MM). Limited guidance is provided in pts with early relapsed (1–3 prior therapies) MM regarding anti-CD38 monoclonal antibody (mAb) exposure, with increasing use of lenalidomide (LEN) and an anti-CD38 mAb in 1L/2L (first-/second-line) treatment (Tx). Real-world evidence is needed to better understand Tx patterns and clinical outcomes post-LEN and an anti-CD38 mAb. **Methods:** This retrospective cohort study used Flatiron Health electronic medical records from January 1st, 2011 to June 30th, 2022. Pts with MM were included if they were previously treated with LEN and an anti-CD38 mAb in the same or different lines, and had initiated the next line of Tx (index regimen). Descriptive analyses were conducted to assess baseline demographics, clinical factors, Tx history, and index Tx patterns. Progression-free survival (PFS) and overall survival (OS) were estimated using Kaplan–Meier plots. Subgroup analyses of the survival outcomes were conducted by selected risk groups: high-risk cytogenetics (≥1 cytogenetic factors: del 17p, t(4;14), t(14;16), t(14;20), and amplification 1q21), elderly (≥75 years old), ECOG score ≥2, and refractory to anti-CD38 mAbs. Multivariate cox proportional hazard regressions were used to assess the association between baseline pt characteristics and survival outcomes. **Results:** Of 845 pts, 96.4% started the index regimen during 2017–2022. The median age at start of index regimen (index date) was 69; 64.4% were White and 15.0% were African American. Most pts (85.7%) were treated in the community setting; 35.5% had high-risk cytogenetics; 18.3% had ECOG score ≥2. Median time from initial MM diagnosis to index date was 36.5 months. Only 6.9% initiated the index regimen at 2L Tx, while 32.1% and 61.1% initiated at 3L and 4L+ Tx, respectively. Most pts (93.4%) were TCE and 44.8% were refractory to an anti-CD38 mAb. Daratumumab (DARA)/pomalidomide (POM)/dexamethasone (DEX) (10.7%), carfilzomib (CAR)/POM/DEX (5.2%), and CAR/DEX (4.7%) were the most frequently used index regimens. The median PFS and OS were 5.3 and 23.1 months, respectively. Those with high-risk cytogenetics, ECOG score ≥2, and refractory to anti-CD38 had shorter survival than their counterparts. **Conclusions:** In pts previously treated with LEN and an anti-CD38 mAb, DARA, CAR, and POM-based regimens were most used; however, there is no clear standard of care. Poor survival outcomes in the overall population and certain subgroups highlight the need for novel, effective, and safe agents to address unmet medical needs of this rapidly growing pt population with prior exposure to LEN and an anti-CD38 mAb. Improved outcomes in allo-HCT for multiple myeloma patients with thiotepa-busulfan-fludarabine conditioning regimen and post-transplant cyclophosphamide, sirolimus and mycophenolate mofetil

Javier de la Rubia[1], Juan Montoro[1], Jaime Sanz[1], Aitana Balaguer[1], Manuel Guerreiro[1], Ana Facal[1], Marta Villalba[1], Pedro Chorao[1], Mario Arnao[1], Alberto Louro[1], Miguel Sanz[1]

[1]Hospital La Fe

Introduction: The use of allogeneic hematopoietic stem cell transplantation (allo-HCT) in the treatment of multiple myeloma (MM) is a matter of ongoing controversy due to the transplant-related mortality (NRM) and relapse rate. Despite these limitations, efforts to improve supportive care measures, less toxic conditioning regimens, and more effective strategies to prevent graft-versus-host disease (GVHD) are being made to enhance the success of allo-HCT in MM. **Methods:** This study includes 25 patients with MM from a single institution who underwent allo-HCT with thiotepa-fludarabine-busulfan (TBF) conditioning regimen between January 2017 and December 2020. GVHD prophylaxis consisted of post-transplant cyclophosphamide (PTCy), sirolimus, and mycophenolate mofetil (MMF). Disease status at allo-HCT was defined based on the IMWG criteria. The probabilities of engraftment, acute and chronic GVHD, NRM, and relapse were estimated using the cumulative incidence method. Competing risk data were considered for different events. Kaplan-Meier estimate was used for unadjusted time-to-event analyses. GRFS analysis considered grade III-IV aGVHD, chronic extensive GVHD, relapse, graft failure, and death as events. **Results:** The median age at allo-HCT was 54 years. According to R-ISS at diagnosis, 5 (20%) pts were stage I, 11 (44%) stage II, 4 (16%) stage III, and was not available in 5 (20%). Nine (36%) pts had high-risk cytogenetic abnormalities. All patients received induction therapy with novel agents, and 24 (96%) received a triple-based one. The median number of prior lines of treatment before allo-HCT was 2 (range, 1-5). Twenty-three (92%) patients had received prior auto-HCT and 8 (32%) were refractory before allo-HCT. Disease status

gender, age and prior therapy. **Conclusions:** This subgroup analysis showed that compared with other races, AAs pts were younger and included a greater percentage of women. Although ORRs were similar, AAs had a longer PFS compared with other races after adjusting for covariates. Despite small sample size, the differences were statistically significant. Dose adjustments and tolerability were relatively comparable. It is unclear if the better PFS reflects a different biology, pharmacology of selinexor or both. These results could assist in the placement of selinexor in the treatment sequence of relapsed refractory MM for AAs.

Introduction: The use of allogeneic hematopoietic stem cell transplantation (allo-HCT) in the treatment of multiple myeloma (MM) is a matter of ongoing controversy due to the transplant-related mortality (NRM) and relapse rate. Despite these limitations, efforts to improve supportive care measures, less toxic conditioning regimens, and more effective strategies to prevent graft-versus-host disease (GVHD) are being made to enhance the success of allo-HCT in MM. **Methods:** This study includes 25 patients with MM from a single institution who underwent allo-HCT with thiotepa-fludarabine-busulfan (TBF) conditioning regimen between January 2017 and December 2020. GVHD prophylaxis consisted of post-transplant cyclophosphamide (PTCy), sirolimus, and mycophenolate mofetil (MMF). Disease status at allo-HCT was defined based on the IMWG criteria. The probabilities of engraftment, acute and chronic GVHD, NRM, and relapse were estimated using the cumulative incidence method. Competing risk data were considered for different events. Kaplan-Meier estimate was used for unadjusted time-to-event analyses. GRFS analysis considered grade III-IV aGVHD, chronic extensive GVHD, relapse, graft failure, and death as events. **Results:** The median age at allo-HCT was 54 years. According to R-ISS at diagnosis, 5 (20%) pts were stage I, 11 (44%) stage II, 4 (16%) stage III, and was not available in 5 (20%). Nine (36%) pts had high-risk cytogenetic abnormalities. All patients received induction therapy with novel agents, and 24 (96%) received a triple-based one. The median number of prior lines of treatment before allo-HCT was 2 (range, 1-5). Twenty-three (92%) patients had received prior auto-HCT and 8 (32%) were refractory before allo-HCT. Disease status

at allo-HCT was complete response/very good partial response (n=18, 72%), partial response (PR) (n=6, 24%), and less than PR (n=1, 4%). Donor type distribution was as follows: MSD (n=12, 48%), MUD (n=7, 28%), and Haplo (n=6, 24%). Peripheral blood was the stem cell source in 23 (92%) patients. All patients engrafted. Cumulative incidence of acute GVHD grade II-IV and III-IV were 20% (95%CI, 38-70%) and 8% (1-23%), respectively. The 3-year cumulative incidence of NRM was 22% (95%CI: 3-52%) and of chronic GVHD 27% (95%CI: 11-47%). The 3-year OS, EFS, and GRFS were 74% (58-95%), 69% (52-91%), and 54% (37-79%), respectively. **Conclusions:** In this real-life cohort study, allo-HCT with the TBF conditioning regimen and GCHD prophylaxis with PTCy, sirolimus, and MMF showed encouraging results. It led to reduced acute and chronic GVHD incidence, improved GRFS, and favorable survival rates. These findings suggest that this combination holds promise as an effective treatment option for MM patients considered candidates for an allo-HCT.

Teclistamab versus Belgian real-world clinical practice in triple-class exposed relapsed and refractory multiple myeloma patients using adjusted comparison

Michel Delforge[1], Sébastien Anguille[2], Julien Depaus[3], Nathalie Meuleman[4], Ann Van De Velde[2], Isabelle Vande Broek[5], Joris Diels[6], Nichola Erler-Yates[7], Sébastien Van Causenbroeck[8], Kirsten Van Nimwegen[9], Sophie Vandervennet[8], Susanne Lub[10], Marie-Christiane Madeleine Vekemans[11]

[1]University of Leuven, Leuven, Belgium; [2]Antwerp University Hospital; [3]CHU UCL Namur; [4]Institut Jules Bordet; [5]AZ Nikolaas; [6]Janssen Pharmaceutica NV, Beerse, Belgium; [7]Janssen-Cilag GmbH; [8]Janssen-Cilag NV; [9]Janssen-Cilag B.V; [10]Janssen-Cilag; [11]Department of Internal Medicine, Université Catholique de Louvain (UCLouvain), Brussels, Belgium

Introduction: Triple-class exposed (TCE) relapsed and refractory multiple myeloma (RRMM) patients have a poor prognosis and limited treatment options. Teclistamab, a BCMA x CD3 bispecific antibody, is being studied in TCE RRMM patients in the single-arm phase 1/2 MajesTEC-1 trial. We assessed the relative effectiveness of teclistamab vs Belgian real-world clinical practice (RWCP) using individual patient data (IPD) from MajesTEC-1 and BELCOMM (Belgium Comparator study in Multiple Myeloma). **Methods:** An external control arm for MajesTEC-1 was created from TCE RRMM patients treated with RWCP therapies from the BELCOMM cohort, a retrospective Belgian patient cohort. Patients with an ECOG score 0 or 1, who received ≥ 3 prior lines of therapy (LOTs), and at least 1 subsequent active MM therapy after becoming TCE, were selected. IPD were available for MajesTEC-1 patients (cut-off March 2022) and RWCP patients in the BELCOMM cohort (cut-off May 2021). Patients with multiple LOTs initiated after fulfilling the inclusion criteria contributed multiple times to the analyses. Inverse probability weighting (IPW) was used to adjust for imbalances in baseline covariates, estimating the average treatment effect in the treated population. Comparative effectiveness of teclistamab vs RWCP was estimated for overall response rate (ORR), very good partial response or better (≥VGPR) rate, progression-free survival (PFS), time to next treatment (TTNT) and overall survival (OS). For the binary endpoints (ORR and ≥VGPR), weighted logistic regression was used to estimate the relative effect of teclistamab vs RWCP with odds ratios (OR) transformed into response-rate ratios (RR) and 95% confidence intervals (CI). For time-to event endpoints (PFS, TTNT and OS) weighted Cox proportional hazards regression was used to estimate hazard ratios (HR) and 95% CIs. **Results:** 165 patients (165 LOTs) from the MajesTEC-1 cohort and 112 patients (237 LOTs) from the BELCOMM cohort were included in the intention-to-treat (ITT) analyses. All adjusted comparative analyses demonstrated statistically significant results in favor of teclistamab across all endpoints. The RR for teclistamab vs RPWC for ORR and ≥VGPR were 2.31 [95% CI: 1.69, 3.15] and 5.97 [3.80, 9.37], respectively. Teclistamab patients were 2.3 and 6.0 times more likely to reach ORR and ≥VGPR, respectively. The HR for teclistamab vs RWPC were 0.39 [0.29, 0.52] for PFS, 0.35 [0.27, 0.47] for TTNT, and 0.55 [0.40, 0.76] for OS. Sensitivity analyses using multivariable logistic regression and Cox regression analysis were consistent with the main analyses. **Conclusions:** Teclistamab was associated with significantly superior effectiveness compared with treatments administered in RWCP in Belgian TCE RRMM patients for each measure of clinical effectiveness. Results were consistent across sensitivity analyses and confirm previous indirect comparisons vs other RWPC cohorts. These findings highlight teclistamab's clinical benefit as a novel and effective treatment in TCE RRMM patients.

Introduction: The B-cell maturation antigen (BCMA)-targeting antibody-drug conjugate (ADC) belantamab mafodotin (belamaf) contains the cytotoxic molecule cysteine-monomethyl auristatin-F (cys-mcMMAF). Belamaf has been extensively tested in clinical trials at 2.5 mg/kg every 3 weeks (Q3W) in patients (pts) with relapsed/refractory multiple myeloma (RRMM) and a glomerular filtration

at allo-HCT was complete response/very good partial response (n=18, 72%), partial response (PR) (n=6, 24%), and less than PR (n=1, 4%). Donor type distribution was as follows: MSD (n=12, 48%), MUD (n=7, 28%), and Haplo (n=6, 24%). Peripheral blood was the stem cell source in 23 (92%) patients. All patients engrafted. Cumulative incidence of acute GVHD grade II-IV and III-IV were 20% (95%CI, 38-70%) and 8% (1-23%), respectively. The 3-year cumulative incidence of NRM was 22% (95%CI: 3-52%) and of chronic GVHD 27% (95%CI: 11-47%). The 3-year OS, EFS, and GRFS were 74% (58-95%), 69% (52-91%), and 54% (37-79%), respectively. **Conclusions:** In this real-life cohort study, allo-HCT with the TBF conditioning regimen and GCHD prophylaxis with PTCy, sirolimus, and MMF showed encouraging results. It led to reduced acute and chronic GVHD incidence, improved GRFS, and favorable survival rates. These findings suggest that this combination holds promise as an effective treatment option for MM patients considered candidates for an allo-HCT.

Inverse probability weighting (IPW) was used to adjust for imbalances in baseline covariates, estimating the average treatment effect in the treated population. Comparative effectiveness of teclistamab vs RWCP was estimated for overall response rate (ORR), very good partial response or better (≥VGPR) rate, progression-free survival (PFS), time to next treatment (TTNT) and overall survival (OS). For the binary endpoints (ORR and ≥VGPR), weighted logistic regression was used to estimate the relative effect of teclistamab vs RWCP with odds ratios (OR) transformed into response-rate ratios (RR) and 95% confidence intervals (CI). For time-to event endpoints (PFS, TTNT and OS) weighted Cox proportional hazards regression was used to estimate hazard ratios (HR) and 95% CIs. **Results:** 165 patients (165 LOTs) from the MajesTEC-1 cohort and 112 patients (237 LOTs) from the BELCOMM cohort were included in the intention-to-treat (ITT) analyses. All adjusted comparative analyses demonstrated statistically significant results in favor of teclistamab across all endpoints. The RR for teclistamab vs RPWC for ORR and ≥VGPR were 2.31 [95% CI: 1.69, 3.15] and 5.97 [3.80, 9.37], respectively. Teclistamab patients were 2.3 and 6.0 times more likely to reach ORR and ≥VGPR, respectively. The HR for teclistamab vs RWPC were 0.39 [0.29, 0.52] for PFS, 0.35 [0.27, 0.47] for TTNT, and 0.55 [0.40, 0.76] for OS. Sensitivity analyses using multivariable logistic regression and Cox regression analysis were consistent with the main analyses. **Conclusions:** Teclistamab was associated with significantly superior effectiveness compared with treatments administered in RWCP in Belgian TCE RRMM patients for each measure of clinical effectiveness. Results were consistent across sensitivity analyses and confirm previous indirect comparisons vs other RWPC cohorts. These findings highlight teclistamab's clinical benefit as a novel and effective treatment in TCE RRMM patients.

Belantamab mafodotin in patients with severely impaired renal function: a phase I, 2-part study to evaluate pharmacokinetics, safety and efficacy in patients with relapsed/refractory multiple myeloma

Seema Shafi-Harji[1], Courtney Nugent[2], Geraldine Ferron-Brady[2], Sosana Delimpasi[3], Meletios Dimopoulos[4], Yunxin Chen[5], Wee Joo Chng[6], Jae Hoon Lee[7], Sikander Ailawadhi[8], Krisstina Gowin[9], Michael Arning[10], Herbert Struemper[11]

[1]GSK, Stevenage, UK; [2]GSK, Collegeville, PA, USA; [3]General Hospital Evangelismos, Athens, Greece; [4]National and Kapodistrian University of Athens; [5]Singapore General Hospital, Singapore; [6]National University of Singapore, Singapore; [7]Gachon University, Seongnam-si, South Korea; [8]Mayo Clinic, Jacksonville, FL, USA; [9]University of Arizona, Tucson, AZ, USA; [10]GSK, Upper Providence, PA, USA; [11]GSK, Durham, NC, USA

Introduction: The B-cell maturation antigen (BCMA)-targeting antibody-drug conjugate (ADC) belantamab mafodotin (belamaf) contains the cytotoxic molecule cysteine-monomethyl auristatin-F (cys-mcMMAF). Belamaf has been extensively tested in clinical trials at 2.5 mg/kg every 3 weeks (Q3W) in patients (pts) with relapsed/refractory multiple myeloma (RRMM) and a glomerular filtration

at allo-HCT was complete response/very good partial response (n=18, 72%), partial response (PR) (n=6, 24%), and less than PR (n=1, 4%). Donor type distribution was as follows: MSD (n=12, 48%), MUD (n=7, 28%), and Haplo (n=6, 24%). Peripheral blood was the stem cell source in 23 (92%) patients. All patients engrafted. Cumulative incidence of acute GVHD grade II-IV and III-IV were 20% (95%CI, 38-70%) and 8% (1-23%), respectively. The 3-year cumulative incidence of NRM was 22% (95%CI: 3-52%) and of chronic GVHD 27% (95%CI: 11-47%). The 3-year OS, EFS, and GRFS were 74% (58-95%), 69% (52-91%), and 54% (37-79%), respectively. **Conclusions:** In this real-life cohort study, allo-HCT with the TBF conditioning regimen and GCHD prophylaxis with PTCy, sirolimus, and MMF showed encouraging results. It led to reduced acute and chronic GVHD incidence, improved GRFS, and favorable survival rates. These findings suggest that this combination holds promise as an effective treatment option for MM patients considered candidates for an allo-HCT.

Teclistamab versus Belgian real-world clinical practice in triple-class exposed relapsed and refractory multiple myeloma patients using adjusted comparison

Michel Delforge[1], Sébastien Anguille[2], Julien Depaus[3], Nathalie Meuleman[4], Ann Van De Velde[2], Isabelle Vande Broek[5], Joris Diels[6], Nichola Erler-Yates[7], Sébastien Van Causenbroeck[8], Kirsten Van Nimwegen[9], Sophie Vandervennet[8], Susanne Lub[10], Marie-Christiane Madeleine Vekemans[11]

[1]University of Leuven, Leuven, Belgium; [2]Antwerp University Hospital; [3]CHU UCL Namur; [4]Institut Jules Bordet; [5]AZ Nikolaas; [6]Janssen Pharmaceutica NV, Beerse, Belgium; [7]Janssen-Cilag GmbH; [8]Janssen-Cilag NV; [9]Janssen-Cilag B.V; [10]Janssen-Cilag; [11]Department of Internal Medicine, Université Catholique de Louvain (UCLouvain), Brussels, Belgium

Introduction: Triple-class exposed (TCE) relapsed and refractory multiple myeloma (RRMM) patients have a poor prognosis and limited treatment options. Teclistamab, a BCMA x CD3 bispecific antibody, is being studied in TCE RRMM patients in the single-arm phase 1/2 MajesTEC-1 trial. We assessed the relative effectiveness of teclistamab vs Belgian real-world clinical practice (RWCP) using individual patient data (IPD) from MajesTEC-1 and BELCOMM (Belgium Comparator study in Multiple Myeloma). **Methods:** An external control arm for MajesTEC-1 was created from TCE RRMM patients treated with RWCP therapies from the BELCOMM cohort, a retrospective Belgian patient cohort. Patients with an ECOG score 0 or 1, who received ≥ 3 prior lines of therapy (LOTs), and at least 1 subsequent active MM therapy after becoming TCE, were selected. IPD were available for MajesTEC-1 patients (cut-off March 2022) and RWCP patients in the BELCOMM cohort (cut-off May 2021). Patients with multiple LOTs initiated after fulfilling the inclusion criteria contributed multiple times to the analyses. Inverse probability weighting (IPW) was used to adjust for imbalances in baseline covariates, estimating the average treatment effect in the treated population. Comparative effectiveness of teclistamab vs RWCP was estimated for overall response rate (ORR), very good partial response or better (≥VGPR) rate, progression-free survival (PFS), time to next treatment (TTNT) and overall survival (OS). For the binary endpoints (ORR and ≥VGPR), weighted logistic regression was used to estimate the relative effect of teclistamab vs RWCP with odds ratios (OR) transformed into response-rate ratios (RR) and 95% confidence intervals (CI). For time-to event endpoints (PFS, TTNT and OS) weighted Cox proportional hazards regression was used to estimate hazard ratios (HR) and 95% CIs. **Results:** 165 patients (165 LOTs) from the MajesTEC-1 cohort and 112 patients (237 LOTs) from the BELCOMM cohort were included in the intention-to-treat (ITT) analyses. All adjusted comparative analyses demonstrated statistically significant results in favor of teclistamab across all endpoints. The RR for teclistamab vs RPWC for ORR and ≥VGPR were 2.31 [95% CI: 1.69, 3.15] and 5.97 [3.80, 9.37], respectively. Teclistamab patients were 2.3 and 6.0 times more likely to reach ORR and ≥VGPR, respectively. The HR for teclistamab vs RWPC were 0.39 [0.29, 0.52] for PFS, 0.35 [0.27, 0.47] for TTNT, and 0.55 [0.40, 0.76] for OS. Sensitivity analyses using multivariable logistic regression and Cox regression analysis were consistent with the main analyses. **Conclusions:** Teclistamab was associated with significantly superior effectiveness compared with treatments administered in RWCP in Belgian TCE RRMM patients for each measure of clinical effectiveness. Results were consistent across sensitivity analyses and confirm previous indirect comparisons vs other RWPC cohorts. These findings highlight teclistamab's clinical benefit as a novel and effective treatment in TCE RRMM patients.

Introduction: The B-cell maturation antigen (BCMA)-targeting antibody-drug conjugate (ADC) belantamab mafodotin (belamaf) contains the cytotoxic molecule cysteine-monomethyl auristatin-F (cys-mcMMAF). Belamaf has been extensively tested in clinical trials at 2.5 mg/kg every 3 weeks (Q3W) in patients (pts) with relapsed/refractory multiple myeloma (RRMM) and a glomerular filtration

rate (GFR) ≥30 mL/min. DREAMM-12 includes renally impaired pts (GFR < 30 mL/min) to provide belamaf dose recommendations for this population. **Methods:** In Part 1 of the ongoing DREAMM-12 study (NCT04398745), 2 groups of pts with RRMM (≥2 lines of prior therapy) were studied: Control Group 1, GFR ≥60 mL/min (normal/mild renal impairment [RI]); Group 2, GFR of 15–29 mL/min (severe RI). Pts were treated with belamaf (2.5 mg/kg Q3W). Endpoints were pharmacokinetics (PK) by non-compartmental analysis (primary), safety (secondary) and efficacy (exploratory). **Results:** Median (range) GFR was 84 mL/min (67–129) in Group 1 (10 pts) and 25 mL/min (20–28) in Group 2 (9 pts). Pts in both groups had received a median of 5 prior therapies. Median age was 61 years in Group 1 and 73 in Group 2. Median dose intensity was similar between groups. The PK population comprised 16 pts (n=8 per group) matched for body weight and albumin, with ≥80% PK collection at Cycle 1. PK analysis showed pts in Group 2 had lower geometric mean ADC plasma concentrations, total antibody and cys-mcMMAF than pts in Group 1. Exposures between groups were largely overlapping: differences were not considered clinically meaningful and were confirmed in a separate population PK analysis [1]. Urine PK analysis suggested renal elimination was not the primary route of cys-mcMMAF excretion (median < 10%). Adverse event (AE) incidence, severity and duration was similar between groups (any AE: Group 1, 100%; Group 2, 89%; Grade ≥3 AEs, Group 1, 70%; Group 2, 56%). There were 3 fatal AEs (Group 1, n=1, intestinal ischaemia; Group 2, n=2, pneumonia, intracerebral haemorrhage). The most common AEs by class (eye disorders: Group 1, 80%; Group 2, 56%), and most common serious AE (infections/infestations: Group 1, 20%; Group 2, 22%) showed no clinically meaningful differences across groups. Investigator assessed overall response rates (≥partial response) were n=5 of 10 pts in Group 1 vs n=4 of 9 pts in Group 2. **Conclusions:** No clinically meaningful PK, safety or efficacy differences were seen between pts with normal/mild RI (Group 1) and severe RI (Group 2): based on these data, no belamaf dose adjustment is necessary for pts with severe RI and GFR as low as 15 mL/min. Part 2 of this study will assess belamaf 2.5 mg/kg Q3W in pts with end stage renal disease (GFR < 15 mL/min) on and not on dialysis.

Introduction: To explore unmet need in patients with relapsed/refractory multiple myeloma (RRMM) refractory to lenalidomide (len), we report real-world attrition rates and treatment duration for len-refractory patients from the Flatiron multiple myeloma (MM) database who have had 1 prior line of therapy (LOT). **Methods:** Data from January 2016 to April 2022 were extracted from the Flatiron Health deidentified US electronic health records database. Eligible patients had len-refractory RRMM (defined as having a change in treatment within 60 days of last len therapy without len as a component of the immediate next LOT), 1 prior LOT including a proteasome inhibitor and an immunomodulatory drug, and an ECOG performance status < 2. After meeting inclusion criteria, patients were observed over their next 4 LOTs (LOT 2–5). Attrition rate was defined as the proportion of patients without a record of subsequent MM treatment. **Results:** From ~13,000 patients in the Flatiron database, we identified 561 at LOT 2 (first postinclusion LOT) with len-refractory RRMM. All patients received LOT 2. The attrition rate between LOT 2 and 3 was 43%, including 13% of patients who died and 30% with no subsequent treatment or lost follow-up. Noncumulative attrition rates after LOT 3 and 4 were 44% and 54%, respectively, including mortality rates of 13% and 15% at each LOT and an additional 31% and 39% of patients with no subsequent treatment or lost follow-up. Cumulatively, 85% patients (n=479) were lost to attrition by LOT 5, including 25% patients (n=141) who died and 60% patients (n=338) who received no subsequent treatment or were lost to follow-up. In LOT 2, 3, 4, and 5, a respective 38%, 14%, 8%, and 4% of the 561 patients received a National Comprehensive Cancer Network (NCCN)-recommended regimen (NCCN Guidelines for MM, Version 3. 2023) for len-refractory RRMM; and 41%, 26%, 14%, and 5% received other NCCN-endorsed RRMM regimens. In each of LOTs 2–5, 0.7–2.9% of the 561 patients participated in clinical trials. Median duration of each LOT was 4.5 month in LOT 2, 5.5 month in LOT 3, 4.9 month in LOT 4, and 5.2 month in LOT 5. **Conclusions:** Our findings of high attrition rates across LOTs (43–54%) for patients with len-refractory RRMM are consistent with previous results in patients with newly diagnosed MM (eligible and ineligible for transplant). In published literature, attrition rates were 21–57% after LOT 1 and 31–46% for the next 3 LOTs. The short median durations of treatment (each LOT < 6 month) observed in this analysis highlights the ineffectiveness of existing therapies. Together, these data underscore the need for more effective treatments early, before patients are lost to attrition, instead of reserving effective regimens for later LOTs.

rate (GFR) ≥30 mL/min. DREAMM-12 includes renally impaired pts (GFR < 30 mL/min) to provide belamaf dose recommendations for this population. **Methods:** In Part 1 of the ongoing DREAMM-12 study (NCT04398745), 2 groups of pts with RRMM (≥2 lines of prior therapy) were studied: Control Group 1, GFR ≥60 mL/min (normal/mild renal impairment [RI]); Group 2, GFR of 15–29 mL/min (severe RI). Introduction: Linvoseltamab is a fully human BCMA×CD3 bispecific antibody (Ab) that demonstrated encouraging efficacy and a generally manageable safety profile in patients (pts) with RRMM in a Phase (Ph) 1/2 dose-escalation/expansion study (LINKER-MM1; Lee et al. ASCO 2023). Here, we report a detailed analysis of pts who received linvoseltamab 200 mg, identified as the recommended dose. **Methods:** LINKER-MM1 (NCT03761108) enrolled adults with MM who progressed on/after ≥3 lines of therapy (LoT) including a proteasome inhibitor (PI), an immunomodulatory drug (IMiD), and an anti-CD38 Ab; the Ph 2 portion also included pts who were ≥triple-class (PI/IMiD/anti-CD38 Ab) refractory. In Ph 2, pts received linvoseltamab QW in Cycles 1–3 followed by Q2W dosing; dosing frequency was reduced to Q4W for pts who achieved ≥VGPR after Cycle 6. The Ph 2 primary endpoint was objective response rate (ORR). Key secondary endpoints included duration of response and minimal residual disease (MRD) status. **Results:** As of Feb 28, 2023, 117 pts had received linvoseltamab 200 mg (Ph 1, n=12; Ph 2, n=105): Median age, 70 yrs (range 37–91); Black/African American ethnicity, 17%; extramedullary plasmacytomas, 14%; high-risk cytogenetics, 36%; bone marrow plasma cells ≥50%, 22%. Pts had received a median of 5 (range 2–14) prior LoT, and 74% were ≥triple-class refractory. ORR was 71%, with 59% of pts achieving ≥VGPR and 30% achieving ≥CR, at a median duration of follow-up of 5.6 months (range 0.2–28.2). Median time to ≥VGPR and ≥CR was 1.87 months and 5.32 months, respectively. In pts who had prior BCMA-targeted therapy exposure with belantamab mafodotin (n=10), ORR was 60%. The median duration of ≥VGPR was not reached, and the probability of maintaining at least this level of response at 6/12 months was 89%/83%. The most common TEAEs (>30%) were cytokine release syndrome (CRS; 45% [Gr 3: 1%]), cough (33% [Gr ≥3: 0]), fatigue (32% [Gr ≥3: 0]), diarrhea (32% [Gr ≥3: 2%]), and neutropenia (32% [Gr ≥3: 31%]). CRS onset usually occurred on the day of dosing (median [range] time to first CRS onset from most recent dose, 14.8 h [0–177]), and resolved within 1 day (median [range] CRS duration, 16.5 h [1–144]); a temporal analysis to understand the relationship between tocilizumab use and recurrent CRS will be presented. ICANS (investigator-assessed) was reported in 6% (Gr ≥3: 3%) of pts. Infections occurred in 60% (Gr ≥3: 37%; Gr 5: 9%) of pts, with the most commonly identified infection types being pneumonia (17%; Gr ≥3: 14%), COVID-19 (12%; Gr ≥3: 5%) and upper respiratory tract infection (12%; Gr ≥3: 3%). **Conclusions:** Linvoseltamab 200 mg is efficacious and shows a generally manageable safety profile in triple-class exposed pts. We will present additional analyses, including the timing and durability of deep (≥VGPR) responses to linvoseltamab, and MRD status, which support further investigation at the recommended dose.

P-248

Real-world outcomes of triple-class exposed multiple myeloma patients by treatment experience: the assocaition of prior lines and penta-refractoriness with progression-free and overall survival

Aster Meche[1], Felix Rondeau[2], Ariane Faucher[2], Jinma Ren[1], Alexander Schepart[1], Patrick Hlavacek[1], James Farrell[1], Didem Aydin[1], Guido Nador[1], Marco DiBonaventura[1]

[1]Pfizer Inc; [2]Statlog

Introduction: Outcomes among patients (pts) with multiple myeloma (MM) who have been exposed to at least 1 proteasome inhibitor (PI), 1 immunomodulatory (IMiD) drug, and 1 anti-CD38 antibody (triple-class exposed [TCE]) are notoriously poor. The current study sought to quantify the underlying heterogeneity in clinical outcomes by stratifying TCE pts by their treatment experience using real-world data sources. **Methods:** TCE MM pts ≥18 years who had initiated a subsequent therapy (ie, index regimen) after this point were identified from two US electronic health record databases: COTA and Flatiron Health (FH). Within each database, pts were stratified by the number of lines of therapy (LOT) that they had been exposed to (< 4 vs ≥4, based on the distribution)

P-247

Efficacy and safety of linvoseltamab 200 mg in patients with relapsed/refractory multiple myeloma (RRMM): analysis of the LINKER-MM1 study

Introduction: Linvoseltamab is a fully human BCMA×CD3 bispecific antibody (Ab) that demonstrated encouraging efficacy and a generally manageable safety profile in patients (pts) with RRMM in a Phase (Ph) 1/2 dose-escalation/expansion study (LINKER-MM1; Lee et al. ASCO 2023). Here, we report a detailed analysis of pts who received linvoseltamab 200 mg, identified as the recommended dose. **Methods:** LINKER-MM1 (NCT03761108) enrolled adults with MM who progressed on/after ≥3 lines of therapy (LoT) including a proteasome inhibitor (PI), an immunomodulatory drug (IMiD), and an anti-CD38 Ab; the Ph 2 portion also included pts who were ≥triple-class (PI/IMiD/anti-CD38 Ab) refractory. In Ph 2, pts received linvoseltamab QW in Cycles 1–3 followed by Q2W dosing; dosing frequency was reduced to Q4W for pts who achieved ≥VGPR after Cycle 6. The Ph 2 primary endpoint was objective response rate (ORR). Key secondary endpoints included duration of response and minimal residual disease (MRD) status. **Results:** As of Feb 28, 2023, 117 pts had received linvoseltamab 200 mg (Ph 1, n=12; Ph 2, n=105): Median age, 70 yrs (range 37–91); Black/African American ethnicity, 17%; extramedullary plasmacytomas, 14%; high-risk cytogenetics, 36%; bone marrow plasma cells ≥50%, 22%. Pts had received a median of 5 (range 2–14) prior LoT, and 74% were ≥triple-class refractory. ORR was 71%, with 59% of pts achieving ≥VGPR and 30% achieving ≥CR, at a median duration of follow-up of 5.6 months (range 0.2–28.2). Median time to ≥VGPR and ≥CR was 1.87 months and 5.32 months, respectively. In pts who had prior BCMA-targeted therapy exposure with belantamab mafodotin (n=10), ORR was 60%. The median duration of ≥VGPR was not reached, and the probability of maintaining at least this level of response at 6/12 months was 89%/83%. The most common TEAEs (>30%) were cytokine release syndrome (CRS; 45% [Gr 3: 1%]), cough (33% [Gr ≥3: 0]), fatigue (32% [Gr ≥3: 0]), diarrhea (32% [Gr ≥3: 2%]), and neutropenia (32% [Gr ≥3: 31%]). CRS onset usually occurred on the day of dosing (median [range] time to first CRS onset from most recent dose, 14.8 h [0–177]), and resolved within 1 day (median [range] CRS duration, 16.5 h [1–144]); a temporal analysis to understand the relationship between tocilizumab use and recurrent CRS will be presented. ICANS (investigator-assessed) was reported in 6% (Gr ≥3: 3%) of pts. Infections occurred in 60% (Gr ≥3: 37%; Gr 5: 9%) of pts, with the most commonly identified infection types being pneumonia (17%; Gr ≥3: 14%), COVID-19 (12%; Gr ≥3: 5%) and upper respiratory tract infection (12%; Gr ≥3: 3%). **Conclusions:** Linvoseltamab 200 mg is efficacious and shows a generally manageable safety profile in triple-class exposed pts. We will present additional analyses, including the timing and durability of deep (≥VGPR) responses to linvoseltamab, and MRD status, which support further investigation at the recommended dose.

Real-world outcomes of triple-class exposed multiple myeloma patients by treatment experience: the assocaition of prior lines and penta-refractoriness with progression-free and overall survival

Aster Meche[1], Felix Rondeau[2], Ariane Faucher[2], Jinma Ren[1], Alexander Schepart[1], Patrick Hlavacek[1], James Farrell[1], Didem Aydin[1], Guido Nador[1], Marco DiBonaventura[1]

[1]Pfizer Inc; [2]Statlog

Introduction: Outcomes among patients (pts) with multiple myeloma (MM) who have been exposed to at least 1 proteasome inhibitor (PI), 1 immunomodulatory (IMiD) drug, and 1 anti-CD38 antibody (triple-class exposed [TCE]) are notoriously poor. The current study sought to quantify the underlying heterogeneity in clinical outcomes by stratifying TCE pts by their treatment experience using real-world data sources. **Methods:** TCE MM pts ≥18 years who had initiated a subsequent therapy (ie, index regimen) after this point were identified from two US electronic health record databases: COTA and Flatiron Health (FH). Within each database, pts were stratified by the number of lines of therapy (LOT) that they had been exposed to (< 4 vs ≥4, based on the distribution)

and, separately, whether they were penta-refractory (yes [PENTA+] vs no [PENTA-]). Differences across subgroups were evaluated with respect to patient (pt) characteristics (age, sex, ISS, ECOG, cytogenetics) and treatment history. Progression-free survival (PFS) and overall survival (OS) were compared across these subgroups using Kaplan-Meier methods. **Results:** N=686 TCE MM pts were included from the COTA database (52.3% had received ≥4 LOT [range 4-14]; 8.6% were PENTA+). Pts with fewer LOT were more likely to have high-risk cytogenetics (26.0% vs 16.7%) but the pt characteristics were otherwise generally similar to pts with ≥4 LOT. There was significant variability in the index treatment regimen, but daratumumab+pomalidomide+ dexamethasone (DPd) (13.5% and 9.7%, respectively) was the most common index regimen for both subgroups. No pt characteristic varied by PENTA status, though DPd was more common among those who were PENTA- (12.0% vs 6.8%). N=787 TCE MM pts were included from the FH database (41.7% had received ≥4 LOT; 4.4% were PENTA+). Pt characteristics did not vary by LOT group; DPd was the most common regimen for both < 4 LOT (7.3%) and ≥4 LOT (9.8%). PENTA+ pts were slightly younger (64.3 vs 67.8 yrs, p<.05) but otherwise similar to PENTA- pts. DPd (9.0%) was the most common regimen among PENTA- while carfilzomib+cyclophosphamide+dexamethasone (11.4%) was the most common regimen among PENTA+ pts. Pts with ≥4 LOT reported shorter PFS than pts with < 4 LOT (medians: 6.1 vs 17.8 months [COTA]; 7.3 vs 16.6 months [FH]; log-rank ps<.05) and OS (medians: 19.4 vs 24.5 months [COTA], log-rank p=.10; 14.2 vs 33.0 months [FH], log-rank p<.05). Similarly, pts who were PENTA+ had shorter PFS than PENTA- (medians: 4.7 vs 10.2 months [COTA]; 3.7 vs 14.8 months [FH]; log-rank ps<.05) and OS (medians: 14.3 vs 21.9 months [COTA], log-rank p<.05; 11.8 vs 21.3 months [FH], log-rank p=.21). **Conclusions:** Although TCE MM pts report poor outcomes overall, significant differences in real-world outcomes are observed based on their treatment histories. Pts with more prior LOTs or who were penta-refractory had significantly shorter PFS and OS, despite similar treatment regimens in their index line.

P-249

The association between age, performance status, frailty and outcomes in real-world clinical practice among patients with triple-class exposed multiple myeloma

Aster Meche[1], Felix Rondeau[2], Sarasa Johnson[2], Jinma Ren[1], Alexander Schepart[1], Patrick Hlavacek[1], James Farrell[1], Didem Aydin[1], Guido Nador[1], Marco DiBonaventura[1]

[1]Pfizer Inc; [2]Statlog

Introduction: Disease management in multiple myeloma (MM) among those with advanced age and poorer functioning can be particularly challenging (Grant et al 2023). The objective of the current study was to examine the extent to which patient outcomes vary by age, performance status based on the ECOG score, and frailty, based on a modified IMWG frailty index, among those who have already been exposed to at least 1 proteasome inhibitor, 1 immunomodulatory drug, and 1 anti-CD38 antibody (ie, triple-class exposed [TCE]). **Methods:** Patients ≥18 years with MM who initiated a subsequent therapy (ie, index regimen) after becoming TCE were identified through two US electronic health record databases (COTA and Flatiron Health). In each database, patients were stratified by age (< 65 vs ≥65; < 75 vs ≥75), ECOG score (< 2 vs ≥2), and frailty score (non-frail: < 2 vs frail: ≥2) based on a modified IMWG frailty index incorporating age, ECOG, and comorbidities. Differences across subgroups were evaluated with respect to patient characteristics (age, sex, ISS, cytogenetics) and treatment history. Progression-free survival (PFS) and overall survival (OS) were compared across these subgroups using Kaplan-Meier methods. **Results:** A total of N=686 TCE MM patients were included from the COTA database: 64.1% were ≥65 years (yrs), 27.6% were ≥75 yrs, 11.8% were ECOG≥2, and 25.5% were frail. Though median (m)PFS tended to be shorter for older and poorer functioning patients, PFS results were not statistically significantly different across all comparisons. However, patients ≥65 yrs had significantly shorter OS than patients < 65 yrs (mOS=17.6 vs 28.7 months, log-rank p<.05) and patients ≥75 yrs had significantly shorter OS than patients < 75 yrs (mOS=17.0 vs 24.1 months, log-rank p<.05). Similarly, ECOG≥2 and frail patients had significantly shorter (log-rank ps<.05) OS than ECOG< 2 and non-frail patients, respectively (mOS=8.1 vs 21.0 months; 12.7 vs 21.9 months). Results within the Flatiron database (N=787) were generally similar: 62.1% were ≥65 yrs, 28.8% were ≥75 yrs, 19.4% were ECOG≥2, and 40.9% were frail. PFS results were not statistically significantly different across all comparisons (log-rank p≥.05). As in the COTA database, patients ≥75 yrs had significantly shorter OS than patients < 75 yrs (mOS=17.5 vs 23.3 months, log-rank p<.05). Similarly, ECOG≥2 and frail patients had significantly shorter OS than ECOG< 2 and non-frail patients respectively (mOS=11.4 vs 25.0 months, log-rank p<.05; mOS=12.9 vs 27.4 months, log-rank p<.05). **Conclusions:** Older age, higher ECOG score, and being frail were generally not significantly predictive of shorter PFS, but they were predictive of shorter OS.

P-250

The relationship of extramedullary disease and high-risk cytogenetics on real-world outcomes among patients with triple-class exposed multiple myeloma

Aster Meche[1], Felix Rondeau[2], Francis Vekeman[2], Jinma Ren[1], Alexander Schepart[1], Patrick Hlavacek[1], James Farrell[1], Didem Aydin[1], Guido Nador[1], Marco DiBonaventura[1]

[1]Pfizer Inc; [2]Statlog

Introduction: Triple-class exposed (TCE) multiple myeloma (MM) patients who present with extramedullary disease (EMD) or high-risk cytogenetics can experience disproportionately poor outcomes. The current study sought to examine the real-world relationship between these disease attributes, treatment patterns, and future outcomes. **Methods:** Using two US electronic health record databases (COTA and Flatiron Health), MM patients ≥18

and, separately, whether they were penta-refractory (yes [PENTA+] vs no [PENTA-]). Differences across subgroups were evaluated with respect to patient (pt) characteristics (age, sex, ISS, ECOG, cytogenetics) and treatment history. Progression-free survival (PFS) and overall survival (OS) were compared across these subgroups using Kaplan-Meier methods. **Results:** N=686 TCE MM pts were included from the COTA database (52.3% had received ≥4 LOT [range 4-14]; 8.6% were PENTA+). Pts with fewer LOT were more likely to have high-risk cytogenetics (26.0% vs 16.7%) but the pt characteristics were otherwise generally similar to pts with ≥4 LOT. There was significant variability in the index treatment regimen, but daratumumab+pomalidomide+ dexamethasone (DPd) (13.5% and 9.7%, respectively) was the most common index regimen for both subgroups. No pt characteristic varied by PENTA status, though DPd was more common among those who were PENTA- (12.0% vs 6.8%). N=787 TCE MM pts were included from the FH database (41.7% had received ≥4 LOT; 4.4% were PENTA+). The relationship of extramedullary disease and high-risk cytogenetics on real-world outcomes among patients with triple-class exposed multiple myeloma

Aster Meche[1], Felix Rondeau[2], Francis Vekeman[2], Jinma Ren[1], Alexander Schepart[1], Patrick Hlavacek[1], James Farrell[1], Didem Aydin[1], Guido Nador[1], Marco DiBonaventura[1]

[1]Pfizer Inc; [2]Statlog

Introduction: Triple-class exposed (TCE) multiple myeloma (MM) patients who present with extramedullary disease (EMD) or high-risk cytogenetics can experience disproportionately poor outcomes. The current study sought to examine the real-world relationship between these disease attributes, treatment patterns, and future outcomes. **Methods:** Using two US electronic health record databases (COTA and Flatiron Health), MM patients ≥18

years who initiated a subsequent therapy (ie, index regimen) after becoming TCE (ie, exposed to ≥1 PI, ≥1 IMiD, ≥1 anti-CD38) between November 2015 and June 2022 (COTA)/August 2021 (Flatiron) were included. Within the COTA database, patients were stratified by the presence versus absence of EMD (EMD+ vs. EMD-) and high-risk cytogenetics (HRC) (defined based on the presence of t(4:14), t(14:16), or del17p [ie, HRC+] or the absence of all three [HRC-] at the point of index). Because EMD was not reliably captured in the Flatiron Health database, only HRC comparisons were made in that data source. Differences across subgroups were evaluated with respect to patient characteristics (age, sex, ISS, ECOG), and treatment history. Progression-free survival (PFS) and overall survival (OS) were compared across these subgroups using the Kaplan-Meier method. **Results:** Of the N=686 TCE MM patients included from the COTA database, 12.0% were EMD+ and 21.1% were HRC+. No demographic or disease characteristic differences were observed between subgroups. There was significant variability in treatment regimens with no regimen occurring in more than 13% of either subgroup. Daratumumab+pomalidomide+dexamethasone (DPd) was the most common for all subgroups (EMD+: 9.8%; EMD-: 11.8%; HRC+:13.8%; HRC-: 10.9%). Of the N=787 TCE MM patients included from the Flatiron database, 22.4% were HRC+. HRC+ patients were slightly younger (65.2 vs. 68.3 years, p<.05) but otherwise similar with respect to demographics and disease characteristics compared with HRC-. DPd was also the most common regimen for both HRC+ (6.3%) and HRC- (9.5%). In the COTA database, EMD+ patients reported directionally shorter PFS (median: 4.7 vs 9.9 months, log-rank p=.08) and significantly shorter OS compared with EMD- (median: 11.6 vs. 24.0 months, log-rank p<.05). HRC+ patients had directionally shorter PFS (COTA: median 8.3 vs. 9.5 months, log-rank p=.17; Flatiron: median 7.0 vs. 12.1, p=.09) but significantly shorter OS (COTA: 13.7 vs. 23.9 months, log-rank p<.05; Flatiron: 11.8 vs. 25.2 months, log-rank p<.05) across both data sources. **Conclusions:** Among TCE MM patients in the real world, the presence of EMD and HRC was significantly predictive of poorer OS. Trends indicating that these factors predict poorer PFS were observed as well, though studies with larger samples sizes might be required to detect significant effects.

Introduction: Multiple myeloma (MM) patients who have been exposed to at least 1 proteasome inhibitor, 1 immunomodulatory drug, and 1 anti-CD38 antibody (ie, triple-class exposed [TCE]) experience poor outcomes. This analysis examined the variation of real-world TCE outcomes as a function of ECOG performance status and number of prior lines of therapy (LOTs). **Methods:** Data from the Therapy Monitor-Multiple Myeloma (TM-MM) Germany registry were used, which includes approximately 8,000 patients (pts) with MM from a representative sample of >100 treating institutions. Pts were included in the analysis if they had physician-documented MM per IMWG diagnosis criteria, were TCE, and initiated a subsequent therapy after becoming TCE (ie, index date) between May 2016 and March 2022, allowing for a minimum 6-month follow-up window until the end of data availability (September 2022). Pts with smoldering disease or active plasma cell leukemia were excluded, as were pts who had received an investigational treatment line as part of a clinical trial. Eligible pts were stratified by clinical subgroups including ECOG score (0 vs 1 vs 2 vs 3-4) and the number of prior LOTs (< 4 vs ≥4). Using Kaplan-Meier estimates, progression-free survival (PFS), defined as time from index to progression (with initiation of the next treatment line as a proxy) or death due to any cause and overall survival (OS), defined as time from index until death due to any cause, were calculated. **Results:** A total of N=1,028 TCE pts were included in the analyses (median age=72.7 years [range: 44.1 to 94.2], 57.6% male. At the index date, 10.4% were high-risk based on the presence of t(4:14), t(14:16), and/or del17p (ie, genomic features based on R-ISS; though 77.0% of pts had unknown/unassessed cytogenetic risk); 10.1%, 44.6%, and 36.2% had ECOG scores of 0, 1, and 2, with the remaining 7.4% having an ECOG of 3 or 4. Pts had received a median of 3 prior LOTs with 35.8% being quad-exposed. Median PFS (mPFS) decreased with increasing ECOG score category: ECOG 0=11.7 months (95% confidence interval: 11.3 months, 12.1 months); ECOG 1=10.2 months (9.0, 11.4); ECOG 2=9.6 months (8.0, 10.6); and ECOG 3/4=7.8 months (5.9, 9.9). Similarly, shorter mPFS (5.8 months [5.0, 7.2] vs 11.0 months [10.4, 11.6] was observed for prior LOT≥4 and < 4, respectively). mOS also decreased with increasing ECOG score category: ECOG 0=not estimable (NE) (30.0, NE); ECOG 1=21.1 months (17.8, 27.0); ECOG 2=19.4 months (17.8, 24.7); ECOG 3/4=10.7 months (9.1, 14.6). Shorter mOS (8.7 months [7.0, 12.2] vs 24.3 months [21.3, 27.5]) was also observed for pts with ≥4 prior LOTs. **Conclusions:** Although TCE MM pts in Germany experience poor outcomes overall, this was particularly true for pts with higher ECOG scores and more prior LOTs. The results highlight the necessity to use all available therapeutic options in early lines of therapy.

Impact of belantamab mafodotin vs pomalidomide/low-dose dexamethasone treatment on health-related quality of life and vision-related functioning in patients with relapsed/refractory multiple myeloma

Meletios Dimopoulos[1], Katja Weisel[2], Vania Hungria[3], Sandhya Sapra[4], Neal Sule[4], Mary Li[4], Astrid McKeown[5], Gbenga Kazeem[5], Margaret Polinkovsky[6], Juliette Meunier[7], Angely Loubert[7], Laurine Bunod[7], Sue Perera[8], Brooke Currie[9]

years who initiated a subsequent therapy (ie, index regimen) after becoming TCE (ie, exposed to ≥1 PI, ≥1 IMiD, ≥1 anti-CD38) between November 2015 and June 2022 (COTA)/August 2021 (Flatiron) were included. Within the COTA database, patients were stratified by the presence versus absence of EMD (EMD+ vs. EMD-) and high-risk cytogenetics (HRC) (defined based on the presence of t(4:14), t(14:16), or del17p [ie, HRC+] or the absence of all three [HRC-] at the point of index). Because EMD was not reliably captured in the Flatiron Health database, only HRC comparisons were made in that data source. Differences across subgroups were evaluated with respect to patient characteristics (age, sex, ISS, ECOG), and treatment history. Progression-free survival (PFS) and overall survival (OS) were compared across these subgroups using the Kaplan-Meier method. **Results:** Of the N=686 TCE MM patients included from the COTA database, 12.0% were EMD+ and 21.1% were HRC+. No demographic or disease characteristic differences were observed between subgroups. There was significant variability in treatment regimens with no regimen occurring in more than 13% of either subgroup. Daratumumab+pomalidomide+dexamethasone (DPd) was the most common for all subgroups (EMD+: 9.8%; EMD-: 11.8%; HRC+:13.8%; HRC-: 10.9%). Of the N=787 TCE MM patients included from the Flatiron database, 22.4% were HRC+. HRC+ patients were slightly younger (65.2 vs. 68.3 years, p<.05) but otherwise similar with respect to demographics and disease characteristics compared with HRC-. DPd was also the most common regimen for both HRC+ (6.3%) and HRC- (9.5%). In the COTA database, EMD+ patients reported directionally shorter PFS (median: 4.7 vs 9.9 months, log-rank p=.08) and significantly shorter OS compared with EMD- (median: 11.6 vs. 24.0 months, log-rank p<.05). HRC+ patients had directionally shorter PFS (COTA: median 8.3 vs. 9.5 months, log-rank p=.17; Flatiron: median 7.0 vs. 12.1, p=.09) but significantly shorter OS (COTA: 13.7 vs. 23.9 months, log-rank p<.05; Flatiron: 11.8 vs. 25.2 months, log-rank p<.05) across both data sources. **Conclusions:** Among TCE MM patients in the real world, the presence of EMD and HRC was significantly predictive of poorer OS. Trends indicating that these factors predict poorer PFS were observed as well, though studies with larger samples sizes might be required to detect significant effects.

[1]National and Kapodistrian University of Athens; [2]University Medical Center of Hamburg-Eppendorf, Hamburg, Germany; [3]Department of Hematology, Clinica São Germano, São Paulo, Brazil; [4]GSK, Upper Providence, USA; [5]GSK, Stevenage, England, UK; [6]GSK, Durham, USA; [7]Modus Outcomes, Lyon, France; [8]GSK, London, UK; [9]GSK, Rockville, USA

Introduction: The Phase 3, open-label, randomised, DREAMM-3 trial (NCT04162210) assessed single-agent belantamab mafodotin (belamaf), an antibody-drug conjugate targeting BCMA, vs pomalidomide + low-dose dexamethasone (Pd) in adults with relapsed/refractory multiple myeloma (RRMM) at second relapse or later. Trends in health-related quality of life (HRQL) and vision-related functioning (VRF) in DREAMM-3 are reported. **Methods:** Patients (pts) were randomised (2:1) to belamaf or Pd and completed electronic pt-reported outcome measures including EORTC QLQ-C30 (fatigue, physical and role functioning, global health), EORTC MM module (QLQ-MY20, disease pain), and the Ocular Surface Disease Index (OSDI, impact of ocular adverse events of special interest on VRF) at baseline (BL) and every 3 weeks. Proportions of pts with meaningful deterioration from BL in EORTC scores (≥10-point change) and time to first meaningful deterioration in fatigue were assessed. Meaningful deterioration in VRF (≥12.5-point change) and subsequent improvements were analysed. All were post hoc analyses. **Results:** 325 patients with RRMM were enrolled (belamaf, n=218; Pd, n=107). Compared to Pd, lower proportions of pts on belamaf experienced meaningful deterioration from BL in fatigue, functioning (physical, role), and global health; this pattern was seen across most visits through Week 31 and was most notable and consistent for role functioning and fatigue. For worsening disease pain, no difference was noted between arms. Time to first meaningful deterioration in fatigue was significantly delayed (P< 0.01) for pts receiving belamaf compared with Pd (median 148 days vs 64). Among pts with BL and ≥1 post-BL OSDI assessment (n=262), meaningful VRF deterioration was seen in both belamaf (67%) and Pd (49%) arms. Median days to first meaningful VRF deterioration was 45 for belamaf vs 44.5 in Pd. Lack of improvement after meaningful deterioration was similar across arms (belamaf 11%, Pd 12%). Among 92 pts in the belamaf arm with ≥3 OSDI assessments after first meaningful VRF deterioration, 82 (89%) pts had meaningful improvement, including 75 who returned to within 12.5 points of BL VRF score (defined recovery range). Mean global health and functioning scores remained stable for pts receiving belamaf who experienced VRF deterioration over the study. **Conclusions:** This descriptive analysis suggests positive trends in HRQL outcomes for pts treated with belamaf vs Pd, including fewer pts experiencing meaningful HRQL deterioration related to this progressive disease, and significantly delayed worsening of fatigue in pts on belamaf. In line with previous studies (DREAMM-2 and -3), improvement following VRF deterioration showed that ocular issues resolved for most pts receiving belamaf within 3 months. Importantly, stable functioning scores and global health status were seen for pts receiving belamaf who experienced deterioration in VRF, suggesting vision changes did not impact pts' overall HRQL.

Real world data of safety and efficacy profile of daratumumab in relapsed/refractory multiple myeloma patients: low grade respiratory infections and high efficacy in all treatment lines

Vasiliki Douka[1], Eleni Paphianou[1], Chrysavgi Lalayanni[1], Sotiria Dimou-Besikli[1], Michail Iskas[1], Maria Papathanasiou[1], Chrysanthi Vadikoliou[1], Grigorios Salvaras[1], Vasiliki Kanava[1], Ioanna Sakellari[1]

[1]G Papanikolaou Hospital

Introduction: Duration of response in multiple myeloma (MM) patients has significantly ameliorated. Daratumumab is an approved treatment option in both first line and relapse-refractory (R/R) setting. The aim of our study is the efficacy and safety of daratumumab in R/R MM patients in daily practice. **Methods:** In a cohort of 29 patients, daratumumab combination regimens were administered in 15/7/4/3 in 2nd/3rd/4th and 5th treatment line. Daratumumab in combination with lenalidomide and dexamethasone (DRd) was administered in 8 patients, with pomalidomide and dexamethasone (DPd) in 6 patients, with bortezomib and dexamethasone (DVd) in 4 patients, with Carfilzomib and dexamethasone (DKd) in one patient, with dexamethasone only in 7 patients. One patient received D-VRd. The cohort consisted of male/female: 18/11 patients with median age 63 (41-77) years old, IgG/IgA/IgD/FLC/non secretory=14/3/1/8/3. ISS at diagnosis was: I/II/III=6/12/11 patients. Plasmacytoma was detected in 4 patients, 1 with extraosseous location and 7 patients had elevated serum LDH levels. Conventional karyotype and FISH were available in 24 and 14 patients respectively. Twenty patients had normal karyotype, 1 hyperdiploid, 3 complex. Regarding FISH, 5/14 patients had del17p, 2/14 del1p/add1q, 1/14 t(4;14), 2/14 t(11;14). Overall, 24/29 (83%) experienced a pulmonary infection adverse event. **Results:** Median PFS for patients in first relapse was not reached (3-49 months) and best response was CR/VGPR in 9/15 (60%) patients. All patients experienced a pulmonary infection adverse event, grade 3 requiring hospitalization in 2 patients and grade 2 in the rest. COVID-19 was detected in 7 patients. Nine patients developed neutropenia, grade 3/2/1=2/5/2 patients. Median PFS for patients beyond first relapse was 15 (1-60) months and best response was VGPR or better in 5/14 (36%). Nine out of 14 (64%) patients experienced a pulmonary infection adverse event, grade 2= 8/9 and only one grade 3. COVID-19 was detected in 4/14 (28%) patients. None of the COVID infected patients had fatal outcome or required ICU admission. Seven out of fourteen patients developed neutropenia grade 2. **Conclusions:** Daratumumab induced long and deep responses in all treatment lines. Even patients with multiple prior lines achieved durable responses. Although pulmonary infections were seen in the majority of patients, they were manageable with no fatalities.

ISS at diagnosis was: I/II/III=6/12/11 patients. Plasmacytoma was detected in 4 patients, 1 with extraosseous location and 7 patients had elevated serum LDH levels. Conventional karyotype and FISH were available in 24 and 14 patients respectively. Twenty patients had normal karyotype, 1 hyperdiploid, 3 complex. Regarding FISH, 5/14 patients had del17p, 2/14 del1p/add1q, 1/14 t(4;14), 2/14 t(11;14). Overall, 24/29 (83%) experienced a pulmonary infection adverse event. **Results:** Median PFS for patients in first relapse was not reached (3-49 months) and best response was CR/VGPR in 9/15 (60%) patients. All patients experienced a pulmonary infection adverse event, grade 3 requiring hospitalization in 2 patients and grade 2 in the rest. COVID-19 was detected in 7 patients. Nine patients developed neutropenia, grade 3/2/1=2/5/2 patients. Median PFS for patients beyond first relapse was 15 (1-60) months and best response was VGPR or better in 5/14 (36%). Nine out of 14 (64%) patients experienced a pulmonary infection adverse event, grade 2= 8/9 and only one grade 3. COVID-19 was detected in 4/14 (28%) patients. None of the COVID infected patients had fatal outcome or required ICU admission. Seven out of fourteen patients developed neutropenia grade 2. **Conclusions:** Daratumumab induced long and deep responses in all treatment lines. Even patients with multiple prior lines achieved durable responses. Although pulmonary infections were seen in the majority of patients, they were manageable with no fatalities.

Cardiac and hidden toxicity of carfilzomib in presence of cardiometabolic syndrome and early-stage heart failure with reduced ejection fraction

Panagiotis Efentakis[1], Aimilia Varela[2], Sofia Lamprou[1], Eleni-Dimitra Papanagnou[1], Michail Chatzistefanou[1], Andriana Christodoulou[1], Costantinos Davos[2], Maria Gavriatopoulou[3], Ioannis Trougakos[1], Meletios Dimopoulos[1], Ioanna Andreadou[1], Evangelos Terpos[3]

[1]National and Kapodistrian University of Athens; [2]Biomedical Research Foundation (BRFAA) of the Academy of Athens; [3]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece

Introduction: Cancer therapy-related Cardiovascular adverse events (CAEs) in presence of comorbidities, such as Cardiometabolic Syndrome (CMS) and Early-Stage Heart Failure with reduced Ejection Fraction (HFrEF), are in the spotlight of the Cardio-oncology guidelines, with proteasome inhibitors standing among anticancer therapies with most prominent cardiotoxicity. Carfilzomib (Cfz) indicated for relapsed/refractory multiple myeloma (MM), presents with serious CAEs. MM is often accompanied with coexisting comorbidities. However, Cfz use in MM patients with CMS or HFrEF is questionable. **Methods:** ApoE-/- and C57BL6/J male mice received 14 weeks High Fat Diet (HFD) for the establishment of CMS. C57BL6/J male mice underwent permanent LAD ligation for 14 days in order to establish Early-stage HFrEF. CMS- and HFrEF-burdened mice received Cfz for 2 consecutive days or for 6 days, on alternate days intraperitoneally (i.p.), whereas Control mice received Normal Saline (0.9%) at the same dose regimen i.p. Daily Metformin and Atorvastatin administrations were performed additionally to Cfz, as possible prophylactic interventions. Mice underwent complete echocardiography analysis, while proteasome activity, biochemical and molecular analyses were conducted. **Results:** CMS did not exacerbate Cfz Left Ventricular (LV) dysfunction, while Cfz led to metabolic complications, including decrease of fasting blood glucose and impairment of the lipid profile, in both CMS models. Cfz induced autophagy and Ca2+ homeostasis dysregulation, whereas Metformin and Atorvastatin prevented Cfz-mediated LV dysfunction and molecular deficits in the CMS-burdened myocardium. Early-stage HFrEF led to a depressed LV function and an increased PP2A activity. Cfz further increased myocardial PP2A activity, inflammation and Ca2+-cycling dysregulation. Met co-administration exerted an anti-inflammatory potential in the myocardium, without improving LV function. **Conclusions:** CMS and HFrEF seem to exacerbate Cfz's CAEs by presenting metabolism-related hidden toxicity and PP2A-related cardiac inflammation, respectively. Met retains its prophylactic potential in the presence of CMS, while mitigated inflammation and Ca2+ signalling dysregulation HFrEF myocardium.

Efficacy of a second autologous stem cell transplant for multiple myeloma and correlation with response to initial transplant: a single-center experience

Hamid Ehsan[1], Myra Robinson[1], Shebli Atrash[1], Ami Ndiaye[1], Jordan Robinson[1], Manisha Bhutani[2], Cindy Varga[1], Paul Eldridge[1], Jing Ai[1], Nilanjan Ghosh[1], Peter Voorhees[3], Barry Paul[1], Kristen Cassetta[1]

[1]Levine Cancer Institute, Atrium Health; [2]Division of Plasma Cell Disorders, Department of Hematologic Oncology & Blood Disorders, Levine Cancer Institute, Atrium Health, Charlotte, NC, USA; [3]Levine Cancer Institute, Atrium Health Wake Forest University School of Medicine

Introduction: High-dose melphalan (HDM) and autologous stem cell transplant (ASCT) has consistently been shown to improve depth of response and PFS in large phase 3 trials of myeloma patients. However, the role of a second (salvage) transplant (sASCT) for relapsed refractory multiple myeloma (RRMM) in the era of novel therapies is less clear. **Methods:** We retrospectively evaluated 43 RRMM patients who underwent a sASCT between Nov 2014 and June 2022 at our institution. **Results:** Median time between first and sASCT was 4.4 yrs. The median follow-up from MM diagnosis was 7.6 yrs, and from sASCT was 2.9 yrs. The majority of pts had standard risk cytogenetics (77%). The most common cytogenetic abnormalities at diagnosis were monosomy 13 (35%) followed by t(11;14), del 17p, and gain/amp of 1q21 (each 14%). The most common induction regimen was RVD (51%) followed by CyBorD (11.6%). Most patients (76.7%) received maintenance therapy after initial transplant with IMiD (72%), PI (15%) and doublet (12.4%) regimens being most common. After sASCT the majority of patients (85.4%) received maintenance with IMiD (45%), triplet (17%), PI (14%), daratumumab (8.6%), doublets (8.6%), or Selinexor (5.7%). The median total number of lines of therapies was 5 (3-15). Two patients (4.7%) succumbed to sASCT-related mortality, with 41 patients being response-evaluable. Responses were deep, with most patients achieving a CR or sCR (70%), or VGPR (18.6%) as best response after sASCT, while only three patients (7 %) achieved 4 years (n=10) also supported this association (log-rank test p4 years of PFS1 was 4.3 years. Using cox proportional hazards models, the risk of progression or death after sASCT in those with PFS1 4 years. **Conclusions:** Our data suggest a significant benefit for sASCT in RRMM patients, especially those that achieved at least a 4-year PFS from their first ASCT. Additionally, most patients achieved deep responses (CR or sCR). While our dataset is small and only represents a single-center experience, it implies that even in the era of novel therapies such as CAR-Ts and bispecific antibodies, there remains a role for sASCT in select patients.

Initial report of a single institution experience with teclistamab for relapsed or refractory multiple myeloma including prior BCMA

Beth Faiman[1], Danai Dima[1], Marissa Duco[1], Mikhaila Rice[1], Joslyn Rudoni[1], Faiz Anwer[1], Jack Khouri[1], Sandra Mazzoni[1], Shahzad Raza[1], Christy Samaras[1], Louis Williams[1], Jason Valent[1]

[1]Cleveland Clinic Taussig Cancer Institute

Introduction: Despite the rapidly evolving treatment armamentarium, multiple myeloma (MM), remains an incurable cancer. Teclistamab (TEC) is the first CD3 x BCMA, T-cell redirecting bispecific antibody indicated for the treatment of adult patients (pts) with relapsed or refractory MM (RRMM). Unfortunately, pts who received TEC in clinical trials (CT) are not representative of the real-world population. Here, we describe our initial experience among RRMM pts who received TEC at our institution from Dec 2022 to May 2023. **Methods:** This retrospective study included 26 pts with a confirmed diagnosis of MM who received TEC outside of a CT. Descriptive analyses were performed for baseline characteristics. The 2016 IMWG criteria were used to assess disease response and/or refractoriness to prior LOT. All pts were admitted to the hospital for TEC step-up doses and mandatory 48 hours of observation post-administration. All pts were given acyclovir and sulfamethoxazole-trimethoprim prophylaxis, or an alternative. **Results:** The median age of our cohort was 64 (range 45-75) yrs; 54% were females and 73% were Caucasian. The median number of prior LOT were seven (range 4-17), including nine (38%) pts with previous anti-BCMA (idecabtagene vicleucel) and one belantamab. One hundred percent and 92% of pts had the triple and penta-refractory disease, respectively. Ten (38%) pts had prior HSCT. Twenty-two (85%) pts developed cytokine release syndrome (CRS), which in most cases was mild (95% grade 1-2, 5% grade 3, 0% grade 4-5); of these 22 pts, 18 (82%) required tocilizumab (median number of total doses was one) and eight (36%) steroids. The most common CRS presentation was fever (91%), followed by hypoxia (9%) and hypotension (4.5%). TEC led to immune effector cell-associated neurotoxicity syndrome (ICANS) in five (19%) pts during the step-up period (100% grade 1-2); of them, 4 had CRS and 3 received steroids. Only seven pts experienced infections during the step-up period, of whom two had severe infections requiring intravenous (IV) therapies (COVID-19 infection treated with remdesivir, septic arthritis treated with IV antibiotics). For efficacy analysis, one pt was excluded due to recurrent ICANS with following doses mandating TEC discontinuation. After a median follow-up of 2.5 months, the best responses achieved were: four (16%) pts achieved complete response, five (20%) very good partial response, six (24%) partial response, four (16%) had stable disease, while three (12%) progressed and three (12%) died without achieving any response. Eventually, six (24%) pts progressed and four (16%) died. **Conclusions:** TEC is a promising therapy for pts with RRMM including those with prior BCMA exposure. Cytopenias and infections were reported but not significantly different from prior studies. No new safety signals were identified. These initial findings support the safety and efficacy of TEC in BCMA naïve and exposed pts and early anti-IL6 therapy to prevent escalation of CRS. Analysis of long-term outcomes is ongoing.

P-257

Real-world treatment patterns and clinical outcomes among patients with triple-class exposed (TCE) multiple myeloma (MM)

Rafael Fonseca[1], Jennifer Harper[2], Hoa Le[2], Alex Fu[2,3], Saurabh Patel[4], Bingcao Wu[2], Xinke Zhang[2]

[1]Division of Hematology/Oncology, Mayo Clinic, Phoenix, AZ, USA; [2]Janssen Scientific Affairs, LLC; [3]Georgetown University Medical Center, Washington, DC, USA; [4]Janssen US Oncology Medical Affairs, Janssen Pharmaceuticals

Introduction: Despite the advancements in available therapeutics for MM, MM remains an incurable disease, and most patients relapse and require further treatment. Patients who are TCE to immunomodulatory drugs, proteasome inhibitors, and anti-CD38 monoclonal antibodies have particularly high unmet needs. With rapid treatment landscape changes, the aim of this study is to describe characteristics, treatment patterns, and clinical outcomes of these patients in recent years. **Methods:** Patients with MM who started subsequent line of treatment (LOT) after they were TCE from July 03, 2019 (Selinexor approval date) to December 31, 2020 were selected from the Komodo Healthcare Map—a US claims dataset and were followed until the earliest of death, last claim, or end of study period (June 30, 2021). The primary analysis included patients with a subsequent LOT after becoming TCE. Patients who were post TCE with 4+ PLs and quadruple-class exposed (QCE; TCE + exposed to B-cell maturation antigen targeted drug) were also analyzed. Index date was defined as LOT start date after each exposure definitions. Descriptive statistics were reported for patient characteristics and treatment patterns. Clinical outcomes such as time to treatment discontinuation or death (TTD), and time to next treatment or death (TTNT) were estimated using the Kaplan-Meier method. Here we reported data for TCE and TCE with 4+ prior PLs; data for QCE cohort will be presented in the future. **Results:** A total of 1,704 TCE patients were included, among whom 1,072 had 4+ PLs. For TCE and TCE with 4+ PLs cohorts, the mean (median) ages were 64.6 (64.0) and 64.9 (64.0), and 46.6% and 47.4% were females, respectively. The mean (median) number of prior LOTs before index date were 3.9 (4.0) and 4.7 (4.0), respectively. Most patients who were TCE and TCE with 4+ PLs were exposed to daratumumab (D; 99.9% and 99.8%), lenalidomide (85.6% and 86.4 %), and bortezomib (84.2 % and 83.0%) before index date. The most common post-TCE treatments were pomalidomide (P)- (36.0%), D- (35.0%), and carfilzomib (K)- (33.7%) based regimens. Similarly, the most common post-TCE with 4+ PLs treatments were P- (33.8%), K- (33.8%), and D- (30.5%) based regimens. At the regimen level, D+P±dexamethasone was the most commonly used post-index regimen (8.0% and 6.7% for TCE and TCE with 4+ PLs, respectively). The median TTD (months) were 5.8 (95% CI 5.4-6.5) for TCE and 5.1 (95% CI 4.8-5.6) for TCE with 4+ PLs, while the median TTNT (months) were 8.4 (95% CI 7.9-9.4) for TCE and 7.1 (95% CI 6.7-7.8) for TCE with 4+ PLs. **Conclusions:** These

Here we reported data for TCE and TCE with 4+ prior PLs; data for QCE cohort will be presented in the future. **Results:** A total of 1,704 TCE patients were included, among whom 1,072 had 4+ PLs. For TCE and TCE with 4+ PLs cohorts, the mean (median) ages were 64.6 (64.0) and 64.9 (64.0), and 46.6% and 47.4% were females, respectively. The mean (median) number of prior LOTs before index date were 3.9 (4.0) and 4.7 (4.0), respectively. Most patients who were TCE and TCE with 4+ PLs were exposed to daratumumab (D; 99.9% and 99.8%), lenalidomide (85.6% and 86.4 %), and bortezomib (84.2 % and 83.0%) before index date. The most common post-TCE treatments were pomalidomide (P)- (36.0%), D- (35.0%), and carfilzomib (K)- (33.7%) based regimens. Similarly, the most common post-TCE with 4+ PLs treatments were P- (33.8%), K- (33.8%), and D- (30.5%) based regimens. At the regimen level, D+P±dexamethasone was the most commonly used post-index regimen (8.0% and 6.7% for TCE and TCE with 4+ PLs, respectively). The median TTD (months) were 5.8 (95% CI 5.4-6.5) for TCE and 5.1 (95% CI 4.8-5.6) for TCE with 4+ PLs, while the median TTNT (months) were 8.4 (95% CI 7.9-9.4) for TCE and 7.1 (95% CI 6.7-7.8) for TCE with 4+ PLs. **Conclusions:** These

findings demonstrate that in the real-world, patients have limited treatment options after TCE and are often retreated with the same therapies or therapies in the same classes. Patients who were TCE discontinued treatment and moved on to next treatment shortly after initial treatment. These outcomes were even shorter for those with 4+ PLs. The findings highlight the continued need for effective treatments for heavily treated patients with MM.

[1]University Hospital Split; [2]University Hospital Centre Zagreb; [3]School of Medicine, University of Zagreb; [4]Clinical Hospital Merkur School of Medicine, University of Zagreb; [5]University Hospital Dubrava; [6]University Hospital Centre Sestre Milosrdnice; [7]University Hospital Centre Osijek; [8]Clinical hospital Centre Rijeka, Faculty of Medicine, University of Rijeka; [9]General Hospital "dr. Josip Benčević" Slavonski Brod; [10]General Hospital Zadar; [11]General Hospital Šibenik; [12]General Hospital Pula; [13]General Hospital Čakovec; [14]General Hospital Dubrovnik; [15]Clinical Hospital Sv. Duh

Introduction: Use of carfilzomib in treatment of multiple myeloma (MM) brought significant improvements in patient's outcomes, predominantly in relapse/refractory (RR) settings but also in the newly diagnosed. Outcomes from clinical trials are better than outcomes reported in real-world evidence (RWE) data. Our objective was to analyse data for RR multiple myeloma patients treated with carfilzomib and to compare it with those reported in literature (both RWE and clinical trials). **Methods:** A retrospective analysis of outcomes in RRMM patients treated with carfilzomib, in combination with lenalidomide and dexamethasone (KRd) or dexamethasone alone (Kd), in 12 Croatian hematology centres in the period between June 2019 and February 2023 was performed (carfilzomib available and reimbursed since June 2019). **Results:** 119 patients with RR myeloma were included. Median age at the start of carfilzomib treatment for the whole group was 67 years (range 45 – 83). There were 61 male and 58 female patients. Median number of previous lines of therapies was 3 (range 2 – 8). 70 patients (59%) were previously treated with autologous stem cell transplantation (ASCT) in the first line of treatment and 3 patients also underwent allogeneic stem cell transplant. In the KRd group 84 patients (100%) were bortezomib exposed, 25 (30%) lenalidomide exposed and 23 (27%) daratumumab exposed. In the Kd group 35 patients (100%) were bortezomib and lenalidomide expose, while 25 (71%) were also daratumumab exposed. Only 12 (10%) and 10 (8%) of patients were exposed to ixazomib and pomalidome, respectively. KRd was choice of therapy in 84 patients (71%) and Kd in 35 patients (29%). In the KRd group overall response rate (better or equal to partial response; PR) was 63%, while in the Kd group response rate was 43%. Median follow up was 11 months in both groups. Median progression free survival (PFS) was 13.6 months in the KRd group and only 4 months in the Kd group. But, analyzing only patients treated with KRd in the 2nd line, median PFS was 24 months. Overall survival (OS) was 25 months in the KRd group (1 year OS 67%) and OS in the Kd group was 8 months (1 year OS 26%). 73% of patients in the KRd group had anemia, 44% neutropenia and 71% thrombocytopenia. In the Kd group, 89% had anemia, 40% neutropenia and 83% thrombocytopenia. Infective complications were reported in 49% of patients in the KRd group and 37% in the Kd group. During follow up 73 patients died (36 in the KRd and 25 in the Kd group). **Conclusions:** Our analysis confirms efficacy of carfilzomib in RR MM patients with acceptable toxicities. Our results differ significantly from results reported in clinical trials. Looking at the data for KRd in 2nd line only, results are similar to those in clinical trials. These differences in patient's outcomes are possibly due to differences in patient's characteristics. Similar results were reported in RR MM group of patients by other RWE data.

Targeting ubiquitin chains with cyclic peptides for the treatment of multiple myeloma

Dima Ghannam-Shahbari[1], Ashraf Brik[2]

[1]UB-Therapeutics; [2]Technion

Introduction: Recent research has uncovered small, non-proteinogenic cyclic peptides that tightly bind Lys48-linked ubiquitin chains. These peptides inhibit deubiquitinases and the proteasome, leading to apoptosis in vitro and attenuating tumor growth in vivo. This breakthrough highlights the potential of non-proteinogenic cyclic peptides as promising anti-cancer agents that target ubiquitin chains. **Methods:** Pre-Formulation Study, Apoptosis Assay, XTT Assay, PK Study, Analytical Development Assay, MTD Assay, In Vivo Efficacy Study **Results:** The study focuses on the development of novel cyclic peptides that have potential anti-cancer therapeutic properties. These peptides, which are small and contain non-proteinogenic amino acids, specifically bind to Lys48-linked ubiquitin chains. By blocking deubiquitinases and the proteasome, they induce apoptosis in cancer cells and inhibit tumor growth both in vitro and in vivo. Unlike traditional proteasome inhibitors, these cyclic peptides disrupt the recognition and degradation of ubiquitinylated proteins, offering a different mechanism of action that may overcome resistance associated with direct proteasome inhibitors. These cyclic peptides effectively inhibited Ub-dependent proteolysis, could enter cells, and induced the accumulation of Ub-conjugates. In vitro studies demonstrated their ability to inhibit the cleavage of K48Ub4 by a specific deubiquitinating enzyme and the degradation of K48Ub4-tagged proteins by the proteasome. Moreover, the cyclic peptides were internalized by live cells, induced

findings demonstrate that in the real-world, patients have limited treatment options after TCE and are often retreated with the same therapies or therapies in the same classes. Patients who were TCE discontinued treatment and moved on to next treatment shortly after initial treatment. These outcomes were even shorter for those with 4+ PLs. The findings highlight the continued need for effective treatments for heavily treated patients with MM.

Josip Benčević" Slavonski Brod; [10]General Hospital Zadar; [11]General Hospital Šibenik; [12]General Hospital Pula; [13]General Hospital Čakovec; [14]General Hospital Dubrovnik; [15]Clinical Hospital Sv. Duh

Introduction: Use of carfilzomib in treatment of multiple myeloma (MM) brought significant improvements in patient's outcomes, predominantly in relapse/refractory (RR) settings but also in the newly diagnosed. Outcomes from clinical trials are better than outcomes reported in real-world evidence (RWE) data. Our objective was to analyse data for RR multiple myeloma patients treated with carfilzomib and to compare it with those reported in literature (both RWE and clinical trials). **Methods:** A retrospective analysis of outcomes in RRMM patients treated with carfilzomib, in combination with lenalidomide and dexamethasone (KRd) or dexamethasone alone (Kd), in 12 Croatian hematology centres in the period between June 2019 and February 2023 was performed (carfilzomib available and reimbursed since June 2019). **Results:** 119 patients with RR myeloma were included. Median age at the start of carfilzomib treatment for the whole group was 67 years (range 45 – 83). There were 61 male and 58 female patients. Median number of previous lines of therapies was 3 (range 2 – 8). 70 patients (59%) were previously treated with autologous stem cell transplantation (ASCT) in the first line of treatment and 3 patients also underwent allogeneic stem cell transplant. In the KRd group 84 patients (100%) were bortezomib exposed, 25 (30%) lenalidomide exposed and 23 (27%) daratumumab exposed. In the Kd group 35 patients (100%) were bortezomib and lenalidomide expose, while 25 (71%) were also daratumumab exposed. Only 12 (10%) and 10 (8%) of patients were exposed to ixazomib and pomalidome, respectively. KRd was choice of therapy in 84 patients (71%) and Kd in 35 patients (29%). In the KRd group overall response rate (better or equal to partial response; PR) was 63%, while in the Kd group response rate was 43%. Median follow up was 11 months in both groups. Median progression free survival (PFS) was 13.6 months in the KRd group and only 4 months in the Kd group. But, analyzing only patients treated with KRd in the 2nd line, median PFS was 24 months. Overall survival (OS) was 25 months in the KRd group (1 year OS 67%) and OS in the Kd group was 8 months (1 year OS 26%). 73% of patients in the KRd group had anemia, 44% neutropenia and 71% thrombocytopenia. In the Kd group, 89% had anemia, 40% neutropenia and 83% thrombocytopenia. Infective complications were reported in 49% of patients in the KRd group and 37% in the Kd group. Ipilimumab after CD34-selected allogeneic stem cell transplantation (Allo HCT) for patients with relapsed/refractory multiple myeloma (RRMM)

Arnab Ghosh[1], Katherine Nagel[1], Kinga Hosszu[1], Ambika Datta[1], Christina Thompson[1], Khayla Levia[1], Alyssa Kamrowski[1], Devin McAvoy[1], David Chung[2], Heather Landau[2], Michael Scordo[1], Sergio Giralt[1], Gunjan Shah[1]

[1]Memorial Sloan Kettering Cancer Center, New York City NY, USA; [2]Bone Marrow Transplant and Cellular Therapy, Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: Despite recent advances in the therapeutic landscape of multiple myeloma (MM), a subgroup of patients with poorer than expected outcomes, remains at a high risk of rapid progression and death. Allogeneic hematopoietic cell transplantation (alloHCT) is considered for select patients in this subgroup with some success. Immune checkpoint blockade (ICB) has the theoretical potential to enhance the effectiveness of the alloHCT, but concerns of an unrestrained immune system causing graft versus host disease (GVHD) or allograft rejection has tempered the enthusiasm for testing these strategies to prevent or delay relapse after alloHCT. Given the lower probability of GVHD with CD34+selected alloHCT, we explored if adding ipilimumab (ipi), a CTLA-4 blocking antibody after CD34+selected alloHCT would be safe and effective in a phase I trial. **Methods:** Patients with RRMM in remission who had a 10/10 matched donor underwent conditioning with busulfan, melphalan, fludarabine, and rabbit ATG followed by an ex-vivo CD34+selected alloHCT. If in remission at day 100, patients then received ipi 3 mg/kg every 3 weeks for 4 doses followed by once every 3 months for 4 doses unless limited by DLT or disease relapse. Preventive and supportive care was as per institutional standards. The trial was approved by MSK institutional review board. **Results:** Between July 2021-July 2022, three patients enrolled prior to study closure for slow enrollment; 1 of these patients progressed prior to day 100 and was not eligible for treatment with ipi. The 2 patients who received ipi were male and aged 61 and 63. Patient 1 had 8 prior lines of treatment including 2 autologous HCT and patient 2 having 9 prior lines including 2 autologous HCTs and BCMA CAR T cells. Patient 1 received 5 doses of ipi before progressing at 309 days after alloHCT. Patient 2 received 3 doses of ipi prior to progression at 160 days after alloHCT. Neither of the two patients had GVHD or rejection of allograft. Patient 1 developed an ipi-associated rash that resolved with topical steroids and pericarditis related to a parainfluenza respiratory infection. We performed high-dimensional multicolor flow cytometry of peripheral blood and bone marrow before and after alloHCT, that showed expansion of T cells after alloHCT. At time points closer to relapse there were increased myeloid-derived suppressor cells and numbers of PD-1 expressing T cells. **Conclusions:** Our study suggests that ICB with ipi can be used after CD34+selected alloHCT without GVHD or allograft rejection in select patients. Further studies are needed to understand if the expanding T cell subsets participate in graft versus myeloma effects and into mechanisms that affect the durability of ICB therapy. Our trial underscores the significance of meticulous patient selection for ICB after alloHCT as a strategy to delay relapse of MM in platforms with low GVHD potential.

Comparison of different cutoffs of time from last drug exposure to disease progression for defining drug refractoriness in multiple myeloma

Utkarsh Goel[1], Charalampos Charalampous[1], Prashant Kapoor[1], Moritz Binder[1], Francis Buadi[1], David Dingli[1], Angela Dispenzieri[1], Amie Fonder[1], Morie Gertz[1], Wilson Gonsalves[1], Suzanne Hayman[1], Miriam Hobbs[1], Yi Hwa[1], Taxiarchis Kourelis[1], Martha Lacy[1], Nelson Leung[1], Yi Lin[1], Rahma Warsame[1], Robert Kyle[1], Vincent Rajkumar[1], Shaji Kumar[1]

[1]Mayo Clinic

Introduction: Defining refractoriness to specific drugs/ drug classes is important for determining eligibility for clinical trials and to compare results across studies in multiple myeloma (MM). As such, MM that is nonresponsive or progresses within 60 days of last therapy is currently considered to be refractory to that therapy. We hypothesized that subgroups of MM that typically exhibit faster response/ relapse kinetics (e.g., high risk MM) might require different intervals from last exposure for defining refractoriness, as compared to the current 60 days definition. **Methods:** We retrospectively reviewed all newly diagnosed MM patients (pts) at our institute between January 2004 and December 2018 who experienced disease progression with first line lenalidomide (Len) containing regimens, and subsequently received another Len containing regimen at any time during the disease course. We collected the time duration from last Len dose to first disease progression, and assigned 30 days, 60 days, and 120 days as cut-offs for defining Len refractoriness. We then assessed progression free survival (PFS) for next line therapy and the next Len containing line of therapy using Kaplan Meier and Cox models and used Harrell's Concordance Index (C) to measure the performance of different models. **Results:** A total of 202 pts were included. Overall, 43%, 39%, and 18% pts were International Staging System Stage I, II, and III; 32% pts had high risk FISH as per mSMART. For Len refractory vs not refractory pts,

apoptosis in cancer cell lines, and showed anti-cancer activity in vivo.The cyclic peptide Ub4a displayed stability in human plasma for multiple days, with a half-life of 60 hours, suggesting its potential for therapeutic applications. Overall, the study highlights the promising therapeutic potential of cyclic peptides as a novel approach for cancer treatment by targeting ubiquitin protein chains. **Conclusions:** This comprehensive investigation encompassed pre-formulation characterization, assessment of apoptotic activity, cell viability inhibition, pharmacokinetic profiling, analytical method development, determination of MTD, and evaluation of in vivo efficacy. At time points closer to relapse there were increased myeloid-derived suppressor cells and numbers of PD-1 expressing T cells. **Conclusions:** Our study suggests that ICB with ipi can be used after CD34+selected alloHCT without GVHD or allograft rejection in select patients. Further studies are needed to understand if the expanding T cell subsets participate in graft versus myeloma effects and into mechanisms that affect the durability of ICB therapy. Our trial underscores the significance of meticulous patient selection for ICB after alloHCT as a strategy to delay relapse of MM in platforms with low GVHD potential.

Comparison of different cutoffs of time from last drug exposure to disease progression for defining drug refractoriness in multiple myeloma

Utkarsh Goel[1], Charalampos Charalampous[1], Prashant Kapoor[1], Moritz Binder[1], Francis Buadi[1], David Dingli[1], Angela Dispenzieri[1], Amie Fonder[1], Morie Gertz[1], Wilson Gonsalves[1], Suzanne Hayman[1], Miriam Hobbs[1], Yi Hwa[1], Taxiarchis Kourelis[1], Martha Lacy[1], Nelson Leung[1], Yi Lin[1], Rahma Warsame[1], Robert Kyle[1], Vincent Rajkumar[1], Shaji Kumar[1]

[1]Mayo Clinic

Introduction: Defining refractoriness to specific drugs/ drug classes is important for determining eligibility for clinical trials and to compare results across studies in multiple myeloma (MM). As such, MM that is nonresponsive or progresses within 60 days of last therapy is currently considered to be refractory to that therapy. We hypothesized that subgroups of MM that typically exhibit faster response/ relapse kinetics (e.g., high risk MM) might require different intervals from last exposure for defining refractoriness, as compared to the current 60 days definition. **Methods:** We retrospectively reviewed all newly diagnosed MM patients (pts) at our institute between January 2004 and December 2018 who experienced disease progression with first line lenalidomide (Len) containing regimens, and subsequently received another Len containing regimen at any time during the disease course. We collected the time duration from last Len dose to first disease progression, and assigned 30 days, 60 days, and 120 days as cut-offs for defining Len refractoriness. We then assessed progression free survival (PFS) for next line therapy and the next Len containing line of therapy using Kaplan Meier and Cox models and used Harrell's Concordance Index (C) to measure the performance of different models. **Results:** A total of 202 pts were included. Overall, 43%, 39%, and 18% pts were International Staging System Stage I, II, and III; 32% pts had high risk FISH as per mSMART. For Len refractory vs not refractory pts,

the median PFS for next Len containing therapy was 10 months (95% CI: 6-13) vs 31 months (95% CI: 22-40) using a 30-days cutoff, and 10 months (95% CI: 6-13) vs 32 months (95% CI: 25-43) using 60-days and 120-days cutoffs (p< 0.001 for all). In the high-risk subgroup: for Len refractory vs not refractory pts, the median PFS for next Len containing therapy was 5 months (95% CI: 4-10) vs 41 months (95% CI: 19-NR) using a 30-days cutoff, and 5 months (95% CI: 4-7) vs 42 months (95% CI: 25- NR) using 60-days and 120-days cutoffs (p< 0.001 for all). Harrell's C (95% CI) for 30-days, 60-days, and 120-days cutoffs were 0.605 (0.564-0.646), 0.637 (0.598-0.676), and 0.636 (0.597-0.675) respectively. In the high-risk subgroup, Harrell's C for 30-days, 60-days, and 120-days cutoffs were 0.684 (0.613-0.755), 0.708 (0.641-0.775), and 0.708 (0.641-0.775) respectively. Similar trends were observed for all pts and high-risk MM pts for PFS with 2nd line therapy as well. **Conclusions:** We did not find an improvement in separation of survival curves or Harrell's C when using 30 days or 120 days as cutoffs for defining refractoriness, as compared to 60 days. The current 60 days cutoff from last drug exposure to disease progression functions well for defining refractoriness to MM drugs.

[1]Mayo Clinic

Introduction: Patients (pts) with multiple myeloma (MM) typically receive several different regimens, with the disease eventually becoming refractory to most of the included drugs. For late-line MM refractory to most available therapies, retreatment with a drug that the disease had earlier become refractory to might be one option. In this study we assessed the patterns of care and clinical outcomes of retreatment with previously refractory drugs in pts with MM **Methods:** We reviewed 1141 MM pts at our institute who started a new line of therapy for disease progression after January 2015. Of these, 315 pts received a drug that their disease had progressed on previously (index drug) and were included in the study. We collected the duration of initial regimen with index drug and the time gap between last dose of initial regimen and start of retreatment. We then assessed the best response with retreatment according to the IMWG criteria, and progression free survival (PFS) and overall survival (OS) using Kaplan Meier and Cox models **Results:** The median age for the cohort was 61 years; 58% pts were male. At diagnosis, 33%, 42%, and 25% pts were International Staging System (ISS) stage I, II, and III; 31% had high risk FISH as per mSMART; median number of prior lines before retreatment was 2 (range 1-12). The index drug was lenalidomide for 45% of pts, bortezomib for 30%, pomalidomide for 11%, and daratumumab for 6% pts. For all pts, the overall response rate (ORR) was 85% (28% ≥VGPR), the median PFS was 11 months (95% CI: 9-13), and the median OS was 53 months (95% CI: 46-66) with retreatment. Of the total 315, 163 (52%) pts were retreated with the index refractory drug in the immediate next line of therapy, and 152 (48%) were retreated with at least 1 intervening line between initial regimen and retreatment. After adjusting for age, ISS stage, high risk FISH, and number of prior lines; pts retreated after 1 or more index drug-free lines had a numerically better PFS (HR=0.7, 95% CI: 0.6-1.1) and OS (HR=0.7, 95% CI: 0.4-1.0) compared to pts retreated in the very next line. After adjusting for above parameters in the subgroup of pts treated after a gap (n=152), pts in quartile (Q) 4 of time gap between last dose of initial regimen and start of retreatment (>34 months) had a better retreatment PFS (HR=0.6, 95% CI: 0.3-1.1) and OS (HR=0.4, 95% CI: 0.2-0.9) as compared to pts in Q1 (< 8 months gap). HRs (95% CI) for Q2 and Q3 were 1.3 (0.7-2.5) and 1.3 (0.7-2.3) for PFS; and 0.9 (0.5-2.0) and 0.8 (0.4-1.7) for OS. **Conclusions:** Retreatment with previously refractory MM drugs might be a viable option, demonstrating an 85% ORR and a 28% ≥VGPR rate in our cohort. Pts retreated with at least 1 intervening line and longer gaps between initial regimen and retreatment had better outcomes than pts retreated in the immediate next line and with shorter index drug-free durations, respectively. These finding highlight the complexity of using refractoriness definitions in defining patient populations for clinical trials.

Introduction: Lenalidomide (LEN) and anti-CD38 monoclonal antibody (mAb)-based regimens are increasingly being incorporated early in the treatment of multiple myeloma (MM). With the evolving MM treatment landscape, understanding real-world treatment patterns and clinical outcomes in patients previously treated with LEN and an anti-CD38 mAb can help in assessing unmet needs. **Methods:** PREAMBLE is a prospective, observational registry that enrolled MM patients in the US, Canada and Europe between 2012

and 2020. Patients eligible for this study were previously treated with LEN and an anti-CD38 mAb in the same or different lines of therapy (LOTs) and initiated a subsequent LOT (index date=date of subsequent LOT initiation). Demographics, clinical characteristics, treatment history, and index treatment regimens were summarized descriptively. Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier method in the overall population and across subgroups defined by region (United States [US] vs ex-US), index LOT (2-4L vs 5L+), age (< 75 vs ≥75 years), and refractory status [refractory to both LEN and an anti-CD38 mAb vs not, triple-class refractory (TCR) vs not]. **Results:** Of 215 eligible patients, most were male (55.8%) and from the US (52.1%), and the median age was 69 years (range 45–92 years). Median time from MM diagnosis to index date was 3.8 years (range 0.3–29.3 years). Median number of prior treatment lines was 3 (range 1–12). Over half (50.7%) of all patients had undergone stem cell transplantation prior to the index date. All patients had previously received daratumumab; 95.8% of patients were also exposed to a proteasome inhibitor, the majority of whom had received bortezomib (95.1%). 80.9% of patients were refractory to LEN and an anti-CD38 mAb and more than half (69.3%) were TCR. Patients' index regimens included approximately 70 different treatment combinations, with carfilzomib ± dexamethasone (Kd; 13.0%), daratumumab/pomalidomide ± dexamethasone (DPd; 7.9%), and pomalidomide ± dexamethasone (Pd; 6.5%) being the most common. The median PFS in the cohort was 5.2 months (95% confidence interval [CI] 3.7–6.7 months) and the median OS was 16.2 months (95% CI 10.3–not reached [NR] months). Some subgroups had numerically worse survival outcomes (ex-US, later LOTs, ≥75 years, refractory to both LEN and an anti-CD38 mAb, and TCR), but only patients who were TCR had significantly shorter OS than those who were not (16.0 months, 95% CI 12.3–21.2 months vs 31.2 months, 95% CI 25.6–NR months). **Conclusions:** Data from this analysis show that after exposure to LEN and an anti-CD38 mAb, MM patients have poor survival outcomes and no clear standard of care. This analysis highlights the need for more effective treatment options for this patient population.

A phase 1b study of isatuximab and bendamustine for triple-class refractory multiple myeloma

Scott Goldsmith[1], Michael Slade[2], Mark Fiala[2], Melinda Harding[2], Zachary Crees[2], Mark Schroeder[2], Keith Stockerl-Goldstein[2], Ravi Vij[2]

[1]City Of Hope National Medical Center, Duarte, CA, USA; [2]Washington University School of Medicine in St. Louis

Introduction: Triple-class refractory MM is associated with poor outcomes. Bendamustine (Benda) has is an active cytotoxic chemotherapy regimen for MM that is well-tolerated with outpatient administration. Isatuximab (Isa) induces caspase-dependent cytotoxicity similar to rituximab. We hypothesized that Isa may synergize with Benda in patients with triple-class refractory disease. **Methods:** We conducted a single-center, phase 1b dose-escalation study to assess the safety, tolerability, and RP2D/MTD of Benda in combination with Isa in patient with triple-class refractory multiple myeloma, defined as treatment with proteasome inhibitor, an immunomodulatory drug, and daratumumab in combination or as single-agents and progression within 60 days of last dose. The study was approved by the local IRB and registered with clinicaltrials.gov (NCT04083898). Patients were enrolled according to a 3+3 dose-escalation design. Isa was administered as 10 mg/kg IV on days 1, 8, 15, and 22 of cycle 1, and days 1 and 15 thereafter. Benda dose levels included: 50, 75, and 100 mg/m^2 administered on days 1 and 2 of each cycle. Patients received methylprednisolone with each dose of Isa, and prednisone on days 2-4. After approval of standard-of-care CAR T therapy, patients were only enrolled if they had progressed after or were considered ineligible for CAR T. Adverse events were grade by CTCAE v 5.0. DLTs definitions adhered to standards for MM clinical trials. **Results:** 15 patients were treated; 3 at 50 Benda, and 6 each at dose 75 and 100. The median age was 71 (56-85) and 10 were male. 8 had high-risk cytogenetics and 9 had extramedullary disease. The median prior lines of MM treatment was 3 (range 2-9) and 60% had underwent ASCT. The median time post-daratumumab was 40 weeks (range 6-168). Cytopenias were common but rarely required intervention. There was only 1 DLT, at 50 benda (G3 thrombocytopenia with bleeding). 7 patients had infectious complications. The median number of cycles administered was 2 (range 1-13); at the time of abstract 2 patients are receiving treatment, both with bulky EMD and objective responses. There was 1 CR, 1 VGPR, 1 PR, and 9 SD. **Conclusions:** Isa + Benda is a safe combination and the MTD was not reached. RP2D is 100mg/m^2 of Benda on days 1 and 2 with conventional Isa dosing. Despite advanced disease with daratumumab-refractoriness, patients had notable disease control, including objective responses at the RP2D in patients with bulky EMD, a difficult subgroup. Unlike other cytoreductive chemotherapy for MM, this regimen allows for outpatient administration. Bendamustine may affect engineering and efficacy of cellular therapies, and is generally avoided pre-leukapheresis. However, Isa-Benda may serve as a reasonable bridging therapy that allows for disease control while reducing risk of severe cytopenias. Recent experience with Benda as a lymphodepleting agent has suggested comparable outcomes. Consequently, Isa-Benda as a novel MM lymphodepleting combination may warrant prospective study.

and 2020. Patients eligible for this study were previously treated with LEN and an anti-CD38 mAb in the same or different lines of therapy (LOTs) and initiated a subsequent LOT (index date=date of subsequent LOT initiation). Demographics, clinical characteristics, treatment history, and index treatment regimens were summarized descriptively. Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier method in the overall population and across subgroups defined by region (United States [US] vs ex-US), index LOT (2-4L vs 5L+), age (< 75 vs ≥75 years), and refractory status [refractory to both LEN and an anti-CD38 mAb vs not, triple-class refractory (TCR) vs not]. **Results:** Of 215 eligible patients, most were male (55.8%) and from the US (52.1%), and the median age was 69 years (range 45–92 years). Median time from MM diagnosis to index date was 3.8 years (range 0.3–29.3 years). Median number of prior treatment lines was 3 (range 1–12). Over half (50.7%) of all patients had undergone stem cell transplantation prior to the index date. All patients had previously received daratumumab; 95.8% of patients were also exposed to a proteasome inhibitor, the majority of whom had received bortezomib (95.1%). 80.9% of patients were refractory to LEN and an anti-CD38 mAb and more than half (69.3%) were TCR. Patients' index regimens included approximately 70 different treatment combinations, with carfilzomib ± dexamethasone (Kd; 13.0%), daratumumab/pomalidomide ± dexamethasone (DPd; 7.9%), and pomalidomide ± dexamethasone (Pd; 6.5%) being the most common. The median PFS in the cohort was 5.2 months (95% confidence interval [CI] 3.7–6.7 months) and the median OS was 16.2 months (95% CI 10.3–not reached [NR] months). Some subgroups had numerically worse survival outcomes (ex-US, later LOTs, ≥75 years, refractory to both LEN and an anti-CD38 mAb, and TCR), but only patients who were TCR had significantly shorter OS than those who were not (16.0 months, 95% CI 12.3–21.2 months vs 31.2 months, 95% CI 25.6–NR months). **Conclusions:** Data from this analysis show that after exposure to LEN and an anti-CD38 mAb, MM patients have poor survival outcomes and no clear standard of care. This analysis highlights the need for more effective treatment options for this patient population.

A phase 1b study of isatuximab and bendamustine for triple-class refractory multiple myeloma

Scott Goldsmith[1], Michael Slade[2], Mark Fiala[2], Melinda Harding[2], Zachary Crees[2], Mark Schroeder[2], Keith Stockerl-Goldstein[2], Ravi Vij[2]

[1]City Of Hope National Medical Center, Duarte, CA, USA; [2]Washington University School of Medicine in St. Louis

Introduction: Triple-class refractory MM is associated with poor outcomes. Bendamustine (Benda) has is an active cytotoxic chemotherapy regimen for MM that is well-tolerated with outpatient administration. Isatuximab (Isa) induces caspase-dependent cytotoxicity similar to rituximab. We hypothesized that Isa may synergize with Benda in patients with triple-class refractory disease. **Methods:** We conducted a single-center, phase 1b dose-escalation study to assess the safety, tolerability, and RP2D/MTD of Benda in combination with Isa in patient with triple-class refractory multiple myeloma, defined as treatment with proteasome inhibitor, an immunomodulatory drug, and daratumumab in combination or as single-agents and progression within 60 days of last dose. The study was approved by the local IRB and registered with clinicaltrials.gov (NCT04083898). Patients were enrolled according to a 3+3 dose-escalation design. Isa was administered as 10 mg/kg IV on days 1, 8, 15, and 22 of cycle 1, and days 1 and 15 thereafter. Benda dose levels included: 50, 75, and 100 mg/m^2 administered on days 1 and 2 of each cycle. Patients received methylprednisolone with each dose of Isa, and prednisone on days 2-4. After approval of standard-of-care CAR T therapy, patients were only enrolled if they had progressed after or were considered ineligible for CAR T. Adverse events were grade by CTCAE v 5.0. DLTs definitions adhered to standards for MM clinical trials. **Results:** 15 patients were treated; 3 at 50 Benda, and 6 each at dose 75 and 100. The median age was 71 (56-85) and 10 were male. 8 had high-risk cytogenetics and 9 had extramedullary disease. The median prior lines of MM treatment was 3 (range 2-9) and 60% had underwent ASCT. The median time post-daratumumab was 40 weeks (range 6-168). Cytopenias were common but rarely required intervention. There was only 1 DLT, at 50 benda (G3 thrombocytopenia with bleeding). 7 patients had infectious complications. The median number of cycles administered was 2 (range 1-13); at the time of abstract 2 patients are receiving treatment, both with bulky EMD and objective responses. There was 1 CR, 1 VGPR, 1 PR, and 9 SD. **Conclusions:** Isa + Benda is a safe combination and the MTD was not reached. RP2D is 100mg/m^2 of Benda on days 1 and 2 with conventional Isa dosing. Despite advanced disease with daratumumab-refractoriness, patients had notable disease control, including objective responses at the RP2D in patients with bulky EMD, a difficult subgroup. Unlike other cytoreductive chemotherapy for MM, this regimen allows for outpatient administration. Bendamustine may affect engineering and efficacy of cellular therapies, and is generally avoided pre-leukapheresis. However, Isa-Benda may serve as a reasonable bridging therapy that allows for disease control while reducing risk of severe cytopenias. Recent experience with Benda as a lymphodepleting agent has suggested comparable outcomes. Consequently, Isa-Benda as a novel MM lymphodepleting combination may warrant prospective study.

Introduction: MEZI is a novel oral cereblon E3 ligase modulator (CELMoD™) with enhanced antimyeloma effects compared with immunomodulatory drugs (IMiDs®). Preclinically, MEZI alone shows potent tumoricidal activity against MM cells and may hold potential as a monotherapy (e.g. where corticosteroids are not desired or indicated). Here we report results from the dose-escalation cohort of the CC-92480-MM-001 trial (NCT03374085) evaluating MEZI monotherapy in patients (pts) with RRMM. **Methods:** Eligible pts had RRMM; ≥3 prior lines of therapy, including ≥2 consecutive cycles of lenalidomide, pomalidomide, a proteasome inhibitor (PI), a glucocorticoid, and an anti-CD38 monoclonal antibody; and disease progression on or within 60 days of last myeloma therapy. MEZI was started at 0.6mg, with possible escalation to 0.8 and 1.0mg, on days 1–21 of each 28-day cycle. De-escalation to 0.4mg was allowed if 0.6mg was not tolerated. Granulocyte-colony stimulating factor was prohibited during the dose-limiting toxicity (DLT) evaluation period (cycle 1). The primary objectives were safety, pharmacokinetics/pharmacodynamics (PD), and determination of the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D). Efficacy was an exploratory objective. **Results:** As of March 22, 2023, 17 pts received MEZI (12 at 0.6mg, 5 at 0.4mg). Median age was 69 (50–76) years. Median number of prior therapies was 5 (3–10), including stem cell transplantation (70.6%); 14 (82.4%) pts were triple-class refractory. Median follow-up was 4.7 (0.4–12.0) months, median number of cycles received was 4 (1–12), and 4 (23.5%) pts were on treatment at data cutoff. Treatment discontinuation was mostly due to progressive disease (52.9%). Grade (Gr) 3–4 treatment-emergent adverse events (TEAEs) occurred in 15 (88.2%) pts. The most frequent hematologic Gr 3–4 TEAEs were neutropenia (76.5%), anemia (41.2%), and leukopenia (29.4%). Gr 3–4 infections were reported in 2/17 pts; rates of other non-hematologic Gr 3–4 TEAEs were low. Twelve (70.6%) and 3 (17.6%) pts had MEZI dose interruptions and reductions due to TEAEs, respectively. No pts discontinued MEZI due to TEAEs. Of the 13 evaluable pts, 1 had a DLT (persistent Gr 4 neutropenia). To date, the MTD/RP2D has not been reached. Overall response rate (ORR) at 0.6mg was 50.0% (6/12) with 1 complete response, 1 very good partial response, and 4 partial responses. Duration of response was immature. There were no responses (0/5) at 0.4mg. MEZI monotherapy was pharmacodynamically active at both 0.4 and 0.6mg doses, promoting target substrate degradation, T-cell proliferation, and reductions in peripheral B cells. **Conclusions:** In pts with heavily pretreated RRMM, MEZI monotherapy at the 0.6mg dose demonstrated a low incidence of severe non-hematologic toxicities with manageable cytopenias, and efficacy consistent with that of MEZI+DEX. Its preliminary safety, efficacy, and PD profile support further development as a corticosteroid-sparing approach in MM.

Pre-clinical characterization of SAR442257, a CD38xCD28xCD3 trispecific T-cell engager in relapsed/refractory multiple myeloma

Anna Grab[1], Peter Kim[2], Kamlesh Bisht[2], Hongfang Wang[2], Halgi Vandevelde[2], Lukas John[3,4], Debarati Shome[5], Irene Sarka[5], Niels Weinhold[3,4], Marc Raab[3]

[1]DKFZ; [2]Sanofi; [3]Department of Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany; [4]Clinical Cooperation Unit Molecular Hematology/Oncology, German Cancer Research Center (DKFZ), Heidelberg, Germany; [5]Lumicks

Introduction: Despite new treatment approaches, most patients with multiple myeloma (MM) develop relapsed/refractory disease (RRMM). CD38-targeting immunomodulators are becoming the standard of care in RRMM. Here we are investigating the first time SAR442257, an anti-CD38/CD3xCD28 trispecific antibody for RRMM. This antibody targets CD38-on MM cells and has a cross-over dual variable (CODV), anti-CD3xCD28 arm that can co-engage and co-stimulate CD3 and CD28 on T-cells, We therefore investigated i) the CD38/CD28-target expression of 100 NDMM and 40 RRMM patients, ii) the enhancement of avidity interaction between MM and T-cell, and iii) the mode of action as well as predictive biomarkers for drug efficiency in 40 RRMM patients (cohort 1: Daratumumab-relapse, 2: Bite-relapse, 3: ELO/POM-relapse). **Methods:** i) We determined the CD28/CD38 expression with FACS and ii) measured cell interaction force between T-cells and MM cells mediated by SAR442257 using a microfluidic approach. iii) The composition of RRMM bone marrow microenvironment was characterized one month after last therapy. For functional assays, CD138+ MM cells and CD3+ T-cellss were isolated from bone marrow of 40 RRMM patients. Dose dependent TC activation, cytokine release and MM cell lysis were measured with FACS. **Results:** The T cell cytotoxicity mediated by SAR442257 is influenced by the binding avidity, primarily depending on target antigen expression. Significantly more RRMM patients (86%) than NDMM patients (14%) expressed CD28, and cell avidity for multi-specific engagers ranked according to target expression (MFI CD38: 380-64000; MFI CD28: 70-1400), reaching more than 50% T-cell-to-MM cell-binding within the first 7min of interaction time. Functional assays showed RRMM patients with Daratumumab-, BiTE- or ELO/POM-treatment could independently be grouped in 2 drug-efficiency-cohorts at 1nM SAR442257: the highly responsive cohort was characterized by complete lysis of MM cells, 80% of autologous T-cell-activation, and patients with Daratumumab-relapse had additionally a factor of 20 lower TGF-B levels. SAR442257 mediated significantly higher MM cell killing compared to bi-specific functional-knockout controls for

Teclistamab is safe and effective in relapse refractory multiple myeloma patients with end stage renal disease: a case series

Patrick Hagen[1]

[1]*Loyola University Chicago*

Introduction: Targeting B-cell maturation antigen (BCMA) has changed treatment approaches in relapsed refractory myeloma (RRMM). Teclistamab is a bi-specific antibody that targets CD3 expressed on T cells and BCMA expressed on myeloma cells. Recently FDA approved based on the MajesTEC-1 trial which excluded patients with a CrCl < 40 mL/min, there is a need to better understand safety and efficacy of RRMM with chronic kidney disease (CKD) seen in up to 50% of RRMM patients as well as those with end stage renal disease (ESRD). Other therapies have been shown to be safe and effective in ESRD patients but there are no reports of teclistamab in this patient population. **Methods:** This was a retrospective study evaluating patients with RRMM with ESRD treated with teclistimab since FDA approval at our institution. **Results:** We report here our experience with two RRMM patients with ESRD who received Teclistamab. The first patient was a 63 year old male with IgG-Lambda MM and R-ISS stage II disease at diagnosis. Prior to treatment, his lambda light chain was 4547.5 mg/L and an IgG 1930 mg/dL with the following high risk features: 8 prior lines of therapy including belantamab; high risk genomics (loss of TP53, amplification 1q, 13q deletion); extramedullary disease. The second patient was a 55 year old male with kappa light chain MM and R-ISS stage II disease at diagnosis. Prior to treatment, his kappa light chain was 1379.6 mg/L with the following high risk features: 8 prior lines of therapy; early progression following transplantation; high risk genomics with amplification of 1q; cirrhosis. Both patients received Teclistimab in standard step up followed by weekly dosing as per package insert immediately following hemodialysis (HD). Adverse events were similar to that reported on the MajesTEC-1 trial with only 1 grade 1 CRS event and both were promptly discharged to continue outpatient treatment without further CRS or neurotoxicity. They both achieved a prompt very good partial response with ongoing disease assessments planned. Importantly, no unexpected adverse events were noted. **Conclusions:** Severe manufacturing shortages of BCMA directed CAR-T therapy (idecel and ciltacel) are daunting with no clear solution in sight. Thus an efficacious bispecific antibody targeting BCMA is sorely needed. Cytopenias and CKD/ESRD would have made both of our patients above ineligible for the MajesTEC-1 trial. Based on the clinical trial data, pharmacodynamics, pharmacokinetics, and experience with other bispecific antibodies, we elected to dose teclistamab in these ESRD patients immediately following HD. Teclistamab can be safely given to high risk RRMM patients with ESRD without unexpected adverse events and responses on par with the MajesTEC-1 trial. Although this preliminary report is promising, further research is warranted and with several other bispecific antibodies showing promising responses in RRMM, our experience should guide further treatments in this challenging patient population.

An innovative interactive case-based online education tool significantly increases knowledge and competence of clinicians managing triple-class refractory multiple myeloma

Victoria Harvey-Jones[1], *Sanneke Koekkoek*[1], *Yelena Parada*[1], *María-Victoria Mateos*[2]

[1]*WebMD/Medscape Oncology Global;* [2]*University Hospital of Salamanca/IBSAL/CIC/CIBERONC, Salamanca, Spain*

Introduction: With BCMA-targeted therapies available for multiple myeloma (MM), such as for triple-class refractory disease, it is important that physicians are knowledgeable and competent in how to use these agents. This study aimed to determine whether online continuing medical education could improve the knowledge, competence, and confidence of hematologists/oncologists (hem/oncs) in managing patients with triple-class refractory MM who are candidates for BCMA-targeted therapy, using a case-based approach. **Methods:** Hem/oncs participated in a 16-minute segmented online multi-media activity consisting of videos portraying realistic physician–patient interactions followed by expert commentaries. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge/competence, and 1 question rated on a Likert-type scale assessed confidence. A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating, and a McNemar's test was conducted at the question or learning objective level (5% significance level, P <.05). Cohen's d with correction for paired samples estimated the effect size of the education on number of correct responses (<.20 modest, .20-.49 small, .59-.79 moderate, ≥.80 large). Data were collected from 01/04/22 to 16/12/22. **Results:** Overall, significant improvements in hem/onc knowledge and competence were seen after participation in the education (average correct response rate: 57% pre-assessment vs 73% post-assessment; P<.01, Cohen's d = 0.46, N=53). 180% more hem/oncs answered all questions correctly after the education (15% pre, 42% post). Specifically, there were significant improvements in knowledge regarding the prognosis of patients with triple-class refractory MM (60% pre-assessment vs 79% post-assessment; P< 0.05), and competence related to selecting the appropriate treatment based on disease-related factors for patients with triple-class refractory disease (34% pre-assessment vs 64% post-assessment; P< 0.01). 42% had a measurable increase in confidence (P< 0.001), resulting in 25% who were mostly or very confident in managing patients with relapsed/refractory MM who are eligible for BCMA-targeted therapy (11% pre-education). Finally, 94% (N=69) reported the education will improve their performance and 91% that it would improve patient outcomes. **Conclusions:** This study demonstrates the ability of innovative

all relapse cohorts, which correlated with enhanced T-cell activation and degranulation (Pearson´s r=0.7). **Conclusions:** SAR442257 has increased binding capacity for RRMM due to CD38 and CD28 targets and demonstrated activity on RRMM cells as reasonable alternative for future RRMM therapy approach.

Teclistamab is safe and effective in relapse refractory multiple myeloma patients with end stage renal disease: a case series

Patrick Hagen[1]

[1]*Loyola University Chicago*

Introduction: Targeting B-cell maturation antigen (BCMA) has changed treatment approaches in relapsed refractory myeloma (RRMM). Teclistamab is a bi-specific antibody that targets CD3 expressed on T cells and BCMA expressed on myeloma cells. Recently FDA approved based on the MajesTEC-1 trial which excluded patients with a CrCl < 40 mL/min, there is a need to better understand safety and efficacy of RRMM with chronic kidney disease (CKD) seen in up to 50% of RRMM patients as well as those with end stage renal disease (ESRD). Other therapies have been shown to be safe and effective in ESRD patients but there are no reports of teclistamab in this patient population. **Methods:** This was a retrospective study evaluating patients with RRMM with ESRD treated with teclistimab since FDA approval at our institution. **Results:** We report here our experience with two RRMM patients with ESRD who received Teclistamab. The first patient was a 63 year old male with IgG-Lambda MM and R-ISS stage II disease at diagnosis. Prior to treatment, his lambda light chain was 4547.5 mg/L and an IgG 1930 mg/dL with the following high risk features: 8 prior lines of therapy including belantamab; high risk genomics (loss of TP53, amplification 1q, 13q deletion); extramedullary disease. The second patient was a 55 year old male with kappa light chain MM and R-ISS stage II disease at diagnosis. Prior to treatment, his kappa light chain was 1379.6 mg/L with the following high risk features: 8 prior lines of therapy; early progression following transplantation; high risk genomics with amplification of 1q; cirrhosis. Both patients received Teclistimab in standard step up followed by weekly dosing as per package insert immediately following hemodialysis (HD). Adverse events were similar to that reported on the MajesTEC-1 trial with only 1 grade 1 CRS event and both were promptly discharged to continue outpatient treatment without further CRS or neurotoxicity. They both achieved a prompt very good partial response with ongoing disease assessments planned. Importantly, no unexpected adverse events were noted. **Conclusions:** Severe manufacturing shortages of BCMA directed CAR-T therapy (idecel and ciltacel) are daunting with no clear solution in sight. Thus an efficacious bispecific antibody targeting BCMA is sorely needed. Cytopenias and CKD/ESRD would have made both of our patients above ineligible for the MajesTEC-1 trial. Based on the clinical trial data, pharmacodynamics, pharmacokinetics, and experience with other bispecific antibodies, we elected to dose teclistamab in these ESRD patients immediately following HD. Teclistamab can be safely given to high risk RRMM patients with ESRD without unexpected adverse events and responses on par with the MajesTEC-1 trial. Although this preliminary report is promising, further research is warranted and with several other bispecific antibodies showing promising responses in RRMM, our experience should guide further treatments in this challenging patient population.

Effectiveness of online education in improving knowledge, competence and confidence of physicians in the management of multiple myeloma

Victoria Harvey-Jones[1], Sanneke Koekkoek[1], Jacob Cohen[1]

[1]WebMD/Medscape Oncology Global

Introduction: The treatment landscape for multiple myeloma (MM) has evolved with newly approved therapies, as well as novel agents in clinical development with emerging data. As a result, it is crucial that physicians are knowledgeable and competent in how to use emerging therapies and understand how treatment may continue to evolve with novel approaches. The aim of this study was to determine whether online continuing medical education (CME) could improve the knowledge, competence and confidence of hematologist/oncologists (hem/oncs) regarding foundational and clinical aspects of MM therapies. **Methods:** Seventeen online educational programmes in multiple delivery formats were launched for hem/oncs outside the USA from 2020 to 2023. Educational effect was assessed for each activity using a repeated-pair design with pre-/post-assessment. For each activity, 3 multiple choice questions (Qs) assessed knowledge/competence, and 1Q rated on a Likert-type scale assessed confidence. A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating, and a McNemar's test was conducted at the Q or learning objective level (5% significance level, P <.05). Data were subsequently combined and analyzed to provide a summative overview of the effect of the education across the combined knowledge-, competence- and confidence-based Qs from the seventeen programs. **Results:** Overall, 1,268 hem/oncs completed pre- and post-activity Qs. Across the seventeen activities, there was a significant change in knowledge/competence after CME (P <.001, 28% relative change [RC]). 91% of hem/oncs either improved or reinforced their knowledge/competence, with 46% demonstrating an improvement. The summative overview showed that hem/oncs had significant improvements in knowledge/competence (P < 0.001) in the following areas related to MM therapies (Ns range from 264 to 861): 1. Mode of action (40% RC). 2. Clinical trial data (21% RC). 3. Treatment selection (30% RC). 4. Practical application (40% RC). In combined self-assessed confidence Qs, hem/oncs had significant improvements (P < 0.001) in confidence (selected 4 or 5 on a scale of 1 to 5, not confident to very confident) in the following areas related to MM therapies (Ns range from 17 to 762): 1. Implications of clinical trial data (80% RC). 2. Treatment selection (107% RC). 3. Practical application (85% RC). Finally, confidence improvements were larger for those who had an improvement/reinforcement of knowledge/competence (unaffected: 2.39 pre-confidence to 2.70 post-confidence rating; improved: 2.31 pre-confidence to 2.97 post-confidence rating; reinforced: 2.49 pre-confidence to 2.97 post-confidence rating). **Conclusions:** These educational activities focused on MM resulted in significant educational impact for hem/oncs. Online CME is valuable in improving knowledge, competence and confidence, as well as identifying areas of future educational need and potentially improving patient outcomes.

P-270

Effectiveness of micro CME at improving clinical knowledge and competence related to BCMA-targeted therapies for relapsed/refractory multiple myeloma

Victoria Harvey-Jones[1], Sarah Bomba[1], Sanneke Koekkoek[1]

[1]WebMD/Medscape Oncology Global

Introduction: With BCMA-targeted therapies available for multiple myeloma (MM), it is important that physicians are knowledgeable and competent in how to use these agents. This study aimed to determine whether online continuing medical education consisting of micro-chapters could improve the knowledge, competence, and confidence of hematologists/oncologists (hem/oncs) in managing patients with relapsed/refractory MM who are candidates for BCMA-targeted therapy. **Methods:** The educational initiative consisted of a collection of five online video-based micro-CME chapters, presented by three respected MM experts, allowing learners to choose the chapters for participation. The education effects were assessed using a repeated pairs pre-assessment/post-assessment study design, where individual participants served as their own control. McNemar's tests (P <.05) determined statistical significance overall in level of mastery of the content (made at least 1 more decision correctly or improved confidence in their correct decisions from pre- to post-education). At the question level, a paired-analysis confidence-based assessment (CBA) measured changes in competence and confidence in learners' pre/post responses to identify learners who are correct and confidence (mastery), correct but not confident (doubt), incorrect or confident (uninformed), and incorrect but confident (misinformed). 1 question was asked per micro chapter. Data were collected from 30/12/22 to 18/04/23. **Results:** Data from 60 hem/oncs who completed the pre/post questions were included in the analysis. Improvements in percentage of correct decisions answered confidently were seen from pre- to post (36% vs 63%, P< 0.001). Overall, 68% hem/oncs improved their knowledge, competence, and confidence. Further results showed: 1. Knowledge regarding the rationale for BCMA-directed therapies for R/R MM: 39% improved (P < 0.001); 225% increase in mastery; 36% decrease uninformed. 2. Knowledge regarding BCMA-directed bispecific antibodies: 43% improved (P < 0.01); 86% increase in mastery; 77% decrease uninformed. 3. Knowledge regarding BCMA-directed CAR T-cell therapies: 54% improved (P < 0.01); 100% increase in mastery; 86% decrease uninformed. 4. Competence related to managing treatment-related adverse events of BCMA-directed antibody conjugates: 45% improved (P=0.058); 23% increase in mastery; 50% decrease uninformed. Knowledge

online, interactive case-based models to transform access to new educational opportunities and improve knowledge and competence of hem/oncs in managing patients with triple class refractory MM. This could lead to improvements in the management of this patient population.

This study aimed to determine whether online continuing medical education consisting of micro-chapters could improve the knowledge, competence, and confidence of hematologists/oncologists (hem/oncs) in managing patients with relapsed/refractory MM who are candidates for BCMA-targeted therapy. **Methods:** The educational initiative consisted of a collection of five online video-based micro-CME chapters, presented by three respected MM experts, allowing learners to choose the chapters for participation. The education effects were assessed using a repeated pairs pre-assessment/post-assessment study design, where individual participants served as their own control. McNemar's tests (P <.05) determined statistical significance overall in level of mastery of the content (made at least 1 more decision correctly or improved confidence in their correct decisions from pre- to post-education). At the question level, a paired-analysis confidence-based assessment (CBA) measured changes in competence and confidence in learners' pre/post responses to identify learners who are correct and confidence (mastery), correct but not confident (doubt), incorrect or confident (uninformed), and incorrect but confident (misinformed). 1 question was asked per micro chapter. Data were collected from 30/12/22 to 18/04/23. **Results:** Data from 60 hem/oncs who completed the pre/post questions were included in the analysis. Improvements in percentage of correct decisions answered confidently were seen from pre- to post (36% vs 63%, P< 0.001). Overall, 68% hem/oncs improved their knowledge, competence, and confidence. Further results showed: 1. Knowledge regarding the rationale for BCMA-directed therapies for R/R MM: 39% improved (P < 0.001); 225% increase in mastery; 36% decrease uninformed. 2. Knowledge regarding BCMA-directed bispecific antibodies: 43% improved (P < 0.01); 86% increase in mastery; 77% decrease uninformed. 3. Knowledge regarding BCMA-directed CAR T-cell therapies: 54% improved (P < 0.01); 100% increase in mastery; 86% decrease uninformed. 4. Competence related to managing treatment-related adverse events of BCMA-directed antibody conjugates: 45% improved (P=0.058); 23% increase in mastery; 50% decrease uninformed. Knowledge

regarding the value of soluble BCMA as a prognostic biomarker: 61% improved (P < 0.01); 69% increase in mastery; 50% decrease uninformed **Conclusions:** This study demonstrates the success of an online CME activity with micro video chapters on improving knowledge, competence, and confidence of hem/oncs related to BCMA-targeted therapies for R/R MM. Additional gaps were identified for future educational targets.

Online CME improves clinical decision-making in the management of patients with relapsed/refractory multiple myeloma

Victoria Harvey-Jones[1], Sanneke Koekkoek[1], Yelena Parada[1]

[1]WebMD/Medscape Oncology Global

Introduction: Managing relapsed/refractory multiple myeloma (R/R MM) is complex for hematologists/oncologists (hem/oncs), with many treatment options available with varying adverse event profiles. We assessed whether an online, virtual patient simulation (VPS) activity could improve the performance of hem/oncs in ordering appropriate tests, treating R/R MM with available therapies, and managing ocular toxicity associated with a MM treatment. **Methods:** This CME-certified VPS consisted of 2 patient cases presented in a platform that allowed physicians to assess the patients and complete open-field entries, choosing from an extensive database of diagnostic and treatment options reflecting the scope and depth of actual practice. After each decision, learners received clinical guidance (CG) based on current evidence and faculty recommendations. Clinical decisions were compared pre- and post-CG using a 2-tailed paired t-test to determine P values (P<.05 is significant). Rationales for clinical decisions were collected in real time. Data were collected between March 2022 and September 2022 and reported here as % relative improvement, P value. **Results:** *Case 1 (n=286 hem/oncs).* 70-yr-old man with a history of MM who has received multiple lines of therapy and requires further treatment. Significant changes observed for: 1. Ordering appropriate tests to evaluate the patient (UIFE, 12%, P<.01; LDH, 10%, P<.01; serum Ig, 16%, P<.01; serum IFE, 10%, P<.01; serum FLC, 13%, P<.01; renal function, 13%, P<.01; peripheral blood smear, 15%, P<.01; LFTs, 10%, P<.01; FBC, 8%, P<.05; BM cytogenetics, 8%, P<.05; 24hr urine protein, 10%, P<.01). 2. Treating patients with R/R MM therapies (selinexor + dexamethasone, 23%, P<.001; idecabtagene vicleucel, 15%, P<.01; zoledronic acid, 45%, P<.001; order follow-up visits, 13%, P<.01). *Case 2 (n=286 hem/oncs).* 76-yr-old man with a history of MM, hypertension, and type 2 diabetes who has completed 3 cycles of belantamab mafodotin (BM) and complained of blurred vision. Significant changes observed for: Management of ocular toxicity associated with therapy for R/R MM (discontinue BM, 31%, P<.001; start preservative-free eye drops, 47%, P<.001; order the following: ophthalmology consult, 45%, P<.001; comprehensive eye exam, 9%, P<.05; compliance with eye drop use, 26%, P<.001; avoid contact lens use, 24%, P<.001; advice regarding operating machinery or driving, 28%, P<.001; patient follow-up, 21%, P<.01) **Conclusions:** These results demonstrate the success of immersive, online VPS education that engages physicians in a practical learning experience in improving their performance in choosing the optimal therapy for patients with R/R MM, as well as managing treatment-related adverse events.

Belantamab mafodotin for relapsed/refractory multiple myeloma: a real-world observational study update

Malin Hultcrantz[1], David Kleinman[2], Ravi Vij[3], Fernando Escalante[4], Michel Delforge[5], Nirali Kotowsky[6], Jacopo Bitetti[7], Natalie Boytsov[6], Leena Camadoo-O'Byrne[8], Lindsey Powers Happ[9], Mujib Rohman[10], Guillaume Germain[11], Mei Sheng Duh[12], Francois Laliberte[13], Malena Mahendran[13], Ana Urosevic[13], Hans Lee[14]

[1]Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Flaum Eye Institute, University of Rochester Medical Center, Rochester, NY, USA; [3]Division of Oncology, Washington University School of Medicine, St Louis, MO, USA; [4]Hematology Department, University Hospital of Leon, Spain; [5]University of Leuven, Leuven, Belgium; [6]GSK, Upper Providence, PA, USA; [7]GSK, Zug, Switzerland; [8]GSK, Stevenage, UK; [9]GSK, Collegeville, PA, USA; [10]GSK, Windsor, UK; [11]Groupe d'Analyse, Ltée., Montreal, Quebec, Canada; [12]Analysis Group, Inc., Boston, MA, USA; [13]Groupe d'Analyse, Ltée., Montreal, Quebec, Canada; [14]Department of Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Introduction: Prior retrospective analysis of US patients (pts) with relapsed/refractory multiple myeloma (RRMM) suggested that pts treated with belantamab mafodotin (belamaf), a B-cell maturation antigen-targeting antibody-drug conjugate, experienced similar outcomes to those who received belamaf in the pivotal DREAMM-2 study. This updated analysis aimed to characterize pts, assess occurrence and management of ocular adverse events (AEs), and evaluate belamaf effectiveness in a real-world setting. **Methods:** This retrospective, longitudinal, observational study used data from the US electronic health record-derived Flatiron Health de-identified database (01/01/2011–06/30/2022). Eligible pts had a confirmed MM diagnosis, initiated belamaf after FDA approval (08/05/2020; first administration=index date), were ≥18 years old at index, and had chart abstraction data for ocular AEs and treatment effectiveness. Data on ocular AEs were reported separately for all pts and pts with ≥4 months of follow-up to allow sufficient evaluation of the incidence of ocular AEs and their mitigations. Tumor response was assessed in all pts, along with Kaplan-Meier estimates of duration of response (DoR), overall survival (OS), and progression-free survival (PFS). **Results:** Of the 184 pts included in the study, mean age was 68.7 years; 64% were White and 47% were female. Eastern Cooperative Oncology Group (ECOG) status was ≥2 in 28% pts, 62% had received ≥5 prior lines of therapy, and 82% were triple-class refractory. Median (IQR) follow-up was 4.1 (1.9–8.5) months. Ocular AEs (≥1) were reported in 50% of all pts (92/184) and 75% of those with ≥4 months of follow-up (70/94):

regarding the value of soluble BCMA as a prognostic biomarker: 61% improved (P < 0.01); 69% increase in mastery; 50% decrease uninformed **Conclusions:** This study demonstrates the success of an online CME activity with micro video chapters on improving knowledge, competence, and confidence of hem/oncs related to BCMA-targeted therapies for R/R MM. Additional gaps were identified for future educational targets.

Introduction: Prior retrospective analysis of US patients (pts) with relapsed/refractory multiple myeloma (RRMM) suggested that pts treated with belantamab mafodotin (belamaf), a B-cell maturation antigen-targeting antibody-drug conjugate, experienced similar outcomes to those who received belamaf in the pivotal DREAMM-2 study. This updated analysis aimed to characterize pts, assess occurrence and management of ocular adverse events (AEs), and evaluate belamaf effectiveness in a real-world setting. **Methods:** This retrospective, longitudinal, observational study used data from the US electronic health record-derived Flatiron Health de-identified database (01/01/2011–06/30/2022). Eligible pts had a confirmed MM diagnosis, initiated belamaf after FDA approval (08/05/2020; first administration=index date), were ≥18 years old at index, and had chart abstraction data for ocular AEs and treatment effectiveness. Data on ocular AEs were reported separately for all pts and pts with ≥4 months of follow-up to allow sufficient evaluation of the incidence of ocular AEs and their mitigations. Tumor response was assessed in all pts, along with Kaplan-Meier estimates of duration of response (DoR), overall survival (OS), and progression-free survival (PFS). **Results:** Of the 184 pts included in the study, mean age was 68.7 years; 64% were White and 47% were female. Eastern Cooperative Oncology Group (ECOG) status was ≥2 in 28% pts, 62% had received ≥5 prior lines of therapy, and 82% were triple-class refractory. Median (IQR) follow-up was 4.1 (1.9–8.5) months. Ocular AEs (≥1) were reported in 50% of all pts (92/184) and 75% of those with ≥4 months of follow-up (70/94):

the most frequent were keratopathy (83% and 83%), blurred vision (57% and 66%), dry eye (35% and 37%), and keratitis (20% and 23%). Among pts with ≥4 months of follow-up, mean time to first ocular AE was 39 (SD: 34) days. Most ocular AEs were managed by therapy hold (69%; of which 73% restarted belamaf) and/or AE treatment (63%). The median dose hold due to ocular AEs was 43 days (physician-reported keratopathy: mild, 21 days; moderate/severe, 56 days). In all pts, 39 (21%) had a derived tumor response based on serum free light chain levels, (partial response: 74%, very good partial response: 51%). For all pts, the estimated median DoR was 9.1 months, PFS 4.5 months, and OS 7.9 months. The 6-month DoR, PFS and OS rates were 57%, 46%, and 58%, respectively. **Conclusions:** Overall, belamaf was effective in the real-world setting in heavily pre-treated pts with RRMM and limited therapy options. The AE profile was consistent with DREAMM-2. Ocular AEs were manageable and despite their occurrence, a high percentage of pts remained on treatment, suggesting belamaf may fill an unmet need for triple-class refractory pts with RRMM.

Isatuximab monotherapy or combination therapy with dexamethasone in older adult patients with relapsed/refractory multiple myeloma: a single institution experience

Masaki Iino[1], Takahiro Mikawa[1], Shinji Kido[1], Ken Fujimori[1]

[1]Yamanashi Prefectural Central Hospital

Introduction: Isatuximab monotherapy (20 mg/kg div, Isa20) or combination therapy with dexamethasone (Isa20+D) has proven effective and safe in patients with relapsed/refractory multiple myeloma (RRMM). Because of the low incidence of severe adverse events, these treatments have been used for disease control in older adult patients who are intolerant to prior treatment and/or to maintain the efficacy of prior treatment in our hospital. In this study, we retrospectively evaluated the efficacy and safety of Isa20 and Isa20+D in older adult patients. **Methods:** We examined the efficacy and safety of Isa20 and Isa20+D using the medical records of RRMM patients aged ≥ 80 years, who were treated at our hospital between 2021 and 2023. The response was evaluated according to the International Myeloma Working Group Uniform Response Criteria. Median overall survival (OS) and time to next treatment (TTNT) were estimated using the Kaplan–Meier method. Adverse events were evaluated according to the National Cancer Institute Common Toxicity Criteria version 5.0. The study was approved by the ethics committee of Yamanashi Prefectural Central Hospital and was conducted in accordance with the principles of the Declaration of Helsinki. **Results:** Fifteen patients received either Isa20 (n = 3) or Isa20+D (n = 12). The patient characteristics at diagnosis were: a median age of 83 years (range, 80–92), a male to female ratio of 8:7, and International Staging System stages I/II/III = 3:5:7 patients. The median number of prior treatments was three. Five patients had creatinine clearance < 30 mL/min, eight patients had high-risk cytogenetic abnormalities (at least one of t[4;14], t[14;16], del 17p, or 1q21 gain/amplification), and eleven patients had previously received daratumumab. All patients were classed as frail according to the International Myeloma Working Group Frailty Criteria. The reason for choosing Isa20 or Isa20+D treatment was intolerance to previous treatment (because of chronic heart failure, three patients; appetite loss, two patients; cytopenia, two patients; infection, two patients; renal dysfunction, one patient; liver dysfunction, one patient) and the need to maintain a treatment response (four patients). The disease control rate (i.e., stable disease or better) was 80%. After a median follow-up period of 10 months, the median TTNT was 7.5 months. The median OS was not reached. At the time of analysis, eight patients had discontinued treatment. The main reason for treatment discontinuation was disease progression. Regarding adverse events, an infusion reaction was extremely rare and no unexpected adverse events were identified in this study. **Conclusions:** Isa20 and Isa20+D remain useful and feasible treatment options in a real-world setting, even in frail older adult patients with RRMM.

Efficacy and safety of elranatamab in Japanese patients with relapsed/refractory multiple myeloma (RRMM): a pooled analysis from the MagnetisMM studies

Tadao Ishida[1], Hisayuki Yokoyama[2], Kenshi Suzuki[1], Satoshi Ito[3], Yuya Nagai[4], Hiroshi Handa[5], Shigeki Ito[6], Yoichi Kamei[7], Masatoshi Nakamura[7], Andrea Viqueira[8], Jane Liang White[9], Kazumi Take[10], Toyoki Moribe[10], Shinsuke Iida[11]

[1]Japanese Red Cross Medical Center, Tokyo, Japan; [2]Tohoku University Graduate School of Medicine, Sendai, Japan; [3]Yamagata University Hospital, Yamagata, Japan; [4]Kobe City Medical Center General Hospital, Kobe, Japan; [5]Gunma University Graduate School of Medicine, Maebashi, Japan; [6]School of Medicine, Iwate Medical University, Yahaba, Japan; [7]Pfizer R&D Japan GK, Tokyo, Japan; [8]Pfizer SLU, Madrid, Spain; [9]Pfizer Inc, Groton, Connecticut, USA; [10]Pfizer Japan Inc., Tokyo, Japan; [11]Institute of Medical and Pharmaceutical Sciences, Nagoya City University, Japan

Introduction: This was a pooled analysis of Japanese patients (pts) with RRMM enrolled in the MagnetisMM studies MM-2 (NCT04798586) and MM-3 (NCT04649359) that evaluated the efficacy and safety of elranatamab. **Methods:** MagnetisMM-2 was a single-arm, open-label, multicenter, phase 1 study to evaluate elranatamab monotherapy of 1000 µg/kg SC weekly, with a 600 µg/kg SC priming dose, in Japanese pts with RRMM who received ≥3 prior therapies (≥1 proteasome inhibitor (PI), ≥1 immunomodulatory drug (IMiD), and ≥1 anti-CD38 antibody). MagnetisMM-3 is an ongoing open-label, multicenter, non-randomized, phase 2 study in pts with RRMM refractory to ≥1 PI, ≥1 IMiD and ≥1 anti-CD38 antibody, with elranatamab administered SC at a fixed dose of 76 mg weekly. Pts received SC elranatamab in 28-d cycles with step-up doses of 12 mg on C1D1 and 32 mg on C1D4 followed by 76 mg QW beginning C1D8. **Results:** In total, 16 pts (MM-2, n=4; MM-3, n=12) were included, 62.5% were male and median age was 68.5 y (range, 47–83). At baseline, pts had an ECOG PS of 0

the most frequent were keratopathy (83% and 83%), blurred vision (57% and 66%), dry eye (35% and 37%), and keratitis (20% and 23%). Among pts with ≥4 months of follow-up, mean time to first ocular AE was 39 (SD: 34) days. Most ocular AEs were managed by therapy hold (69%; of which 73% restarted belamaf) and/or AE treatment (63%). The median dose hold due to ocular AEs was 43 days (physician-reported keratopathy: mild, 21 days; moderate/severe, 56 days). In all pts, 39 (21%) had a derived tumor response based on serum free light chain levels, (partial response: 74%, very good partial response: 51%). For all pts, the estimated median DoR was 9.1 months, PFS 4.5 months, and OS 7.9 months. The 6-month DoR, PFS and OS rates were 57%, 46%, and 58%, respectively. **Conclusions:** Overall, belamaf was effective in the real-world setting in heavily pre-treated pts with RRMM and limited therapy options. The AE profile was consistent with DREAMM-2. Ocular AEs were manageable and despite their occurrence, a high percentage of pts remained on treatment, suggesting belamaf may fill an unmet need for triple-class refractory pts with RRMM.

Isatuximab monotherapy or combination therapy with dexamethasone in older adult patients with relapsed/refractory multiple myeloma: a single institution experience

Masaki Iino[1], Takahiro Mikawa[1], Shinji Kido[1], Ken Fujimori[1]

[1]Yamanashi Prefectural Central Hospital

Introduction: Isatuximab monotherapy (20 mg/kg div, Isa20) or combination therapy with dexamethasone (Isa20+D) has proven effective and safe in patients with relapsed/refractory multiple myeloma (RRMM). Because of the low incidence of severe adverse events, these treatments have been used for disease control in older adult patients who are intolerant to prior treatment and/or to maintain the efficacy of prior treatment in our hospital. In this study, we retrospectively evaluated the efficacy and safety of Isa20 and Isa20+D in older adult patients. **Methods:** We examined the efficacy and safety of Isa20 and Isa20+D using the medical records of RRMM patients aged ≥ 80 years, who were treated at our hospital between 2021 and 2023. The response was evaluated according to the International Myeloma Working Group Uniform Response Criteria. Median overall survival (OS) and time to next treatment (TTNT) were estimated using the Kaplan–Meier method. Adverse events were evaluated according to the National Cancer Institute Common Toxicity Criteria version 5.0. The study was approved by the ethics committee of Yamanashi Prefectural Central Hospital and was conducted in accordance with the principles of the Declaration of Helsinki. **Results:** Fifteen patients received either Isa20 (n = 3) or Isa20+D (n = 12). The patient characteristics at diagnosis were: a median age of 83 years (range, 80–92), a male to female ratio of 8:7, and International Staging System stages I/II/III = 3:5:7 patients. The median number of prior treatments was three. Five patients had creatinine clearance < 30 mL/min, eight patients had high-risk cytogenetic abnormalities (at least one of t[4;14], t[14;16], del 17p, or 1q21 gain/amplification), and eleven patients had previously received daratumumab. All patients were classed as frail according to the International Myeloma Working Group Frailty Criteria. The reason for choosing Isa20 or Isa20+D treatment was intolerance to previous treatment (because of chronic heart failure, three patients; appetite loss, two patients; cytopenia, two patients; infection, two patients; renal dysfunction, one patient; liver dysfunction, one patient) and the need to maintain a treatment response (four patients). The disease control rate (i.e., stable disease or better) was 80%. After a median follow-up period of 10 months, the median TTNT was 7.5 months. The median OS was not reached. At the time of analysis, eight patients had discontinued treatment. The main reason for treatment discontinuation was disease progression. Regarding adverse events, an infusion reaction was extremely rare and no unexpected adverse events were identified in this study. **Conclusions:** Isa20 and Isa20+D remain useful and feasible treatment options in a real-world setting, even in frail older adult patients with RRMM.

Introduction: This was a pooled analysis of Japanese patients (pts) with RRMM enrolled in the MagnetisMM studies MM-2 (NCT04798586) and MM-3 (NCT04649359) that evaluated the efficacy and safety of elranatamab. **Methods:** MagnetisMM-2 was a single-arm, open-label, multicenter, phase 1 study to evaluate elranatamab monotherapy of 1000 µg/kg SC weekly, with a 600 µg/kg SC priming dose, in Japanese pts with RRMM who received ≥3 prior therapies (≥1 proteasome inhibitor (PI), ≥1 immunomodulatory drug (IMiD), and ≥1 anti-CD38 antibody). MagnetisMM-3 is an ongoing open-label, multicenter, non-randomized, phase 2 study in pts with RRMM refractory to ≥1 PI, ≥1 IMiD and ≥1 anti-CD38 antibody, with elranatamab administered SC at a fixed dose of 76 mg weekly. Pts received SC elranatamab in 28-d cycles with step-up doses of 12 mg on C1D1 and 32 mg on C1D4 followed by 76 mg QW beginning C1D8. **Results:** In total, 16 pts (MM-2, n=4; MM-3, n=12) were included, 62.5% were male and median age was 68.5 y (range, 47–83). At baseline, pts had an ECOG PS of 0

the most frequent were keratopathy (83% and 83%), blurred vision (57% and 66%), dry eye (35% and 37%), and keratitis (20% and 23%). Among pts with ≥4 months of follow-up, mean time to first ocular AE was 39 (SD: 34) days. Most ocular AEs were managed by therapy hold (69%; of which 73% restarted belamaf) and/or AE treatment (63%). The median dose hold due to ocular AEs was 43 days (physician-reported keratopathy: mild, 21 days; moderate/severe, 56 days). In all pts, 39 (21%) had a derived tumor response based on serum free light chain levels, (partial response: 74%, very good partial response: 51%). For all pts, the estimated median DoR was 9.1 months, PFS 4.5 months, and OS 7.9 months. The 6-month DoR, PFS and OS rates were 57%, 46%, and 58%, respectively. **Conclusions:** Overall, belamaf was effective in the real-world setting in heavily pre-treated pts with RRMM and limited therapy options. The AE profile was consistent with DREAMM-2. Ocular AEs were manageable and despite their occurrence, a high percentage of pts remained on treatment, suggesting belamaf may fill an unmet need for triple-class refractory pts with RRMM.

At baseline, pts had an ECOG PS of 0

(50.0%) or 1 (50.0%); 37.5% had high risk cytogenetics; 25.0% had extramedullary disease. Pts received a median of 7.0 (2–11) prior lines of therapy, all pts were triple-class refractory and 8 pts (50.0%) were penta-drug refractory, and 15 pts (93.8%) were refractory to the last line of therapy. After a median follow-up of 11.1 mo (2.4–13.1), 43.8% of pts remained on treatment; the most common reason for permanent treatment discontinuation was progressive disease (37.5%). The objective response rate by investigator was 50.0% (95% CI 24.7–75.3), although not yet mature at the time of analysis; 37.5% and 50.0% achieved complete response or better and very good partial response or better, respectively. Among responders, the median duration of response was not reached (95% CI 9.2, NE) and the probability of maintaining the response at 9 months was 100% (95% CI: 100, 100). Dose reduction or interruption due to AEs occurred in 87.5% of pts and 1 pt permanently discontinued due to AEs (neutropenia, thrombocytopenia). 15 (93.8%) of pts reported G3/4 AEs. The most common TEAEs (≥50% of pts) were neutropenia (13 (81.3%) [G3/4, 13 (81.3%)]) and CRS (11 (68.8%) [G3/4, 1 (6.3%)]). No pt had ICANS. Overall, 5 (31.3%) pts died; 4 (25%) due to disease progression, 1 (6.3%) unknown. **Conclusions:** Deep and durable responses to elranatamab monotherapy were observed in Japanese pts with heavily pre-treated refractory MM. The safety profile was manageable and no new safety signals were identified. These results support the continued development of elranatamab for the treatment of RRMM in Japanese pts.

Introduction: Heavily pretreated patients with relapsed/refractory multiple myeloma (RRMM) treated with standard of care therapy have median overall survival (OS) of ~9-12 months. In the single-arm, phase 1b/2 CARTITUDE-1 study (NCT03548207), patients received a single infusion of ciltacabtagene autoleucel (cilta-cel), a chimeric antigen receptor-T cell therapy targeting B-cell maturation antigen. At the final protocol-specified analysis (27.7-month median follow-up), overall response rate (ORR) was 98%, with 83% stringent complete response; 27-month rates of progression-free survival (PFS) and OS were 55% and 70%, respectively. Here, we report CARTITUDE-1 study close out efficacy and safety results. **Methods:** Informed consent was obtained prior to study entry. Enrolled patients had received ≥3 prior lines of therapy (LOT) or were double refractory to a proteasome inhibitor (PI) and immunomodulatory drug (IMiD); and had received prior PI, IMiD, and anti-CD38 antibody therapy. Primary endpoint was ORR and safety; secondary endpoints included PFS, OS, and minimal residual disease (MRD)-negativity at 10^{-5}. **Results:** 97 patients received cilta-cel (59% male; median age 61 years; median of 6 prior LOT; 42% penta-drug refractory; 88% triple-class refractory; 99% refractory to last LOT). As of October 14, 2022, median follow-up was 33.4 months (range, 1.5–45.2). Median duration of response was 33.9 month (95% CI, 25.5–not estimable). Median PFS was 34.9 months (95% CI, 25.2–NE), with an estimated 47.5% of patients progression free and alive at 36 months. Median OS was not reached, with an estimated 62.9% survival at 36 months. Of 49 MRD-evaluable patients, 26 had MRD-negativity sustained for ≥12 months, of which 20 had sustained MRD-negative complete response (CR) or better. Median PFS was not reached in subgroups with ≥CR and/or sustained MRD negativity. Eighteen patients were MRD-negative with ≥CR at 24-months post infusion. No new neurotoxicity events were reported since the 27.7-month median follow-up. Six new cases of second primary malignancy were reported, including 2 cases of basal cell carcinoma and 1 case each of myelodysplastic syndrome, B-cell lymphoma, melanoma, and prostate cancer. Five additional deaths occurred (progressive disease [PD], n=3; pneumonia and sepsis, n=1 each [both unrelated to cilta-cel]), for a total of 35 deaths (PD, n=17; unrelated to cilta-cel, n=12; related, n=6). **Conclusions:** Longer median PFS was observed after a single infusion of cilta-cel than any previously reported therapy in heavily pretreated patients with RRMM. Achieving CR and/or sustained MRD-negativity was associated with prolonged PFS. Patients continue to be followed for safety and survival in the 15-year CARTINUE long-term study (NCT05201781; MMY4002). Data previously presented at the 2023 American Society of Clinical Oncology (ASCO) Annual Meeting.

Here, we report CARTITUDE-1 study close out efficacy and safety results. **Methods:** Informed consent was obtained prior to study entry. Enrolled patients had received ≥3 prior lines of therapy (LOT) or were double refractory to a proteasome inhibitor (PI) and immunomodulatory drug (IMiD); and had received prior PI, IMiD, and anti-CD38 antibody therapy. Primary endpoint was ORR and safety; secondary endpoints included PFS, OS, and minimal residual disease (MRD)-negativity at 10^{-5}. **Results:** 97 patients received cilta-cel (59% male; median age 61 years; median of 6 prior LOT; 42% penta-drug refractory; 88% triple-class refractory; 99% refractory to last LOT). As of October 14, 2022, median follow-up was 33.4 months (range, 1.5–45.2). Median duration of response was 33.9 month (95% CI, 25.5–not estimable). Median PFS was 34.9 months (95% CI, 25.2–NE), with an estimated 47.5% of patients progression free and alive at 36 months. Median OS was not reached, with an estimated 62.9% survival at 36 months. Of 49 MRD-evaluable patients, 26 had MRD-negativity sustained for ≥12 months, of which 20 had sustained MRD-negative complete response (CR) or better. Median PFS was not reached in subgroups with ≥CR and/or sustained MRD negativity. Eighteen patients were MRD-negative with ≥CR at 24-months post infusion. No new neurotoxicity events were reported since the 27.7-month median follow-up. Six new cases of second primary malignancy were reported, including 2 cases of basal cell carcinoma and 1 case each of myelodysplastic syndrome, B-cell lymphoma, melanoma, and prostate cancer. Five additional deaths occurred (progressive disease [PD], n=3; pneumonia and sepsis, n=1 each [both unrelated to cilta-cel]), for a total of 35 deaths (PD, n=17; unrelated to cilta-cel, n=12; related, n=6). **Conclusions:** Longer median PFS was observed after a single infusion of cilta-cel than any previously reported therapy in heavily pretreated patients with RRMM. Achieving CR and/or sustained MRD-negativity was associated with prolonged PFS. Patients continue to be followed for safety and survival in the 15-year CARTINUE long-term study (NCT05201781; MMY4002). Data previously presented at the 2023 American Society of Clinical Oncology (ASCO) Annual Meeting.

Healthcare resource utilization and costs among patients with relapsed/refractory multiple myeloma treated with chimeric antigen receptor-T (CAR-T) cell therapy

Sundar Jagannath[1], Akshay Kharat[2], Alex Fu[3,4], Stephen Huo[2], Monal Kohli[5], Shayna Adams[5], Emeka Umeh[5], Miran Foster[5]

[1]Mount Sinai Medical Center, New York, NY, USA; [2]Janssen Pharmaceuticals, Titusville, NJ, USA; [3]Janssen Scientific Affairs, LLC, Titusville NJ, USA; [4]Georgetown University Medical Center, Washington, DC, USA; [5]STATInMED

Introduction: Chimeric antigen receptor-T (CAR-T) therapies have advanced treatment of multiple myeloma (MM); however, healthcare resource utilization (HCRU) and costs are not well characterized for patients with relapsed/refractory MM (RRMM) who receive commercial CAR-T therapy. The study aim was to describe real-world HCRU and costs in patients with RRMM who received commercial CAR-T treatment. **Methods:** This longitudinal, retrospective, observational study identified patients with RRMM treated with commercial CAR-T using the US national all-payer claims database that covers approximately 80% of the nationally insured population. Adults were eligible if they had ≥1 inpatient or outpatient claim with MM diagnosis and ≥1 claim for commercial CAR-T (idecabtagene vicleucel or ciltacabtagene autoleucel) from March 1, 2021, to September 30, 2022, with ≥12 months continuous enrollment before CAR-T infusion and if they were not enrolled in a clinical trial during the study period. All-cause HCRU and costs (in 2022 US $) were evaluated starting from the day of CAR-T infusion up to day 30 and from day 31 to 100 and day 101 to 180 post-infusion. **Results:** Of the 196 patients who received commercial CAR-T therapy, the mean age was 64.2 years, 58.2% were male, 130 (66.3%) received bridging therapy before CAR-T infusion, and 179 (91.3%) received inpatient CAR-T infusion. Including the day of CAR-T infusion up to 30-day follow-up (n=153), mean (standard deviation [SD]) total all-cause cost per patient per month (PPPM) was $586,801 ($250,128) inclusive of CAR-T drug costs and infusion encounter costs (mean [SD], $522,920 [$201,557]). Mean (SD) total cost PPPM from day 31 to 100 (n=94) and day 101 to 180 (n=50) post-infusion was $11,780 ($13,738) and $6,701 ($17,559), respectively. Including CAR-T infusion day to 30-day follow-up, mean (SD) number of inpatient admissions was 1.8 (2.3) PPPM with a mean (SD) length of stay (LOS) of 14.6 (8.1) days PPPM; 5.2% had ≥1 emergency room (ER) visit; and mean (SD) number of outpatient visits PPPM was 9.1 (5.8). From 31 to 100 days post-infusion, mean (SD) number of outpatient visits PPPM was 2.7 (2.5); 8.5% had ≥1 ER visit; and mean (SD) inpatient admissions PPPM was 0.4 (1.1) with a mean (SD) LOS of 1.1 (3.5) days PPPM. From 101 to 180 days post-infusion, mean (SD) number of outpatient visits PPPM was 1.7 (2.8); 2.0% had ≥1 ER visit; and mean (SD) number of inpatient admissions PPPM was 0.1 (0.5) with a mean (SD) LOS of 0.4 (1.1) days PPPM. **Conclusions:** Patients with RRMM who received CAR-T incurred ~$632,000 in all-cause healthcare costs through 180 days post-infusion, inclusive of CAR-T drug costs. HCRU and costs tapered beyond 30 days to 180 days post-infusion.

Introduction: Venetoclax (Ven) plus daratumumab and dexamethasone (VenDd) has demonstrated preliminary antitumor activity in patients (pts) with t(11;14)+ relapsed/refractory multiple myeloma (RRMM; Phase 1/2). Here, we report updated safety and efficacy from this Phase1/2 trial of VenDd at 400 and 800 mg Ven dose levels, versus bortezomib plus Dd (DVd) in pts with t(11;14)+ RRMM. **Methods:** Parts 1 (nonrandomized) and 3 (randomized among 400 mg VenDd, 800 mg VenDd and DVd arms) in this Phase 1/2 multicenter study evaluated VenDd versus DVd in pts with t(11;14)+ RRMM, who had ≥1 prior line of therapy (LOT), including proteasome inhibitor and immunomodulatory drug exposure (NCT03314181). Pts in the investigational arm (VenDd, 28 day [D] cycles [C]) received oral Ven once daily (400 mg or 800 mg) with daratumumab (either 16 mg/kg IV or 1800 mg subcutaneous [C1–2: D1, {D2 if split dosing in C1 for IV daratumumab}, 8, 15, 22; C3–6: D1 and 15; C7+: D1]) and dexamethasone (40 mg weekly; oral/IV); pts in the DVd arm were dosed per label recommendations. Overall response rate (ORR) was defined as ≥partial response per IMWG criteria. Minimal residual disease negativity (MRD–) was assessed in bone marrow using next-generation sequencing. This trial was designed to compare safety and preliminary efficacy of VenDd (at 400 or 800 mg Ven doses) with DVd (control). **Results:** Part 1 enrolled 5 pts (400 mg VenDd) and 19 pts (800 mg VenDd). Part 3 enrolled 21, 10, and 26 pts in the 400 mg VenDd, 800 mg VenDd and DVd arms. As of Mar 10, 2023, 80 total pts were enrolled (Parts 1 and 3 combined); 55 pts received VenDd (11% del17p, 13% 1q21abn; 53% 1 prior LOT, 2% prior anti-CD38 mAb); and 24 received DVd (21% del17p; 38% 1 prior LOT, 4% anti-CD38 mAb). Median (range) follow-up and treatment exposure (months) were longer with VenDd than Dvd (28.2 [1.0–

Pts in the investigational arm (VenDd, 28 day [D] cycles [C]) received oral Ven once daily (400 mg or 800 mg) with daratumumab (either 16 mg/kg IV or 1800 mg subcutaneous [C1–2: D1, {D2 if split dosing in C1 for IV daratumumab}, 8, 15, 22; C3–6: D1 and 15; C7+: D1]) and dexamethasone (40 mg weekly; oral/IV); pts in the DVd arm were dosed per label recommendations. Overall response rate (ORR) was defined as ≥partial response per IMWG criteria. Minimal residual disease negativity (MRD–) was assessed in bone marrow using next-generation sequencing. This trial was designed to compare safety and preliminary efficacy of VenDd (at 400 or 800 mg Ven doses) with DVd (control). **Results:** Part 1 enrolled 5 pts (400 mg VenDd) and 19 pts (800 mg VenDd). Part 3 enrolled 21, 10, and 26 pts in the 400 mg VenDd, 800 mg VenDd and DVd arms. As of Mar 10, 2023, 80 total pts were enrolled (Parts 1 and 3 combined); 55 pts received VenDd (11% del17p, 13% 1q21abn; 53% 1 prior LOT, 2% prior anti-CD38 mAb); and 24 received DVd (21% del17p; 38% 1 prior LOT, 4% anti-CD38 mAb). Median (range) follow-up and treatment exposure (months) were longer with VenDd than Dvd (28.2 [1.0–

55.7] and 23.3 [1.2–56.3] with VenDd vs 16.9 [0.0–34.1] and 9.6 [0.5–33.9] with DVd). The most common AEs (>30%) with DVd were diarrhea, insomnia, and fatigue, and with VenDd were those plus nausea, upper respiratory tract infection, and COVID-19. SAE rates were 51% (VenDd) and 25% (DVd). Discontinuation due to AEs occurred with 6% of pts with VenDd (none with DVd). VenDd achieved 96% ORR, 93% ≥VGPR, 67% ≥CR, 35% MRD– at 10^{-5} and median PFS not reached (95% CI: 35.0–NE). DVd achieved: 65% ORR, 39% ≥VGPR, 19% ≥CR, 8% MRD– at 10^{-5}, and median PFS 15.5 months (7.5–NE). The 33-month PFS rate was 73.4% (95% CI: 56.4–84.6) vs 38.8% (16.3–61.1) for VenDd vs DVd. Of 8 VenDd-treated pts assessed for duration of MRD–, 6 had MRD– >6 months, of whom 2 had MRD– >12 months. No DVd-treated pts had durable MRD– >6 months. **Conclusions:** VenDd produced deep and durable responses, improved outcomes compared with DVd, and had a manageable safety profile in pts with t(11;14)+ RRMM. Data supporting Venetoclax dose selection will be presented.

Estimating the size of patients with relapsed/refractory multiple myeloma treated with 1-3 and 4 or more prior lines of therapy in the United States

Doris Hansen[1], Akshay Kharat[2], Ravi Potluri[3], Sanjog Patidar[3], Stephen Huo[2], Jack Khouri[4]

[1]Moffiitt Cancer Center; [2]Janssen Pharmaceuticals; [3]Putnam Associates; [4]Taussig Cancer Institute, Cleveland Clinic

Introduction: Approximately 35,000 new cases of multiple myeloma (MM) are diagnosed in the United States every year. Multiple therapies are available for the treatment of MM across the proteasome inhibitor (PI), immunomodulatory drug (IMiD), and anti-CD38 antibody classes. However, evidence suggests that the number of patients eligible for treatment declines after exposure to these classes. The objective of this study was to build an MM disease progression model to estimate the size of the MM patient population with a historically high risk of progression stratified by (1) 1-3 prior lines of therapy (LOT) and (2) ≥4 prior LOT in the United States. **Methods:** A disease model was developed starting with the annual incidence of MM and applying different treatment pathways to generate patient buckets based on treatments received in prior LOT. Patients were classified as having 1-3 prior LOT if they received 1-3 prior LOT and were PI- and IMiD-exposed and refractory to lenalidomide in at least 1 prior line. Patients were classified as having ≥4 prior LOT if they received ≥4 prior LOT including a PI, IMiD, and anti-CD38 monoclonal antibody (ie, triple-class exposed). Claims databases representative of the US MM population and public sources including the SEER*Stat epidemiologic database were used to obtain inputs for the model. Overall, the model estimated the number of patients in the US with 1-3 and ≥4 prior LOT by calendar year and stratified by race/ethnicity and payer-type subgroups. **Results:** An estimated 25,096 patients would have had 1-3 prior LOT, and 15,772 would have had ≥4 prior LOT in 2024. In 2026, the population size is an estimated 22,848 patients with 1-3 prior LOT and 9,643 with ≥4 prior LOT. By race/ethnicity subgroups, the estimated population in 1-3 and ≥4 prior LOT combined would include 30,217 White (74%), 8,857 Black (22%), 956 Hispanic (2%), and 838 Asian (2%) patients in 2024 and 24,023 White (74%), 7,041 Black (22%), 760 Hispanic (2%), and 666 Asian (2%) patients in 2026. The estimated population in 1-3 and ≥4 prior LOT combined by payer type would be 28,016 Medicare (69%) and 12,852 commercial (31%) patients in 2024 and would include 22,702 Medicare (70%) and 9,789 commercial (30%) patients in 2026. **Conclusions:** The data from this MM disease progression model indicate that fewer patients are anticipated to move into the 1-3 prior LOT, PI-exposed, and lenalidomide-refractory relapsed/refractory MM (RRMM) and ≥4 prior LOT triple-class exposed RRMM settings in 2026 versus 2024.

55.7] and 23.3 [1.2–56.3] with VenDd vs 16.9 [0.0–34.1] and 9.6 [0.5–33.9] with DVd). The most common AEs (>30%) with DVd were diarrhea, insomnia, and fatigue, and with VenDd were those plus nausea, upper respiratory tract infection, and COVID-19. SAE rates were 51% (VenDd) and 25% (DVd). Discontinuation due to AEs occurred with 6% of pts with VenDd (none with DVd). VenDd achieved 96% ORR, 93% ≥VGPR, 67% ≥CR, 35% MRD– at 10^{-5} and median PFS not reached (95% CI: 35.0–NE). DVd achieved: 65% ORR, 39% ≥VGPR, 19% ≥CR, 8% MRD– at 10^{-5}, and median PFS 15.5 months (7.5–NE). The 33-month PFS rate was 73.4% (95% CI: 56.4–84.6) vs 38.8% (16.3–61.1) for VenDd vs DVd. Of 8 VenDd-treated pts assessed for duration of MRD–, 6 had MRD– >6 months, of whom 2 had MRD– >12 months. No DVd-treated pts had durable MRD– >6 months. **Conclusions:** VenDd produced deep and durable responses, improved outcomes compared with DVd, and had a manageable safety profile in pts with t(11;14)+ RRMM. Data supporting Venetoclax dose selection will be presented.

Estimating the size of patients with relapsed/refractory multiple myeloma treated with 1-3 and 4 or more prior lines of therapy in the United States

Doris Hansen[1], Akshay Kharat[2], Ravi Potluri[3], Sanjog Patidar[3], Stephen Huo[2], Jack Khouri[4]

[1]Moffiitt Cancer Center; [2]Janssen Pharmaceuticals; [3]Putnam Associates; [4]Taussig Cancer Institute, Cleveland Clinic

Introduction: Approximately 35,000 new cases of multiple myeloma (MM) are diagnosed in the United States every year. Multiple therapies are available for the treatment of MM across the proteasome inhibitor (PI), immunomodulatory drug (IMiD), and anti-CD38 antibody classes. However, evidence suggests that the number of patients eligible for treatment declines after exposure to these classes. The objective of this study was to build an MM disease progression model to estimate the size of the MM patient population with a historically high risk of progression stratified by (1) 1-3 prior lines of therapy (LOT) and (2) ≥4 prior LOT in the United States. **Methods:** A disease model was developed starting with the annual incidence of MM and applying different treatment pathways to generate patient buckets based on treatments received in prior LOT. Patients were classified as having 1-3 prior LOT if they received 1-3 prior LOT and were PI- and IMiD-exposed and refractory to lenalidomide in at least 1 prior line. Patients were classified as having ≥4 prior LOT if they received ≥4 prior LOT including a PI, IMiD, and anti-CD38 monoclonal antibody (ie, triple-class exposed). Claims databases representative of the US MM population and public sources including the SEER*Stat epidemiologic database were used to obtain inputs for the model. Overall, the model estimated the number of patients in the US with 1-3 and ≥4 prior LOT by calendar year and stratified by race/ethnicity and payer-type subgroups. **Results:** An estimated 25,096 patients would have had 1-3 prior LOT, and 15,772 would have had ≥4 prior LOT in 2024. In 2026, the population size is an estimated 22,848 patients with 1-3 prior LOT and 9,643 with ≥4 prior LOT. By race/ethnicity subgroups, the estimated population in 1-3 and ≥4 prior LOT combined would include 30,217 White (74%), 8,857 Black (22%), 956 Hispanic (2%), and 838 Asian (2%) patients in 2024 and 24,023 White (74%), 7,041 Black (22%), 760 Hispanic (2%), and 666 Asian (2%) patients in 2026. The estimated population in 1-3 and ≥4 prior LOT combined by payer type would be 28,016 Medicare (69%) and 12,852 commercial (31%) patients in 2024 and would include 22,702 Medicare (70%) and 9,789 commercial (30%) patients in 2026. **Conclusions:** The data from this MM disease progression model indicate that fewer patients are anticipated to move into the 1-3 prior LOT, PI-exposed, and lenalidomide-refractory relapsed/refractory MM (RRMM) and ≥4 prior LOT triple-class exposed RRMM settings in 2026 versus 2024.

Medicine, Ewha Womans University, Seoul, South Korea; [19]Inje University College of Medicine, Haeundae Paik Hospital

Introduction: The recent influx of novel agents with different mechanisms of action has led to rapid changes in treatment strategies and outcomes of multiple myeloma. However, in South Korea, where national health insurance service strongly influences drug selection, the lenalidomide based triplet remains the most effective treatment option for RRMM. The approval of KRd in 2018, followed by IRd in 2020, has raised questions about the most effective treatment strategies for patients with RRMM. **Methods:** We retrospectively reviewed the medical records of 182 RRMM patients treated with KRd (112) or IRd (70) at 17 centers in South Korea from May 2020 to April 2021. The primary endpoint was progression-free survival (PFS), and the secondary endpoints were overall survival (OS), overall response rate (ORR), and safety. **Results:** Median age (65 vs 66 yrs; p=0.38) and R-ISS at diagnosis (I: 13.3 vs 21.7%, II: 54.3 vs 48.3% and III: 32.4 vs 30.0%, p=0.38) were not significantly different between the two groups. The trial feasibility to participate in the clinical trial was similar in both groups (83.0 vs 87.1%, p=0.46). Prior treatment history and response to prior therapy were also similar in both groups. Approximately 92% of patients were treated as a second line and the number of patients who had received ASCT was the same at 49% in both groups. Patients with high risk cytogenetics were more likely to be treated with KRd (43.8 vs 18.0%, p=0.003) and the time from diagnosis to XRd treatment was longer in the IRd gorup (20.5 vs 33.7 mo, p=0.08). Patients in the KRd group received 13 cycles of treatment and patients in the IRd group received 15 cycles of treatment (median, p=0.1), with more dose modifications in the IRd group (30.1 vs 41.1%, p=0.023). ORR was not significantly different at 89.1 vs 87.0% (p=0.67), but CRR was better in the KRd group (45.5 vs 30.4%, p=0.046). Median PFS (19.1 vs 28.4 mo, p=0.08) showed a trend towards better outcomes in the IRd group, although not statistically significant, and median OS (31.6 vs not reached, p=0.02) was statistically significantly better in the IRd group. In subgroup analysis, patients with older than 65 years (HR 0.41, p=0.006), normal renal function (HR 0.52, p=0.045), ISS I or II (HR 0.5, p=0.03), extramedullary plasmacytoma (HR 0.35, p=0.02), and PR acheieved (HR 0.59, p=0.04) showed better PFS outcomes with IRd. In the safety analysis, hematologic toxicity, infection, and cardiac events were more frequent in the KRd group, and GI toxicity and skin rash were relatively more frequent in the IRd group. **Conclusions:** Our data showed the treatment outcomes of KRd and IRd in the real-world. Contrary to predictions based on clinical trials, the IRd group showed better survival data. Clinicians tended to choose KRd in the high risk group and it actually showed a deeper response. In contrast, the IRd group did not acheieve a deeper response, but the treatment response was found to be sustainted for a longer period of time.

Introduction: Despite novel therapeutics, multiple myeloma remains incurable with multiple relapses throughout the disease course. In relapsed/refractory multiple myeloma (RRMM), there are several medication classes approved in varying combinations, including anti-CD38 monoclonal antibodies, immunomodulatory drugs (IMiDs), and proteasome inhibitors (PIs), alkylating agents (ALK) amongst others. Despite these advances, there remains a lack of evidence for optimal treatment sequencing in RRMM. **Methods:** This is a single center, IRB approved retrospective study of patients with RRMM evaluated at our facility who received at least one treatment regimen for RRMM between the years 2016 and 2023. Data on patient characteristics, treatment regimens and responses were abstracted from the medical record. Responses were recorded by IMWG treatment response criteria as complete response (CR), very good partial response (VGPR), partial response (PR), stable disease (SD) and Progressive Disease (PD). Suspected complete response (stCR) was also recorded when bone marrow information was not available. Statistical analyses were conducted using R v4.3 software for computing. **Results:** 48 patients met inclusion criteria and were included in the analysis, 12 of whom had high risk cytogenetics, with 4 ultra-high risk (>1 high risk factor). 20 patients were International Staging System (ISS) stage I, 34 were stage II, and 4 were stage III. Any treatment line that was administered for relapsed disease post induction, autologous SCT consolidation and/or maintenance therapy or primary refractory disease were included. The top four combinations in addition to dexamethasone administered were anti-CD38 drugs combined with IMiD (CD38/IMiD; n=17), anti-CD38 drugs and PIs (CD38/PI; n=16), IMiDs and PIs (IMiD/PI; n=18), and PIs with alkylating agents (PI/ALK; n=19). Overall response rate (ORR; PR or better) was 64.7% (CD38/IMiD), 56.25% (CD38/PI), 65% (IMiD/PI), and 45% (PI/ALK); (p=0.451,chi -square). CR/stCR rates were: 23.5% (CD38/IMiD), 6.25% (CD38/PI), 25% (IMiD/PI), and 5% (PI/ALK); (p=0.144, chi-square). Median Time to next treatment (TNTT) was 43 weeks (CD38/IMiD), 25.5 weeks (CD38/PI), 67 weeks (IMiD/PI), and 45.5 weeks (PI/ALK); p = 0.198, Kruskal-Wallis). When comparing any doublet to triplet regimens, there was no statistical difference in either ORR, 57.69% vs. 52.8%, (p=0.593, chi-square) or CR/stCR rates, 11.53% vs. 13.48%, respectively (p=0.122,chi-square). **Conclusions:** Whilst no significant differences were observed between specific treatment combinations in our RRMM population, there were notable trends toward improved response rates and TNTT in CD38/IMiD and IMiD/PI groups when compared to CD38/PI group. Further, no statistically significant response rate in doublet vs. triplet regimens was observed, raising the question of selecting truly synergistic drug combinations as well as optimal number of drugs in a treatment

Comparison of daratumumab-based regimens as second-line therapy in relapsed/refractory MM

Charalampos Charalampous[1], Utkarsh Goel[1], Prashant Kapoor[1], Moritz Binder[1], Francis Buadi[1], Joselle Cook[1], David Dingli[1], Angela Dispenzieri[1], Amie Fonder[1], Morie Gertz[1], Wilson Gonsalves[1], Suzanne Hayman[1], Miriam Hobbs[1], Yi Hwa[1], Taxiarchis Kourelis[1], Martha Lacy[1], Nelson Leung[1], Yi Lin[1], Rahma Warsame[1], Robert Kyle[1], Vincent Rajkumar[1], Shaji Kumar[1]

[1]Mayo Clinic

Introduction: The introduction of anti-CD38 antibodies (daratumumab) in the treatment landscape of multiple myeloma (MM) has increased the outcomes of patients with relapsed disease in recent years. However, the ideal combination of these drugs (Dara-IMiD vs. Dara-PI) in patients with relapsed MM is unclear. **Methods:** We reviewed MM patients treated with daratumumab as second-line therapy at our institution from January 1st, 2016, to June 31st, 2022, to assess the outcomes with the different combination therapies. We used the Kaplan-Meier method to estimate PFS from the first relapse. **Results:** We identified 404 patients with a median age of 63.6 years (range: 27.1 – 90.4). Most patients received triplet induction therapy (94%) and upfront transplant (69%) as primary therapy. At the time of Dara initiation, 40% were refractory to IMiDs, 23% to PIs, 19% to both, and 19% to neither drug. Patients treated with Dara-IMiD had significantly better PFS than Dara-PI (28.7 months vs. 13.5 months, p< 0.01, respectively). When stratifying patients based on FISH classification, we found that both high-risk patients (25.3 vs. 8.1 months, p=0.01, respectively) and standard-risk patients (45.5 vs. 17 months, p< 0.01, respectively) benefited significantly from the Dara-IMiD regimen. Among patients treated with Dara-IMiD, those already refractory to IMiDs from the first line had significantly shorter PFS than those without IMiD resistance (14.6 vs. 43.3 months, p< 0.01, respectively). In addition, the lenalidomide-based combination resulted in significantly better PFS compared to pomalidomide in our cohort (39.4 vs. 22.4 months, p< 0.01, respectively). However, no difference was found in the IMiD refractory population (14.2 vs. 17.8 months, respectively). Finally, no significant differences were seen between Dara-IMiD and Dara-PI in patients only refractory to IMiD (16.2 vs. 12.8 months, p=NS, respectively). **Conclusions:** While further studies are required to adjudicate the best combination, we conclude that Dara-IMiD might be more effective in patients with relapsed MM, especially for patients not refractory to IMiDs at first relapse.

Ranking importance of prognostic factors for relapsed/refractory multiple myeloma (RRMM): international physician panel consensus following a systematic review of the literature

Shaji Kumar[1], Xavier Leleu[2], Katja Weisel[3], Rakesh Popat[4], Beatrice Suero[5], Samantha Craigie[5], Paul Spin[5], Christian Hampp[6], Wenzhen Ge[6], Qiufei Ma[6], Sundar Jagannath[7]

[1]Mayo Clinic, Rochester, MN, US; [2]Hospital La Mileterie, Poitiers, France; [3]University Medical Center of Hamburg-Eppendorf, Hamburg, Germany; [4]NIHR UCLH Clinical Research Facility; [5]EVERSANA; [6]Regeneron; [7]Mount Sinai Medical Center, New York, NY, USA

Introduction: Multiple myeloma (MM) is a highly heterogenous and incurable malignancy. Nearly all patients eventually relapse and/or become refractory to treatment. Patients with relapsed and/or refractory MM (RRMM) typically have poor outcomes, and prognosis worsens with exposure and/or refractoriness to multiple therapies. There is a high unmet need among RRMM patients and there is no single standard of care. Real-world data (RWD) can be used to understand outcomes with currently available therapies and to establish benchmarks for clinical trials. When comparing outcomes in single-arm trials to RWD, it is best practice to pre-specify confounders for adjustment. A systematic, evidence-based, and clinically validated method to identify and rank prognostic factors for pre-specification in comparative RRMM studies is currently lacking. The objective of this study was to identify and rank prognostic factors relevant to treatment outcomes in RRMM based on physician panel consensus. **Methods:** A systematic literature review (SLR; Kumar 2023, PROSPERO CRD42022330369) identified prognostic factors in RRMM that were significantly associated (p< 0.05) with outcomes. Factors associated with objective response rate (ORR) and/or overall survival (OS) and were reported in at least two studies were validated by a clinical expert and included in the ranking process. A panel of five international (United States, France, Germany, UK) MM clinical experts was assembled to confirm the variables identified in the SLR and to rank the prognostic factors. The panel was asked to organize the factors into five groups, with each group representing the level of importance of in terms of predicting outcomes in RRMM. Initial rankings were performed independently. Pooled rankings were calculated by averaging across the experts' rankings on a scale of 1 (least important) – 5 (most important). The pooled rankings and rank differences were presented to the panel for discussion. There were two rounds of panel voting. If 50% of the panel disagreed with the pooled rankings, another round of individual ranking was conducted. The final rankings were determined via consensus based on all (100%) panelists agreeing or strongly agreeing with the pooled rankings. **Results:** The SLR identified 29 factors associated with OS and/or ORR that were reported in at least two studies. Six factors were excluded for redundancy and two were added based on clinical expert opinion. A total of 25 factors were included in the ranking process. The six most important prognostic factors in RRMM were cytogenetic risk, age, refractory status, disease stage,

regimen for improved efficacy and decreased treatment related toxicity.

Introduction: The introduction of anti-CD38 antibodies (daratumumab) in the treatment landscape of multiple myeloma (MM) has increased the outcomes of patients with relapsed disease in recent years. However, the ideal combination of these drugs (Dara-IMiD vs. Dara-PI) in patients with relapsed MM is unclear. **Methods:** We reviewed MM patients treated with daratumumab as second-line therapy at our institution from January 1st, 2016, to June 31st, 2022, to assess the outcomes with the different combination therapies. We used the Kaplan-Meier method to estimate PFS from the first relapse. **Results:** We identified 404 patients with a median age of 63.6 years (range: 27.1 – 90.4). Most patients received triplet induction therapy (94%) and upfront transplant (69%) as primary therapy. At the time of Dara initiation, 40% were refractory to IMiDs, 23% to PIs, 19% to both, and 19% to neither drug. Patients treated with Dara-IMiD had significantly better PFS than Dara-PI (28.7 months vs. 13.5 months, p< 0.01, respectively). When stratifying patients based on FISH classification, we found that both high-risk patients (25.3 vs. 8.1 months, p=0.01, respectively) and standard-risk patients (45.5 vs. 17 months, p< 0.01, respectively) benefited significantly from the Dara-IMiD regimen. Among patients treated with Dara-IMiD, those already refractory to IMiDs from the first line had significantly shorter PFS than those without IMiD resistance (14.6 vs. 43.3 months, p< 0.01, respectively). In addition, the lenalidomide-based combination resulted in significantly better PFS compared to pomalidomide in our cohort (39.4 vs. 22.4 months, p< 0.01, respectively). However, no difference was found in the IMiD refractory population (14.2 vs. 17.8 months, respectively). Finally, no significant differences were seen between Dara-IMiD and Dara-PI in patients only refractory to IMiD (16.2 vs. 12.8 months, p=NS, respectively). **Conclusions:** While further studies are required to adjudicate the best combination, we conclude that Dara-IMiD might be more effective in patients with relapsed MM, especially for patients not refractory to IMiDs at first relapse.

Ranking importance of prognostic factors for relapsed/refractory multiple myeloma (RRMM): international physician panel consensus following a systematic review of the literature

Shaji Kumar[1], Xavier Leleu[2], Katja Weisel[3], Rakesh Popat[4], Beatrice Suero[5], Samantha Craigie[5], Paul Spin[5], Christian Hampp[6], Wenzhen Ge[6], Qiufei Ma[6], Sundar Jagannath[7]

[1]Mayo Clinic, Rochester, MN, US; [2]Hospital La Mileterie, Poitiers, France; [3]University Medical Center of Hamburg-Eppendorf, Hamburg, Germany; [4]NIHR UCLH Clinical Research Facility; [5]EVERSANA; [6]Regeneron; [7]Mount Sinai Medical Center, New York, NY, USA

Introduction: Multiple myeloma (MM) is a highly heterogenous and incurable malignancy. Nearly all patients eventually relapse and/or become refractory to treatment. Patients with relapsed and/or refractory MM (RRMM) typically have poor outcomes, and prognosis worsens with exposure and/or refractoriness to multiple therapies. There is a high unmet need among RRMM patients and there is no single standard of care. Real-world data (RWD) can be used to understand outcomes with currently available therapies and to establish benchmarks for clinical trials. When comparing outcomes in single-arm trials to RWD, it is best practice to pre-specify confounders for adjustment. A systematic, evidence-based, and clinically validated method to identify and rank prognostic factors for pre-specification in comparative RRMM studies is currently lacking. The objective of this study was to identify and rank prognostic factors relevant to treatment outcomes in RRMM based on physician panel consensus. **Methods:** A systematic literature review (SLR; Kumar 2023, PROSPERO CRD42022330369) identified prognostic factors in RRMM that were significantly associated (p< 0.05) with outcomes. Factors associated with objective response rate (ORR) and/or overall survival (OS) and were reported in at least two studies were validated by a clinical expert and included in the ranking process. A panel of five international (United States, France, Germany, UK) MM clinical experts was assembled to confirm the variables identified in the SLR and to rank the prognostic factors. The panel was asked to organize the factors into five groups, with each group representing the level of importance of in terms of predicting outcomes in RRMM. Initial rankings were performed independently. Pooled rankings were calculated by averaging across the experts' rankings on a scale of 1 (least important) – 5 (most important). The pooled rankings and rank differences were presented to the panel for discussion. There were two rounds of panel voting. If 50% of the panel disagreed with the pooled rankings, another round of individual ranking was conducted. The final rankings were determined via consensus based on all (100%) panelists agreeing or strongly agreeing with the pooled rankings. **Results:** The SLR identified 29 factors associated with OS and/or ORR that were reported in at least two studies. Six factors were excluded for redundancy and two were added based on clinical expert opinion. A total of 25 factors were included in the ranking process. The six most important prognostic factors in RRMM were cytogenetic risk, age, refractory status, disease stage,

regimen for improved efficacy and decreased treatment related toxicity.

Introduction: The introduction of anti-CD38 antibodies (daratumumab) in the treatment landscape of multiple myeloma (MM) has increased the outcomes of patients with relapsed disease in recent years. However, the ideal combination of these drugs (Dara-IMiD vs. Dara-PI) in patients with relapsed MM is unclear. **Methods:** We reviewed MM patients treated with daratumumab as second-line therapy at our institution from January 1st, 2016, to June 31st, 2022, to assess the outcomes with the different combination therapies. We used the Kaplan-Meier method to estimate PFS from the first relapse. **Results:** We identified 404 patients with a median age of 63.6 years (range: 27.1 – 90.4). Most patients received triplet induction therapy (94%) and upfront transplant (69%) as primary therapy. At the time of Dara initiation, 40% were refractory to IMiDs, 23% to PIs, 19% to both, and 19% to neither drug. Patients treated with Dara-IMiD had significantly better PFS than Dara-PI (28.7 months vs. 13.5 months, p< 0.01, respectively). When stratifying patients based on FISH classification, we found that both high-risk patients (25.3 vs. 8.1 months, p=0.01, respectively) and standard-risk patients (45.5 vs. 17 months, p< 0.01, respectively) benefited significantly from the Dara-IMiD regimen. Among patients treated with Dara-IMiD, those already refractory to IMiDs from the first line had significantly shorter PFS than those without IMiD resistance (14.6 vs. 43.3 months, p< 0.01, respectively). In addition, the lenalidomide-based combination resulted in significantly better PFS compared to pomalidomide in our cohort (39.4 vs. 22.4 months, p< 0.01, respectively). However, no difference was found in the IMiD refractory population (14.2 vs. 17.8 months, respectively). Finally, no significant differences were seen between Dara-IMiD and Dara-PI in patients only refractory to IMiD (16.2 vs. 12.8 months, p=NS, respectively). **Conclusions:** While further studies are required to adjudicate the best combination, we conclude that Dara-IMiD might be more effective in patients with relapsed MM, especially for patients not refractory to IMiDs at first relapse.

Ranking importance of prognostic factors for relapsed/refractory multiple myeloma (RRMM): international physician panel consensus following a systematic review of the literature

Shaji Kumar[1], Xavier Leleu[2], Katja Weisel[3], Rakesh Popat[4], Beatrice Suero[5], Samantha Craigie[5], Paul Spin[5], Christian Hampp[6], Wenzhen Ge[6], Qiufei Ma[6], Sundar Jagannath[7]

[1]Mayo Clinic, Rochester, MN, US; [2]Hospital La Mileterie, Poitiers, France; [3]University Medical Center of Hamburg-Eppendorf, Hamburg, Germany; [4]NIHR UCLH Clinical Research Facility; [5]EVERSANA; [6]Regeneron; [7]Mount Sinai Medical Center, New York, NY, USA

Introduction: Multiple myeloma (MM) is a highly heterogenous and incurable malignancy. Nearly all patients eventually relapse and/or become refractory to treatment. Patients with relapsed and/or refractory MM (RRMM) typically have poor outcomes, and prognosis worsens with exposure and/or refractoriness to multiple therapies. There is a high unmet need among RRMM patients and there is no single standard of care. Real-world data (RWD) can be used to understand outcomes with currently available therapies and to establish benchmarks for clinical trials. When comparing outcomes in single-arm trials to RWD, it is best practice to pre-specify confounders for adjustment. A systematic, evidence-based, and clinically validated method to identify and rank prognostic factors for pre-specification in comparative RRMM studies is currently lacking. The objective of this study was to identify and rank prognostic factors relevant to treatment outcomes in RRMM based on physician panel consensus. **Methods:** A systematic literature review (SLR; Kumar 2023, PROSPERO CRD42022330369) identified prognostic factors in RRMM that were significantly associated (p< 0.05) with outcomes. Factors associated with objective response rate (ORR) and/or overall survival (OS) and were reported in at least two studies were validated by a clinical expert and included in the ranking process. A panel of five international (United States, France, Germany, UK) MM clinical experts was assembled to confirm the variables identified in the SLR and to rank the prognostic factors. The panel was asked to organize the factors into five groups, with each group representing the level of importance of in terms of predicting outcomes in RRMM. Initial rankings were performed independently. Pooled rankings were calculated by averaging across the experts' rankings on a scale of 1 (least important) – 5 (most important). The pooled rankings and rank differences were presented to the panel for discussion. There were two rounds of panel voting. If 50% of the panel disagreed with the pooled rankings, another round of individual ranking was conducted. The final rankings were determined via consensus based on all (100%) panelists agreeing or strongly agreeing with the pooled rankings. **Results:** The SLR identified 29 factors associated with OS and/or ORR that were reported in at least two studies. Six factors were excluded for redundancy and two were added based on clinical expert opinion. A total of 25 factors were included in the ranking process. The six most important prognostic factors in RRMM were cytogenetic risk, age, refractory status, disease stage,

performance status, and extramedullary disease/plasmacytoma. All panelists agreed with the final rankings. **Conclusions:** This is the first prognostic factor ranking study in RRMM based on international physician panel consensus. Results from this prognostic factor ranking can inform the selection of variables in pre-specified comparative analyses especially between clinical trials and RWD.

Systematic literature review of prognostic factors for relapsed/refractory multiple myeloma

Shaji Kumar[1], Xavier Leleu[2], Katja Weisel[3], Rakesh Popat[4], Samantha Craigie[5], Leena Patel[5], Abril Oliva Ramirez[5], Wenzhen Ge[6], Qiufei Ma[6], Christian Hampp[6], Sundar Jagannath[7]

[1]Mayo Clinic, Rochester, MN, US; [2]Hospital La Mileterie, Poitiers, France; [3]University Medical Center of Hamburg-Eppendorf, Hamburg, Germany; [4]NIHR UCLH Clinical Research Facility; [5]EVERSANA; [6]Regeneron; [7]Mount Sinai Medical Center, New York, NY, USA

Introduction: Patients with relapsed and/or refractory multiple myeloma (RRMM) have a poor prognosis that is further reduced when exposed to multiple therapies. Although several studies have identified factors prognostic of outcomes in patients with RRMM, an up-to-date synthesis is lacking. A systematic and evidence-based approach to identify relevant prognostic factors to support RRMM research is needed in a rapidly changing treatment landscape. Our objective was to conduct a systematic literature review (SLR) of prognostic factors associated with response (objective, complete, and partial response rates, duration of response) and survival (overall and progression-free survival) outcomes in patients with RRMM. **Methods:** Ovid MEDLINE and Embase were searched for clinical trials and observational studies published between January 1, 2016 and April 14, 2022. Eligible studies included RRMM patients and an assessment of prognostic significance of any factor on an outcome of interest via multivariate analysis. Two independent reviewers assessed eligibility, with discrepancies resolved by consensus or a third independent reviewer. Data were extracted using standardized templates. Factors statistically significantly associated with an outcome of interest ($p < 0.05$, or confidence interval excluding the null value) were extracted. Study quality was assessed using the Quality in Prognosis Studies (QUIPS) tool. Data were summarized descriptively. **Results:** Of 5,349 records identified, 130 records reporting on 125 unique studies (23 clinical trials and 102 observational studies) were included. The most common limitations in study quality were related to sample representativeness and control of confounders. Ninety-seven factors were significantly associated with at least one outcome in at least one study. The most commonly identified factors were disease stage (n = 27 studies), age (n = 20), prior lines of therapy (n = 20), best response to index therapy (n = 20), cytogenetic risk (n = 19), lactate dehydrogenase (LDH; n = 12), extramedullary disease/plasmacytoma (EMP) (n = 12), and performance status (PS) (n = 10). Worse survival was associated with higher disease stage, older age, more prior lines of therapy, poorer response, high-risk cytogenetics, elevated LDH levels, EMP presence, and worse PS. Worse response was associated with higher disease stage, younger age, more prior lines of therapy, high-risk cytogenetics, and worse PS. Associations between factors and outcomes were largely consistent across studies, although conflicting associations were noted in < 10% of studies; in some studies, poor reporting limited the ability to ascertain the direction of associations. **Conclusions:** To our best knowledge, this is the first SLR to investigate prognostic factors for an RRMM population. This work provides a comprehensive evidence base for factors prognostic of response and survival outcomes in patients with RRMM.

Introduction: Carfilzomib, the second generation proteasome inhibitor (PI), in combination with lenalidomide land dexamethasone (KRd) significantly improved the survival of relapsed and/or refractory multiple myeloma (RRMM) patients. However, the real-world outcome of KRd in a large cohort of Asian MM patient is still lacking. The aim of this study was to analyze the effectiveness and toxicity profile of KRd regimen especially focused on clinical trial eligibility and high-risk clinical factors in Korean RRMM patients outside of the clinical trial. **Methods:** Retrospective data of 364 RRMM patients who have received KRd regimen between February, 2018 and October, 2020, was collected from 21 centers participating in the Korean multiple myeloma working party (KMMWP). Clinical trial ineligibility was defined by patient- and treatment-related features that were insufficient to meet the eligibility criteria for ASPIRE trial. **Results:** The median age was 63 years (range, 28-85). Forty-nine percent of patients were trial-ineligible. Among the 355 patients whose response were evaluable, overall response rate was 90%, including a very good partial response, a complete response (CR) and a stringent CR of 25%, 32% and 6%. Among the 62 patients who were evaluated for minimal residual disease (MRD) by EuroFlow standard operation procedure, 36% (22 of 62) were Flow MRD-negative. With a median follow-up duration of 34.8 months (range, 0.00-61.5), the median progression-free survival (PFS) and overall survival (OS) were26.4 months (95% confidence interval, CI, 23.1-29.7 months), and not reached. Trial-ineligibility affected to a significant decrease of PFS and OS after KRd treatment. High-risk disease-related factors, high-risk cytogenetics at diagnosis of MM, EMD, doubling of M protein, and symptomatic MM at the time of KRd treatment affected poorly on PFS by univariate and multivariate analysis. Additionally, EMD, doubling of M protein, and symptomatic MM at the time of KRd treatment affected poorly on OS by univariate and multivariate analysis. Hematologic toxicities were more commonly observed than non-hematologic adverse events (AEs). The most common grade 3 or higher toxicities were neutropenia, followed by infections, fatigue, and acute kidney injuries. Grade 3 or higher cardiovascular AEs were observed in less than 5 percent of the patients. **Conclusions:** KRd treatment for real-world Korean RRMM patients was highly effective with a tolerable AE profile. Trial-ineligible characteristics and high-risk disease-related features affected poorly to progression-free and overall survival of RRMM patients treated with KRd regimen, which necessitates more effective and tolerable new agents and combination therapies for those patients. This work was supported by Amgen (Grant number: ISS20217193).

Introduction: Despite clinical advances in multiple myeloma (MM), most patients are refractory to treatment or relapse and eventually become refractory. Patients who have been exposed to the 3 main drug classes used to treat MM (immunomodulatory imide drug [IMiD] agents, proteasome inhibitors [PI] and anti-CD38 monoclonal antibodies [mAbs]) – i.e. triple-class exposed (TCE) – have generally poor clinical outcomes. As novel agents become available, it is important to understand their potential benefit to patients with TCE MM. This study described the treatment patterns and clinical outcomes in patients with TCE MM in real-world clinical practice in the United States. **Methods:** We analyzed prospectively collected data from the Connect® MM Disease Registry (NCT01081028). The current study was conducted in multiple myeloma patients enrolled in the Connect MM® registry who became TCE from Nov 16, 2015 to Dec 31, 2020 and who had received an index treatment post-TCE status. The earliest available end date of the third treatment class was considered as the date patients became TCE. If patients received a subsequent line of treatment post-TCE date, that first treatment was defined as the index treatment and treatment initiation date was defined as the index date. Data analyzed included demographics, disease characteristics, prior treatment and class exposure/refractoriness, index treatments and classes, response rates (overall, complete, very good partial, and partial), progression-free survival (PFS), overall survival (OS), and time to progression (TTP). **Results:** The Connect MM Disease Registry includes 317 patients with TCE MM, of whom 215 had received an index treatment post-TCE. Median follow-up from the index date was 11.1 months. Median age of index-treated patients was 68 years, 61% were male, 86% were White, 81% were from a community practice setting. Patients received 3 median lines of treatment (range, 1–9) before index treatment; 83% were IMiD agent refractory, 81% were anti-CD38 mAb refractory, 68% were double-class refractory (IMiD agent and PI), 56% were triple-class refractory, and 9% were penta-refractory. Index treatments were varied (101 monotherapy or combination regimens in total) and carfilzomib/dexamethasone (DEX) (7.4%) and daratumumab/pomalidomide/DEX (7.0%) were the most commonly used treatments. Overall response and complete response rates among patients with TCE MM were 31.6% and 5.1%, respectively; median PFS with the index treatment was 4.4 months (95% CI, 3.0–5.6); median OS was 12.5 months (95% CI, 10.2–15.3), and TTP was 6.3 months (95% CI, 4.6–8.6). **Conclusions:** In the real-world prospective Connect MM Disease Registry, patients with TCE MM had poor response and survival outcomes, with TCE occurring at a median of 3 prior lines of therapy. This study highlights the need for more efficacious and accessible novel

Introduction: Carfilzomib, the second generation proteasome inhibitor (PI), in combination with lenalidomide land dexamethasone (KRd) significantly improved the survival of relapsed and/or refractory multiple myeloma (RRMM) patients. However, the real-world outcome of KRd in a large cohort of Asian MM patient is still lacking. The aim of this study was to analyze the effectiveness and toxicity profile of KRd regimen especially focused on clinical trial eligibility and high-risk clinical factors in Korean RRMM patients outside of the clinical trial. **Methods:** Retrospective data of 364 RRMM patients who have received KRd regimen between February, 2018 and October, 2020, was collected from 21 centers participating in the Korean multiple myeloma working party (KMMWP). Clinical trial ineligibility was defined by patient- and treatment-related features that were insufficient to meet the eligibility criteria for ASPIRE trial. **Results:** The median age was 63 years (range, 28-85). Forty-nine percent of patients were trial-ineligible. Among the 355 patients whose response were evaluable, overall response rate was 90%, including a very good partial response, a complete response (CR) and a stringent CR of 25%, 32% and 6%. Among the 62 patients who were evaluated for minimal residual disease (MRD) by EuroFlow standard operation procedure, 36% (22 of 62) were Flow MRD-negative. With a median follow-up duration of 34.8 months (range, 0.00-61.5), the median progression-free survival (PFS) and overall survival (OS) were26.4 months (95% confidence interval, CI, 23.1-29.7 months), and not reached. Trial-ineligibility affected to a significant decrease of PFS and OS after KRd treatment. High-risk disease-related factors, high-risk cytogenetics at diagnosis of MM, EMD, doubling of M protein, and symptomatic MM at the time of KRd treatment affected poorly on PFS by univariate and multivariate analysis. Additionally, EMD, doubling of M protein, and symptomatic MM at the time of KRd treatment affected poorly on OS by univariate and multivariate analysis. Hematologic toxicities were more commonly observed than non-hematologic adverse events (AEs). The most common grade 3 or higher toxicities were neutropenia, followed by infections, fatigue, and acute kidney injuries. Grade 3 or higher cardiovascular AEs were observed in less than 5 percent of the patients. **Conclusions:** KRd treatment for real-world Korean RRMM patients was highly effective with a tolerable AE profile. Trial-ineligible characteristics and high-risk disease-related features affected poorly to progression-free and overall survival of RRMM patients treated with KRd regimen, which necessitates more effective and tolerable new agents and combination therapies for those patients. This work was supported by Amgen (Grant number: ISS20217193).

Introduction: Patients (pts) with RRMM are at increased risk for severe infections due to immunosuppression related to underlying MM as well as anti-MM therapies. As a result, management guidelines include recommendations for anti-infective prophylaxis in high-risk pts, including immunoglobulin (Ig) replacement therapy for hypogammaglobulinemia. However, sparse data exist demonstrating the impact of Ig replacement on the incidence of infection in this population. **Methods:** A post-hoc analysis evaluating the impact of Ig replacement and hypogammaglobulinema on infections was conducted in pts enrolled in MagnetisMM-3 (NCT04649359), a Phase 2 study of SC elranatamab (BCMA x CD3 bispecific mAb) in pts with RRMM. Exposure adjusted infection rates (EAIR) in the following subgroups were analyzed: On vs Off Ig replacement therapy (n=187); Without vs With hypogammaglobulinemia (in pts with quantitative Ig data available, n=137). Infection events were defined as any distinct infection event or as any in increase in grade in a single infection event. "On Ig" period was defined as the period between the administration of Ig replacement + 30 days. Hypogammaglobulinemia was defined as IgG < 400 mg/dL. For pts with non-IgG myeloma, quantitative IgG results were used. For pts with IgG myeloma, functional IgG levels were determined by subtracting the M-spike in SPEP from the quantitative IgG result. EAIR were calculated as the number infection events in each period divided by the total time in months in each period. **Results:** 187 pts received elranatamab. At baseline, among pts with baseline quantitative Ig data available (n=124), 93.5% had immune paresis (defined as ≥2 uninvolved Ig < LLN); 41.2% of pts received Ig replacement during the treatment period. The median (range) time On and Off Ig replacement was 4.0 (0.3, 26.2) and 5.0 (0.6, 20.5) months respectively, while the median (range) time without and with hypogammaglobulinemia was 4.9 (0.03, 23.1) and 6.9 (0.9, 19.1). The monthly EAIR in pts On vs Off Ig replacement were 0.162 (95% CI: 0.128, 0.203) vs 0.305 (95% CI: 0.275, 0.337) for any grade infection, and 0.041 (95% CI: 0.025, 0.064) vs 0.116 (95% CI: 0.098, 0.136) for Grade ≥3 infection, respectively. In pts without vs with hypogammaglobulinemia, the monthly EAIR were 0.182 (95% CI: 0.150, 0.219) vs 0.307 (95% CI: 0.271, 0.354) for any grade infection, and 0.039 (95% CI: 0.025, 0.059) vs 0.122 (95% CI: 0.100, 0.147) for Grade ≥3 infection, respectively. Similar results were observed across infection types (bacterial, fungal, viral). **Conclusions:** In this Phase 2 study of pts with RRMM treated with elranatamab, IgG levels ≥400 mg/dL or Ig replacement therapy were associated with a decreased infection rate, including the rate of Grade ≥3 infections. These data support the continued need for close monitoring of Ig levels during treatment and the benefit of Ig replacement therapy in the management of pts with RRMM treated with BCMA-directed bispecific antibodies.

Introduction: IMAGE was a non-interventional, retrospective cohort study of patients (pts) with relapsed/refractory multiple myeloma (RRMM) enrolled in early access programs (EAPs) for isatuximab with pomalidomide and dexamethasone (Isa-Pd) in France. The median progression-free survival (mPFS) in the overall effectiveness population was 12.4 months (mo) after a median follow-up of 14.2 mo. Here, we report results from the subgroup analysis of the IMAGE study based on subgroups of interest – elderly (aged ≥75), severe renal impairment (< 30 mL/min/1.73m^2) and high-risk (HR) cytogenetics. **Methods:** IMAGE used medical records of adult pts with RRMM who received ≥1 dose of Isa under EAPs. Effectiveness analysis was restricted to pts with ≥1 year of follow-up after Isa initiation, while safety analysis included all pts who received

treatments for patients with TCE MM, irrespective of number of lines of prior therapy.

Introduction: IMAGE was a non-interventional, retrospective cohort study of patients (pts) with relapsed/refractory multiple myeloma (RRMM) enrolled in early access programs (EAPs) for isatuximab with pomalidomide and dexamethasone (Isa-Pd) in France. The median progression-free survival (mPFS) in the overall effectiveness population was 12.4 months (mo) after a median follow-up of 14.2 mo. Here, we report results from the subgroup analysis of the IMAGE study based on subgroups of interest – elderly (aged ≥75), severe renal impairment (< 30 mL/min/1.73m^2) and high-risk (HR) cytogenetics. **Methods:** IMAGE used medical records of adult pts with RRMM who received ≥1 dose of Isa under EAPs. Effectiveness analysis was restricted to pts with ≥1 year of follow-up after Isa initiation, while safety analysis included all pts who received

≥1 dose of Isa. HR cytogenetics was the detection of at least one of the following: del(17p), t(4;14), and t(14;16). PFS was defined as the time from start of Isa-Pd to date of disease progression, as reported in the medical record, or death. Verbatim terms for adverse events (AEs) were coded using the Medical Dictionary for Regulatory Activities, and AEs were not graded for severity. **Results:** The total effectiveness population was 294, while safety population was 299. 83 pts were aged ≥75, 25 pts had renal function < 30 mL/min/1.73m^2, and 40 pts had HR cytogenetics. 120 pts had unknown cytogenetic risk. Majority of pts across all subgroups had International Staging System Stage III disease, and all subgroups had a median 2 prior lines of therapy, except for pts with renal impairment who had a median 3 prior lines of therapy. Similar to the overall effectiveness population, around 70% of pts in all subgroups were refractory to lenalidomide and their last line of therapy. The mPFS was 13.2 (95% CI: 6.8-15.0) mo, 10.0 (95% CI: 2.4-18.6) mo, and 7.6 (95% CI: 2.8-Not reached) mo in pts aged ≥75, with severe renal impairment, and HR cytogenetics, respectively. Overall response and very good partial response rates were 51.8% and 26.5% in elderly pts, 68.0% and 48.0% in pts with severe renal impairment, and 32.5% and 25.0% in pts with HR cytogenetics. In the overall effectiveness population, ORR and VGPR were 46.3% and 27.9%. 28.9% of elderly, 25.0% of HR cytogenetics, and 30.8% of renal impaired pts had at least one AE. 1 elderly pt and 1 pt with HR cytogenetics had an AE leading to permanent discontinuation of Isa. The incidence of neutropenia was 8.3%, 0%, and 7.5% in elderly, renal impaired, and HR cytogenetics pts. Infections and infestations occurred in 3 pts in the overall safety population — 2 in elderly, 1 in renal impaired, and 0 in HR cytogenetics pts. **Conclusions:** The effectiveness and safety profiles across elderly, renal impaired, and HR cytogenetics subgroups were similar to those in the overall effectiveness population. The results of this subgroup analyses continue to support Isa-Pd for treatment of RRMM across subgroups.

Introduction: Patients with relapsed/refractory multiple myeloma (RRMM) treated with anti-B cell maturation antigen (BCMA) chimeric antigen receptor-T (CAR-T) cell therapy frequently experience the hematologic toxicity of persistent thrombocytopenia. Our aim was to develop a model that distinguishes between patients at high and low risk for prolonged thrombocytopenia, which may be useful for risk-adapted treatment of hematologic toxicity. **Methods:** We retrospectively analyzed data from a phase 1b/2 trial of 103 RRMM patients treated with CT103A, a fully human anti- BCMA CAR -T (NCT05066646). Recovery of thrombocytopenia was defined as a rebound in platelet count (PLT) to 50×10^9/L. Patients were divided into three groups: non-thrombocytopenia (patients whose PLT never decreased to 50×10^9/L post-infusion), non-sustained thrombocytopenia (patients whose PLT recovered to 50×10^9/L within two months post-infusion), and prolonged thrombocytopenia (patients whose PLT never recovered to 50×10^9/L within two months post- infusion). Receiver operating characteristics (ROC) curve was used to determine baseline clinical characteristics associated with the recovery of prolonged thrombocytopenia. Biomarkers with a P value of 0.6, and a concomitant P value of < 0.05 were used for modeling. Multiple thresholds were tested; the final threshold was set as 1 based on the optimal Youden index, and specificity was ≥ 0.75. **Results:** Ultimately, PLT, C reaction protein, plasma cells in bone marrow, hemoglobin, and Ig Ferritin at baseline were determined to be associated with the recovery of thrombocytopenia and were used to establish the model (Table 1). This model allows prediction of recovery from thrombocytopenia based on baseline data. PLT and hemoglobin levels could partially reflect bone marrow reserve, and plasma cells in bone marrow and ferritin indirectly influence tumor burden. High-risk patients with a model score of 5 or higher may require further supportive care after infusion, including

Table 1 Prolonged Thrombocytopenia Recovery Model

Baseline PLT: >161.5/μL (0 Point), 112.5-161.5 /μL (1 Point), <112.5/μL (2 Points)
Baseline CRP: <5.05 mg/L (0 Point), 5.05-23.95 mg/L (1 Point), >23.95 mg/L (2 Points)
Plasma Cell: <5.65% (0 Point), 5.65-51.05% (1 Point), >51.05% (2 Points)

Introduction: Polychemotherapy has been replaced by novel therapies in the management of Multiple Myeloma and is now reserved in the salvage setting despite limited published evidence. Commonly used regimens in this setting include D(T)-PACE and DCEP, which are multi-day continuous infusions, usually administered to patients with low comorbidities as inpatients. This study investigates the efficacy and safety of PCAB, a single day polychemotherapy in relapsed/refractory multiple myeloma (RRMM). **Methods:** This multisite retrospective study involved four Australian tertiary hospitals. Patients with RRMM who received PCAB chemotherapy ± one novel agent between 1/1/2012-1/5/2023 were included. PCAB comprises of cyclophosphamide 600mg/m^2, doxorubicin 30mg/m^2 and carmustine 30mg/m^2 day 1, and prednisone 60mg/m^2 day 15, given every 28 days for up to 12 cycles. Baseline clinical characteristics, treatment response, adverse events and hospitalisation duration were recorded. **Results:** Seventy-seven patients, median age 64 years (range 37-79) with median 4 (range 1-8) prior lines of therapy were included. Of these 76.6% had been exposed to both proteasome inhibitor and immunomodulatory drugs, and 63.6% had a previous autograft. Active extramedullary disease (EMD) and high-risk cytogenetics occurred in 35.1% and 58.0% of patients respectively. Forty-eight (62.3%) patients received only PCAB, while 29 (37.7%) received it in combination, most commonly with bortezomib (n=14) or thalidomide (n=7). After a median of 3 cycles (range 1-11), ORR was 38.4% (CR 5.5%) for the whole cohort, and 27.3% for those solely receiving PCAB. ORR in patients with EMD and high-risk cytogenetics were 30.8% and 42.9% respectively. A subsequent therapy was received in 72.7% of patients, including as bridge to CAR-T therapy (n=2), autograft (n=3) and allograft (n=3). Median PFS and OS were 4.0 months and 6.7 months respectively. Rate of any grade 3/4 cytopenia and febrile neutropenia was 76.2% and 44.3% respectively. Treatment-related deaths, all due to infections occurred in 6 patients (7.8%). Patients required inpatient management for a median of 3.6 days per 28 day cycle. Of patients who died, median 20.2% of days alive was spent as inpatient. **Conclusions:** PCAB has retained efficacy in RRMM including those with high-risk cytogenetics and EMD. It may have a role as bridging therapy deliverable in an outpatient setting. Infection related mortalities highlight need for careful monitoring in this heavily pre-treated cohort.

Introduction: Equecabtagene Autoleucel (Eque-cel) is a fully human B-cell maturation antigen (BCMA) targeted chimeric antigen receptor (CAR) T-cell therapy for relapsed/refractory multiple myeloma (RRMM). A phase 1b/2 study (FUMANBA-1) was conducted for Eque-cel in RRMM patients (NCT05066646). Here, we report the results of the FUMANBA-1 trial, which was conducted at 14 sites in China and had a median follow-up duration of 18.07 months (range: 0.4, 30.3). **Methods:** Participants were RRMM patients who had received at least three prior lines of therapy (with at least one proteasome inhibitor and one immunomodulator) and whose disease had progressed after the last line of therapy. Patients with prior BCMA CAR -T therapy were also included. On three consecutive days of lymphodepletion (500mg/m^2 cyclophosphamide and 30mg/m^2 fludarabine), patients received a single infusion of Eque-cel at a dose of 1×10^6 cells/kg. **Results:** As of December 31, 2022, 105 patients received Eque-cel with a

thrombopoietic growth factors and platelet transfusion. **Conclusions:** We analyzed the factors affecting thrombocytopenia in RRMM patients after anti BCMA CAR -T treatment and developed for the first time a predictive model for prolonged thrombocytopenia recovery. Prolonged thrombocytopenia may occur in patients with low bone marrow reserve and high tumor burden.

A subsequent therapy was received in 72.7% of patients, including as bridge to CAR-T therapy (n=2), autograft (n=3) and allograft (n=3). Median PFS and OS were 4.0 months and 6.7 months respectively. Rate of any grade 3/4 cytopenia and febrile neutropenia was 76.2% and 44.3% respectively. Treatment-related deaths, all due to infections occurred in 6 patients (7.8%). Patients required inpatient management for a median of 3.6 days per 28 day cycle. Of patients who died, median 20.2% of days alive was spent as inpatient. **Conclusions:** PCAB has retained efficacy in RRMM including those with high-risk cytogenetics and EMD. It may have a role as bridging therapy deliverable in an outpatient setting. Infection related mortalities highlight need for careful monitoring in this heavily pre-treated cohort.

Introduction: Equecabtagene Autoleucel (Eque-cel) is a fully human B-cell maturation antigen (BCMA) targeted chimeric antigen receptor (CAR) T-cell therapy for relapsed/refractory multiple myeloma (RRMM). A phase 1b/2 study (FUMANBA-1) was conducted for Eque-cel in RRMM patients (NCT05066646). Here, we report the results of the FUMANBA-1 trial, which was conducted at 14 sites in China and had a median follow-up duration of 18.07 months (range: 0.4, 30.3). **Methods:** Participants were RRMM patients who had received at least three prior lines of therapy (with at least one proteasome inhibitor and one immunomodulator) and whose disease had progressed after the last line of therapy. Patients with prior BCMA CAR -T therapy were also included. On three consecutive days of lymphodepletion (500mg/m^2 cyclophosphamide and 30mg/m^2 fludarabine), patients received a single infusion of Eque-cel at a dose of 1×10^6 cells/kg. **Results:** As of December 31, 2022, 105 patients received Eque-cel with a

median of 4 lines of prior therapy (range 3-23). 32.4% of patients had high-risk cytogenetic abnormalities (defined as at least one of del (17), t (4:14) and t (14:16) is positive), 13.3% had extramedullary disease (EMD), 11.4% had received prior BCMA CAR-T therapy, and 52.4% belonged to IgG-type MM. Of the 103 patients whose efficacy could be evaluated, 96.1% achieved a response, 77.7% achieved a complete response (CR) or a stringent CR. The 12-month PFS rate was 80.0% (95% CI: 70.33, 86.76). Patients without prior CAR-T therapy, patients who had already received three lines of treatment, and patients who were not IgG MM, achieved deeper responses, and the sCR/ CR rates were 82.4%, 96.3%, and 91.8%, respectively. Patients without high-risk cytogenetic abnormalities and without prior CAR-T therapy had better PFS rate, and 12-m PFS rates were 92.0% (95% CI: 80.07, 96.92) and 85.5% (95% CI: 75.75, 91.51), respectively. Ninety-seven of 103 (94.2%) evaluable patients achieved MRD-negativity, including all ≥ CR patients. 90.0% of patients achieved ≥CR were persistently MRD-negative for ≥12 months. CRS occurred in 93.3% (98/105) of patients, and only one was ≥ grade 3. The median time to onset was six days (range: 1-13), and the median duration was 5 days (range: 2-30). ICANS occurred in 2 patients who had either grade 1 or 2. Eque-cel expansion in peripheral blood peaked at 88001.13 copies/µg gDNA, and the median time to peak level was 12 days post-infusion. CAR Transgenes were still detectable in 50% (32/64) of patients 12 months and in 40% (4/10) of patients 24 months after infusion. Anti-CAR antibodies developed in only 20 (19.2%) patients after infusion. **Conclusions:** A profound and durable response can be achieved in RRMM patients treated with Eque-cel with a median follow-up of 18.07 months. Factors like prior CAR-T therapy, more prior lines of therapy and IgG-type MM could adversely impact the depth of response, and factors like prior CAR-T therapy or high-risk cytogenetic abnormalities might also reduce the PFS.

[1]London Health Sciences Centre, Western University, London, ON, Canada; [2]Princess Margaret Cancer Centre; [3]BC Cancer Agency; [4]Nova Scotia Health; [5]Canadian Myeloma Research Group; [6]Alberta Health Services, Edmonton, Alberta, Canada; [7]Tom Baker Cancer Center; [8]University of Ottawa; [9]Vancouver General Hospital, Vancouver, BC, Canada; [10]McMaster University, Hamilton, Ontario, Canada; [11]McGill University; [12]MUHC, Montreal, Quebec, Canada; [13]Memorial University of Newfoundland; [14]Saskatchewan Cancer Agency; [15]Saint John Regional Hospital; [16]Cancercare Manitoba; [17]Allan Blair Cancer Centre; [18]Maisonneuve-Rosemont Hospital Research Centre

Introduction: Multiple myeloma (MM) is an incurable plasma cell neoplasm characterized by multiple relapses. Typically, each subsequent line of therapy is associated with a shorter progression-free survival (PFS). There is paucity of data regarding the use and outcomes of third-line (3L) therapy. Our study assessed the regimens utilized and their long-term outcomes with 3L therapy in CMRG centres. **Methods:** This Canadian multicentre retrospective study utilized the CMRG database to track real-world outcomes of patients treated at major Canadian institutions. Eligibility included adult myeloma patients initiating 3L therapy between 1-Jan-2015 to 31-Dec-2020. **Results:** 1126 of 7911 patients fulfilled eligibility criteria and were included in the study. At MM diagnosis 205 (24%) had high-risk (HR) cytogenetics. Prior to 3L therapy, 482 (43%) had received ASCT, 998 (88%) lenalidomide (len), 996 (88%) bortezomib (bort), 109 (10%) CD38 monoclonal antibody (MoAb) and 53 (5%) pomalidomide. 106 of 1126 (9.4%) were triple-class exposed and/or refractory. At 3L, 548 patients (49%) received a triplet combination. 184 (16%) participated in clinical trials. Daratumumab (dara)-len-dex showed the best outcome with median duration of treatment (DOT) of 12.3 months and median time to next therapy (TTNT) of 32.2 followed by dara-bort-dex with DOT of 6 months and TTNT of 9.0. CD38 MoAb ± steroid, DOT=11 and TTNT=18.5. Outcomes with doublet combinations of IMiD (DOT= 5.7; TTNT=7.5) or proteasome inhibitors (PI) (DOT= 5.9; TTNT=8.9) were similar to dara-bort-dex. TTNT of 32 months was significantly better than 9 (p< 0.0001) and 18 months (p=0.001). Median PFS (mPFS) and OS from the start of 3L were stratified according to cytogenetics, previous ASCT, age, prior PI, len, pomalidomide, or CD38 MoAb. Overall mPFS was 7.5 (95%CI 6.5-8.5) months; dara-len-dex produced the best PFS: 21.4 (95%CI 16.0-28.7) months although HR patients in this group had a PFS of 10.7 [95%CI,4.4- 22.7] versus 21.4 (95%CI 16.0- 28.4) months for standard-risk. For those receiving doublets, mPFS was 6.7 (95% CI 5.6 -8.2) months. Median OS for all patients was 29.7 (95%CI 26.4-32.8) months. There was no significant difference between subgroups and type of treatment; however standard-risk dara-len-dex patients experienced a mOS of 42.9 (95%CI 34.8- 55.0) versus 29.1 (95%CI 13.2- 45.0) months in HR patients (p=0.100). Those without prior exposure to PI that were given triplets containing IMiD ± PI at 3L had the best OS: 37.3 (95%CI 27.2-48.7) months. Prior CD38 MoAb exposure negatively impacted 3L OS: 14.5 (95%CI 9.2-19.6) versus 32.6 (95% CI 28.8-36.0) months. The most common reason for discontinuation of 3L was MM progression (39%) followed by toxicity and death, each 9%. **Conclusions:** In Canadian myeloma centres, 3L patients have been preferably treated with triplet IMiD-based combinations with dara-len-dex showing the best outcomes. The time period assessed in this study reflects previous limited access to dara-based regimens at 2L in Canada.

median of 4 lines of prior therapy (range 3-23). 32.4% of patients had high-risk cytogenetic abnormalities (defined as at least one of del (17), t (4:14) and t (14:16) is positive), 13.3% had extramedullary disease (EMD), 11.4% had received prior BCMA CAR-T therapy, and 52.4% belonged to IgG-type MM. Of the 103 patients whose efficacy could be evaluated, 96.1% achieved a response, 77.7% achieved a complete response (CR) or a stringent CR. The 12-month PFS rate was 80.0% (95% CI: 70.33, 86.76). Patients without prior CAR-T therapy, patients who had already received three lines of treatment, and patients who were not IgG MM, achieved deeper responses, and the sCR/ CR rates were 82.4%, 96.3%, and 91.8%, respectively. Patients without high-risk cytogenetic abnormalities and without prior CAR-T therapy had better PFS rate, and 12-m PFS rates were 92.0% (95% CI: 80.07, 96.92) and 85.5% (95% CI: 75.75, 91.51), respectively. Ninety-seven of 103 (94.2%) evaluable patients achieved MRD-negativity, including all ≥ CR patients. 90.0% of patients achieved ≥CR were persistently MRD-negative for ≥12 months. [1]Banner MD Anderson Cancer Center, Gilbert, AZ; [2]University of California; [3]The Department of Medicine, University of Rochester Medical Center, Rochester, NY, USA; [4]Oregon Health and Science University; [5]Fred Hutch Cancer Center / University of Washington; [6]Roswell Park Comprehensive Cancer Center; [7]Mayo Clinic Arizona; [8]Hospital La Mileterie, Poitiers, France; [9]CHU de Nantes, Nantes, France; [10]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; [11]Catalan Institute of Oncology and Josep Carreras Institute, Hospital Germans Trias i Pujol, Badalona, Spain; [12]Colorado Blood Cancer Institute; [13]CHU de Lille, Lille, France; [14]Harpoon Therapeutics; [15]University of Kansas Cancer Center, KA, USA

Introduction: HPN217 is a B Cell Maturation Antigen (BCMA)-targeting tri-specific T cell engager (TCE). HPN217 contains three binding domains including anti-BCMA for MM cell binding, anti-albumin for half-life extension, and anti-CD3 for T cell engagement and activation. HPN217 is under investigation in patients (pts) with heavily pretreated relapsed/refractory MM (RRMM). **Methods:** This dose escalation study is evaluating both fixed and step dose regimens to assess the safety/pharmacology and early clinical activity of HPN217. Pts with RRMM who received at least 3 prior therapies including a proteasome inhibitor, immunomodulatory drug, and CD38 targeted therapy are eligible. Prior exposure to BCMA-targeting agent is permitted. Primary objectives include evaluation of safety, tolerability, pharmacokinetics, and determination of the Recommended Phase 2 Dose(s). Secondary objectives include preliminary efficacy. HPN217 is administered IV once weekly or once every 2 weeks. AEs are graded by CTCAE 5.0, and ASTCT for cytokine release syndrome (CRS). Clinical activity is assessed per IMWG Response Criteria. **Results:** As of 01May2023, 84 pts were treated with HPN217 across 14 dose escalation cohorts and 3 backfill cohorts; dose escalation up to 24 mg is complete; the target dose MTD has not been reached. Further dose/regimen optimization is ongoing in cohorts with doses of 12 mg QW and 24 mg (QW & Q2W). Across all cohorts, pts received a median (range) of 6 (2-19) prior lines of treatment (70% transplantation, 94% triple-exposed, 76% penta-exposed, 16% BCMA targeted therapy). Median age was 69 (38-85). 34 pts remain on treatment. The most common (≥25%) treatment emergent adverse events (TEAEs) were anemia (45%), fatigue (36%), cough and CRS (30%), diarrhea (27%), and nausea (25%). All CRS events were G1-G2 except one event of G3 CRS at 24 mg. Responses were observed at doses ≥ 2.15 mg. The 12 mg cohorts (n=19) have completed enrollment and follow-up is ongoing. At the 12 mg dose level, TEAEs reported in ≥25% of pts were fatigue and cough (47%), anemia (42%), hypokalemia (37%), hypophosphatemia (32%) and diarrhea (26%). CRS was reported in 16% of pts (all G1-2). Responses of PR or better have been reported in 11 (58%) pts, including 2 pts treated with prior BCMA CAR-T. Eight pts (42%) reported a best response of VGPR or better. Treatment is ongoing in 9 responders. **Conclusions:** Dose escalation of HPN217, a novel half-life extended BCMA-targeting TCE, has been completed; target dose MTD was not reached. The 12 mg QW regimen is well tolerated with a manageable adverse event profile, low rates of CRS (16%) and robust early clinical activity (58% ORR). Evaluation of regimens using 24 mg QW and Q2W is ongoing to inform the choice of an RP2D(s). NCT04184050.

Real-world treatment patterns and outcomes in lenalidomide refractory multiple myeloma patients in Europe: a real-world survey

Joaquín Martínez-López[1], João Mendes[2], Emily Luke[3], Caspian Kluth[3], Phoebe Salmon[3], Abigail Bailey[3], Amanda Ribbands[3], Francesca Gay[4]

[1]Hematología Hospital 12 de Octubre, Madrid, Spain; [2]Janssen-Cilag, Porto Salvo, Portugal; [3]Adelphi Real World, Bollington, UK; [4]Division of Hematology 1, Clinical trial unit AOU città della salute e della scienza, University of Torino

Introduction: Lenalidomide (LEN) is a standard treatment (tx) for multiple myeloma (MM), given in earlier tx lines until disease progression, with many patients (pts) becoming refractory (Ref) to LEN. Real-world data on tx patterns and outcomes in LEN Ref MM pts in earlier lines of therapy (LOT) is limited. **Methods:** Data were drawn from the Adelphi MM Disease Specific Programme™, a cross-sectional survey with retrospective data collection of haematologists/haem-oncologists conducted in Europe between May-Nov 2021. Physicians completed online record forms for their next 8 consulting adult pts with a confirmed diagnosis of MM and actively receiving tx. This included pts receiving: first line (1L) or second line (2L); third line (3L); fourth line and beyond (4L+); and tri-exposed (exposed to a proteasome inhibitor [PI], an immunomodulatory [IMiD], and an anti-CD38 targeted drug). Full tx history was collected, and only pts exposed to LEN who had received 1-3 prior LOT were analysed. Two patient populations were analysed: (1) LEN Ref status (LEN Ref and non-LEN Ref) at time of data collection and (2) LOT pts first became LEN Ref. Bivariate comparisons were made between the LOT pts first became LEN Ref. LEN Ref is defined by the International Myeloma Working Group, as progressive disease during LEN tx or within 60 days of discontinuation. **Results:** Of 1163 pts exposed to LEN who received 1-3 prior LOT, 528 (45%) were LEN Ref. Mean age was 71.1 years, 56% were male, and 77% were retired. 26% of LEN Ref and 30% of non-LEN Ref pts previously received an autologous stem cell transplant (ASCT). Of all LEN Ref pts, 41% had exposure to a PI and IMiD at 1L, 93% before 3L. 71% of LEN Ref pts with prior ASCT (n=137) received a PI and IMiD at 1L, 96% before 3L. For non-ASCT LEN Ref pts (n=391), 30% received a PI and IMiD at 1L, 90% before 3L. Of the LEN Ref pts, 24% (n=129) first became Ref after 1L, 63%

Introduction: Lenalidomide (LEN) is a standard treatment (tx) for multiple myeloma (MM), given in earlier tx lines until disease progression, with many patients (pts) becoming refractory (Ref) to LEN. Real-world data on tx patterns and outcomes in LEN Ref MM pts in earlier lines of therapy (LOT) is limited. **Methods:** Data were drawn from the Adelphi MM Disease Specific Programme™, a cross-sectional survey with retrospective data collection of haematologists/haem-oncologists conducted in Europe between May-Nov 2021. Physicians completed online record forms for their next 8 consulting adult pts with a confirmed diagnosis of MM and actively receiving tx. This included pts receiving: first line (1L) or second line (2L); third line (3L); fourth line and beyond (4L+); and tri-exposed (exposed to a proteasome inhibitor [PI], an immunomodulatory [IMiD], and an anti-CD38 targeted drug). Full tx history was collected, and only pts exposed to LEN who had received 1-3 prior LOT were analysed. Two patient populations were analysed: (1) LEN Ref status (LEN Ref and non-LEN Ref) at time of data collection and (2) LOT pts first became LEN Ref. Bivariate comparisons were made between the LOT pts first became LEN Ref. LEN Ref is defined by the International Myeloma Working Group, as progressive disease during LEN tx or within 60 days of discontinuation. **Results:** Of 1163 pts exposed to LEN who received 1-3 prior LOT, 528 (45%) were LEN Ref. Mean age was 71.1 years, 56% were male, and 77% were retired. 26% of LEN Ref and 30% of non-LEN Ref pts previously received an autologous stem cell transplant (ASCT). Of all LEN Ref pts, 41% had exposure to a PI and IMiD at 1L, 93% before 3L. 71% of LEN Ref pts with prior ASCT (n=137) received a PI and IMiD at 1L, 96% before 3L. For non-ASCT LEN Ref pts (n=391), 30% received a PI and IMiD at 1L, 90% before 3L. Of the LEN Ref pts, 24% (n=129) first became Ref after 1L, 63%

(n=330) after 2L and 13% (n=69) after 3L. Pts that became LEN Ref before 3L (87%) were less likely to receive triplet regimens on the LOT they became Ref vs non-LEN Ref (1L: 61% vs 82%, p< 0.0001; 2L: 56% vs 65%, p=0.0039). LEN Ref pts, compared to non-LEN Ref, had a longer mean [SD] duration of therapy (DoT) (1L: 14.1 vs 8.4 months, p< 0.0001; 2L: 17.74 vs 12.9, p< 0.0001) on the line they first became LEN Ref or were exposed to LEN (non-LEN Ref). After pts became LEN Ref, DoT (after 1L: 10.1 vs 15.1, p=0.0007; after 2L: 13.2 vs 13.9, p=0.544) and time to relapse (after 1L: 11.4 vs 18.4, p=0.0005; after 2L: 8.4 vs 11.0, p=0.0418) worsens compared to non-LEN Ref pts. **Conclusions:** This analysis shows most LEN Ref pts were exposed to a PI and IMiD, while also becoming refractory to LEN before they reach 3L. These LEN Ref pts had significantly faster progression and were less likely to receive treatment with triplets, showing shorter DoT and time to relapse compared to pts non-LEN Ref. There is an unmet need for new and effective tx for LEN-ref pts as early as the 2L.

Introduction: Teclistamab, the only approved BCMA×CD3 bispecific antibody with a personalized, weight-based, and flexible dosing schedule for the treatment (tx) of triple-class exposed (TCE) relapsed/refractory multiple myeloma (RRMM), has shown promising efficacy in the phase 1/2 MajesTEC-1 study (NCT03145181/NCT04557098). As MajesTEC-1 is a single-arm study, we assessed the comparative effectiveness of teclistamab vs real-world physician's choice of therapy (RWPC) in pts with TCE RRMM from the real-world, prospective, noninterventional studies, LocoMMotion (NCT04035226; enrolled Aug 2019–Oct 2020; clinical cut-off [CCO] Oct 27, 2022) and MoMMent (NCT05160584; enrolled Nov 2021–July 2022; CCO Oct 27, 2022). MoMMent was initiated as a complement to LocoMMotion to assess practice changes in recent years. **Methods:** Pts treated with the recommended phase 2 dose of teclistamab (1.5 mg/kg tx doses) from MajesTEC-1 (N=165; CCO Jan 4, 2023) were compared with an external control arm from LocoMMotion alone (N=248) or from pooled LocoMMotion + MoMMent (N=302). Inverse probability of tx weighting estimating the average tx effect in the treated population was used to adjust for imbalances in baseline covariates of prognostic significance: refractory status, ISS stage, time to progression on prior line of therapy [LOT], extramedullary disease, number of prior LOTs, time since diagnosis, average duration of prior LOTs, age, hemoglobin, lactate dehydrogenase, creatinine clearance, ECOG performance status, gender, MM type, and prior transplant. Relative effect of teclistamab vs RWPC for rates of overall response (ORR), very good partial response or better (≥VGPR), and complete response or better (≥CR) was estimated with an odds ratio using weighted logistic regression transformed into a response-rate ratio (RR) and 95% CI. A weighted Cox proportional hazards model was used to estimate hazard ratios (HRs) and 95% CIs for duration of response (DOR), progression-free survival (PFS), and overall survival (OS). **Results:** Baseline characteristics were well balanced between the 3 cohorts after reweighting external control arms. Pts treated with teclistamab had significantly improved outcomes vs RWPC in LocoMMotion: ORR (RR [95% CI], 2.32 [1.71–3.15]; P< 0.0001), ≥VGPR (RR, 5.60 [3.64–8.62]; P< 0.0001), ≥CR (RR, 183.80 [14.89–2268.30]; P< 0.0001), DOR (HR, 0.35 [0.21–0.56]; P< 0.0001), PFS (HR, 0.47 [0.35–0.64]; P< 0.0001), and OS (HR, 0.64 [0.47–0.88]; P=0.0051). Teclistamab vs RWPC in LocoMMotion + MoMMent also had significantly improved outcomes: ORR (RR [95% CI], 2.38 [1.78–3.19]; P< 0.0001), ≥VGPR (RR, 6.02 [4.00–9.08]; P< 0.0001), ≥CR (RR, 178.55 [18.88–1688.40]; P< 0.0001), DOR (HR, 0.38 [0.23–0.63]; P=0.0002), PFS (HR, 0.48 [0.35–0.65]; P< 0.0001), and OS (HR, 0.67 [0.49–0.91]; P=0.0117). **Conclusions:** Teclistamab demonstrated significantly improved effectiveness over RWPC in LocoMMotion alone and pooled LocoMMotion + MoMMent, emphasizing its clinical benefit as a highly effective tx for pts with TCE RRMM.

(n=330) after 2L and 13% (n=69) after 3L. Pts that became LEN Ref before 3L (87%) were less likely to receive triplet regimens on the LOT they became Ref vs non-LEN Ref (1L: 61% vs 82%, p< 0.0001; 2L: 56% vs 65%, p=0.0039). LEN Ref pts, compared to non-LEN Ref, had a longer mean [SD] duration of therapy (DoT) (1L: 14.1 vs 8.4 months, p< 0.0001; 2L: 17.74 vs 12.9, p< 0.0001) on the line they first became LEN Ref or were exposed to LEN (non-LEN Ref). After pts became LEN Ref, DoT (after 1L: 10.1 vs 15.1, p=0.0007; after 2L: 13.2 vs 13.9, p=0.544) and time to relapse (after 1L: 11.4 vs 18.4, p=0.0005; after 2L: 8.4 vs 11.0, p=0.0418) worsens compared to non-LEN Ref pts. **Conclusions:** This analysis shows most LEN Ref pts were exposed to a PI and IMiD, while also becoming refractory to LEN before they reach 3L. These LEN Ref pts had significantly faster progression and were less likely to receive treatment with triplets, showing shorter DoT and time to relapse compared to pts non-LEN Ref. There is an unmet need for new and effective tx for LEN-ref pts as early as the 2L.

Efficacy, survival and safety of selinexor, bortezomib and dexamethasone (SVd) in patients with lenalidomide-refractory multiple myeloma: subgroup data from the BOSTON trial

María-Victoria Mateos[1], Monika Engelhardt[2], Xavier Leleu[3], Mercedes Gironella Mesa[4], Michele Cavo[5], Meletios Dimopoulos[6], Martina Bianco[7], Giovanni Marino Merlo[7], Charles La Porte[7], Philippe Moreau[8]

[1]University Hospital of Salamanca/IBSAL/CIC/CIBERONC, Salamanca, Spain; [2]Interdisciplinary Cancer Center, University of Freiburg; [3]Hospital La Mileterie, Poitiers, France; [4]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [5]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "Seràgnoli", Università degli Studi di Bologna, Bologna, Italy; [6]National and Kapodistrian University of Athens; [7]Stemline Therapeutics/Menarini Group; [8]University Hospital Hôtel-Dieu, Nantes, France

Introduction: Lenalidomide (LEN) is commonly used in frontline therapy for newly diagnosed MM, and there is a need for effective treatment options for patients (pts) with MM refractory to LEN. Selinexor is a first-in-class, oral XPO1 inhibitor with a unique mechanism of action. SVd is indicated in adults with relapsed and refractory MM (RRMM) who have received at least one prior therapy. Initial results of the BOSTON phase 3 trial demonstrated significant improvements in median progression-free survival (mPFS) and overall response rate (ORR) with SVd vs bortezomib and dexamethasone (Vd) in previously treated MM (Grosicki et al. Lancet 2020). We analyzed data from the phase 3 BOSTON trial (NCT03110562) to determine the impact of refractoriness to LEN on SVd efficacy (both PFS and overall survival [OS]) and safety. **Methods:** Eligible pts with RRMM and 1-3 prior therapies were randomized to SVd (selinexor 100 mg QW, bortezomib 1.3 mg/m^2 QW and dexamethasone 20 mg BIW) or standard Vd BIW. We performed a post-hoc stratified analysis of PFS, OS (with crossover adjustment using the two-stage method), response rates and safety in subgroups by refractory status to LEN. **Results:** Of 402 pts, 106 were classified as LEN-refractory (SVd=53, Vd=53). Sixteen pts (30.2%) in the SVd arm became LEN-refractory after 1 prior line of therapy (LOT) and 69.8% after 2 or more LOT; in the Vd group 26.4% became LEN-refractory after 1 prior LOT; 73.6% after 2 or more LOT. Median age was 65 ys (range 40-87) in the SVd arm and 66 y (range 45-85) in the Vd arm. At the time of the analyses, median follow-up was 28.7 mo for SVd arm and 28.6 mo for Vd arm. mPFS was 10.2 mo (95% CI 5.8-NR) with SVd vs 7.1 mo (95% CI 3.5-9.8) with Vd (HR 0.52; 95% CI 0.31-0.88, p=0.012). mOS was 26.7 mo (95% CI 19.9-NR) with SVd vs 18.6 mo (95% CI 13.9-29.0) with Vd, resulting in a statistically significant and clinically meaningful improvement in OS (HR 0.53; 95% CI 0.30-0.95, p=0.03). Response rates for SVd and Vd were as follows: ORR 67.9% vs 47.2% and VGPR or better 35.8% vs 24.5%, respectively. The most common (≥25%) treatment-emergent adverse events with SVd vs Vd in 105 LEN-refractory pts included in the safety population were thrombocytopenia (71.7% vs 40.4%), nausea (50.9% vs 11.5%), fatigue (45.3% vs 21.1%), diarrhea (43.4% vs 19.2%), anemia (39.6% vs 25.0%), and peripheral neuropathy (30.2% vs 38.5%). **Conclusions:** Subgroup data from the BOSTON trial show a statistically significant and clinically meaningful improvement in OS and PFS and higher ORR and VGPR or better with SVd vs Vd in LEN-refractory RRMM pts. The safety profile in the subgroups was similar to that observed in the overall BOSTON population. The statistically significant 47% reduction in risk of death with SVd vs Vd shows an advantage of having a regimen built on two drugs with different mechanisms of action in the difficult-to-treat population of LEN-refractory RRMM pts.

Introduction: Melphalan flufenamide (melflufen), a first-in-class peptide-drug conjugate (PDC), and dexamethasone (dex) is approved in Europe for use in patients (pts) with ≥3 prior lines of therapy (LoTs) and triple-class refractory RRMM (time to progression [TTP] >36 mo if pt had a prior autologous stem cell transplant [ASCT]). Results from the phase 2 HORIZON and phase 3 OCEAN studies supported the approval. Melflufen + daratumumab + dex (Dd) showed clinical activity and manageable safety in the

phase 1/2 ANCHOR study (Ocio EM, et al. ASH 2020, abstract 417), and was further assessed in the phase 3 LIGHTHOUSE study (NCT04649060). **Methods:** Pts with RRMM, refractory to an IMiD and a proteasome inhibitor (PI) or with ≥3 prior LoTs including an IMiD and a PI, were randomized (1:1) to 28-day cycles (C) of intravenous melflufen (30 mg on day 1 per cycle) + oral dex (40 mg weekly; 20 mg if aged ≥75 y) + subcutaneous Dara (1800 mg on days 1, 8, 15, and 22 in C1-2, day 1 and 15 in C3-6, and day 1 in C7+) or Dara monotherapy (regimen as in the melflufen arm) until disease progression or unacceptable toxicity. Prior anti-CD38 monoclonal antibody therapy was allowed, but no pts had received it. Pts with confirmed disease progression in the Dara arm could cross over to melflufen + Dd. Primary endpoint: progression-free survival (PFS). Key secondary endpoints: overall response rate (ORR) and safety. Financial considerations after a partial clinical hold issued by the FDA for all melflufen studies led to premature study closure (23 Feb 2022; data cutoff date). **Results:** From 21 Dec 2020 to 7 Jul 2021, 54 of 240 planned pts were randomized (melflufen + Dd, n=27; Dara, n=27); 2 pts crossed over to melflufen + Dd. With melflufen + Dd vs Dara, median age was 65 y vs 68 y, 11 (41%) vs 13 (48%) had no prior ASCT, and 3 (11%) vs 2 (7%) had a TTP >36 mo after a prior ASCT, respectively. Median PFS was not reached (NR) with melflufen + Dd vs 4.9 mo with Dara (hazard ratio [HR], 0.18 [95% CI, 0.05-0.65]; P=0.0032). ORR was 59.3% with melflufen + Dd vs 29.6% with Dara (P=0.0300). OS was immature, with 2 events with melflufen + Dd vs 4 events with Dara (HR, 0.47 [95% CI, 0.09-2.57]; P=0.3721). Among pts with no prior ASCT or with a TTP >36 mo after a prior ASCT (melflufen + Dd, n=14; Dara, n=15), median PFS was NR with melflufen + Dd (1 event) vs 3.9 mo with Dara (11 events; HR, 0.06 [95% CI, 0.01-0.49]; P=0.0005), ORR was 64.3% vs 13.3% (P=0.0055), and 1 vs 4 OS events occurred (P=0.0369), respectively. With melflufen + Dd vs Dara, the most common grade ≥3 treatment-emergent adverse events were neutropenia (50% vs 12%), thrombocytopenia (50% vs 8%), and anemia (32% vs 19%), respectively. **Conclusions:** Melflufen + Dd showed superior PFS and ORR vs Dara, including in pts with no prior ASCT or with a TTP >36 mo after a prior ASCT, which resembles the population with confirmed benefit from OCEAN. The safety profile of melflufen + Dd was consistent with previous reports of melflufen.

Selinexor, bortezomib, and dexamethasone in patients with previously treated multiple myeloma: updated results of BOSTON trial by prior therapies

María-Victoria Mateos[1], Monika Engelhardt[2], Xavier Leleu[3], Mercedes Gironella Mesa[4], Michele Cavo[5], Meletios Dimopoulos[6], Martina Bianco[7], Giovanni Marino Merlo[7], Charles La Porte[7], Philippe Moreau[8]

[1]University Hospital of Salamanca/IBSAL/CIC/CIBERONC, Salamanca, Spain; [2]Interdisciplinary Cancer Center, University of Freiburg; [3]Hospital La Mileterie, Poitiers, France; [4]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [5]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "Seràgnoli", Università degli Studi di Bologna, Bologna, Italy; [6]National and Kapodistrian University of Athens; [7]Stemline Therapeutics/Menarini Group; [8]University Hospital Hôtel-Dieu, Nantes, France

Introduction: Increasing use of daratumumab + lenalidomide + dexamethasone (DRd) in the frontline setting for multiple myeloma (MM) has led to more patients (pts) with proteasome inhibitor (PI)-naïve early relapse. ESMO Guidelines endorse a PI-based combination including selinexor, bortezomib, and dexamethasone (SVd) in MM pts with PI-naïve early relapse. Selinexor is a first-in-class, oral XPO1 inhibitor with a unique mechanism of action. SVd is indicated for relapsed and refractory MM (RRMM) in adults who have received at least one prior therapy. We analyzed longer follow-up data from the phase 3 BOSTON trial (NCT03110562) to determine the impact of prior therapies, including PI, on SVd efficacy and safety. **Methods:** Eligible pts with RRMM and 1-3 prior therapies were randomized to selinexor QW (100 mg), bortezomib QW (1.3 mg/m^2) and dexamethasone BIW (20 mg) (Vd) or standard BIW Vd. A stratified efficacy analysis and safety analysis were performed in subgroups by prior PI therapy and number of prior regimens. Efficacy analyses were based on Feb 2021 data cut and safety analyses on Jun 2022 data cut. **Results:** Of 402 pts, 198 received 1 prior line of treatment (LOT) (SVd=99; Vd=99; median ages 67 and 69 y, respectively); 95 were PI-naïve (SVd=47; Vd=48; median ages 68 and 67.5 y, respectively); 123 were bortezomib naïve (SVd=61; Vd=62; median ages 68 y both arms). In pts with 1 prior LOT, mPFS was 21.0 vs 10.7 months for SVD vs Vd (HR 0.62; 95% CI 0.41-0.95, p=0.028). In PI naïve pts mPFS was 29.5 vs 9.7 months for SVd vs Vd (HR 0.29; 95% CI 0.14-0.63, p< 0.001). In bortezomib naïve pts mPFS was 29.5 vs 9.7 months for SVd vs Vd (HR 0.35; 95% CI 0.18-0.68, p=0.002). Overall response rates (ORR) were higher with SVd vs Vd in all subgroups: 1 prior LOT 80.8% vs 66.7%; PI-naïve 76.6% vs 70.8%; bortezomib-naïve ORR 75.4% vs 69.4%. Most common (≥25%) treatment-emergent adverse events (AEs) with SVd vs Vd in pts with 1 prior LOT were thrombocytopenia (61.6% vs 28.6%), nausea (52.5% vs 11.2%), fatigue (45.4% vs 17.3%), peripheral neuropathy (38.4% vs 52.0%), diarrhea (34.3% vs 24.5%), and anemia (30.3% vs 26.5%). Safety findings were similar in the PI naïve and bortezomib naïve subgroups. **Conclusions:** Stratified subgroup data from longer follow-up in the BOSTON trial confirm the PFS benefit of SVd over Vd in pts without prior PI or bortezomib exposure as well as pts who have received 1 prior LOT. There was a statistically significant and clinically meaningful ~20 mo median PFS improvement of SVd over Vd in RRMM pts that had no prior exposure to PI and bortezomib, as well as a significant ~10 mo PFS improvement in pts with 1 prior LOT. These outcomes coupled with generally manageable AE profile emphasize the synergy between selinexor and bortezomib and the importance of a double mode of action switch, further supporting SVd use in 1) PI-naïve RRMM pts, 2) bortezomib-naïve RRMM pts, and 3) pts at first relapse.

phase 1/2 ANCHOR study (Ocio EM, et al. ASH 2020, abstract 417), and was further assessed in the phase 3 LIGHTHOUSE study (NCT04649060). **Methods:** Pts with RRMM, refractory to an IMiD and a proteasome inhibitor (PI) or with ≥3 prior LoTs including an IMiD and a PI, were randomized (1:1) to 28-day cycles (C) of intravenous melflufen (30 mg on day 1 per cycle) + oral dex (40 mg weekly; 20 mg if aged ≥75 y) + subcutaneous Dara (1800 mg on days 1, 8, 15, and 22 in C1-2, day 1 and 15 in C3-6, and day 1 in C7+) or Dara monotherapy (regimen as in the melflufen arm) until disease progression or unacceptable toxicity. Prior anti-CD38 monoclonal antibody therapy was allowed, but no pts had received it. Pts with confirmed disease progression in the Dara arm could cross over to melflufen + Dd. Primary endpoint: progression-free survival (PFS). Key secondary endpoints: overall response rate (ORR) and safety. Financial considerations after a partial clinical hold issued by the FDA for all melflufen studies led to premature study closure (23 Feb 2022; data cutoff date). **Results:** From 21 Dec 2020 to 7 Jul 2021, 54 of 240 planned pts were randomized (melflufen + Dd, n=27; Dara, n=27); 2 pts crossed over to melflufen + Dd. With melflufen + Dd vs Dara, median age was 65 y vs 68 y, 11 (41%) vs 13 (48%) had no prior ASCT, and 3 (11%) vs 2 (7%) had a TTP >36 mo after a prior ASCT, respectively. Median PFS was not reached (NR) with melflufen + Dd vs 4.9 mo with Dara (hazard ratio [HR], 0.18 [95% CI, 0.05-0.65]; P=0.0032). ORR was 59.3% with melflufen + Dd vs 29.6% with Dara (P=0.0300). OS was immature, with 2 events with melflufen + Dd vs 4 events with Dara (HR, 0.47 [95% CI, 0.09-2.57]; P=0.3721). Among pts with no prior ASCT or with a TTP >36 mo after a prior ASCT (melflufen + Dd, n=14; Dara, n=15), median PFS was NR with melflufen + Dd (1 event) vs 3.9 mo with Dara (11 events; HR, 0.06 [95% CI, 0.01-0.49]; P=0.0005), ORR was 64.3% vs 13.3% (P=0.0055), and 1 vs 4 OS events occurred (P=0.0369), respectively. With melflufen + Dd vs Dara, the most common grade ≥3 treatment-emergent adverse events were neutropenia (50% vs 12%), thrombocytopenia (50% vs 8%), and anemia (32% vs 19%), respectively. **Conclusions:** Melflufen + Dd showed superior PFS and ORR vs Dara, including in pts with no prior ASCT or with a TTP >36 mo after a prior ASCT, which resembles the population with confirmed benefit from OCEAN. The safety profile of melflufen + Dd was consistent with previous reports of melflufen.

Retrospective study of treatment patterns and clinical outcomes by race in patients with triple-class-exposed multiple myeloma treated in a real-world setting

Aster Meche[1], Felix Rondeau[2], Samy Gallienne[2], Patrick Hlavacek[1], Jinma Ren[1], Karen Repetny[1], Sarasa Johnson[2], Alexander Schepart[1], Marco DiBonaventura[1]

[1]Pfizer Inc; [2]Statlog

Introduction: Disparities in access to treatment and clinical outcomes are experienced by multiple myeloma (MM) patients from different racial groups. The objective of this study was to describe differences in treatment patterns and clinical outcomes of real-world (RW) triple-class-exposed (TCE) MM patients (i.e., exposed to ≥1 PI, ≥1 IMiD, ≥1 anti-CD38) by race. **Methods:** Data from two US electronic health record databases (COTA and Flatiron Health) were pooled with duplicate patients removed for this analysis. TCE MM patients initiating a subsequent line of therapy (LOT) (i.e., index LOT) following documentation of exposure to all three classes of drug, who were ≥18 years, and had race information captured within these databases were identified. Patients were categorized as White, Black, Asian, or Other race. Patient and disease characteristics, treatment history and patterns, and clinical outcomes (i.e., response, progression, treatment switch, and death) were described for each racial group using descriptive statistics. Progression-free survival (PFS), time to next treatment (TTNT), and overall survival (OS) were calculated using Kaplan-Meier methods. **Results:** A total of 1,383 patients were identified (White 1,010 (73%); Black 213 (15%); Asian 36 (3%); Other 124 (9%)). Patient characteristics were similar though Other patients were more likely to identify as Hispanic (41% vs 2-8%, p<.05) and the distribution of some comorbidities also differed (e.g., renal disease: White 10%, Black 17%, Asian 14%, Other 14%, p<.05). Disease characteristics and treatment history were also comparable regardless of race, including exposure to different treatments (e.g., stem cell transplant 47-53%, p=.38) and time from MM diagnosis to index LOT (36.3-41.5 median (m) months, p=.62). However, a significantly higher proportion of Asian patients had the t(4;14) cytogenetic marker (25% vs 8-11%, p<.05). Treatments received in the index LOT were comparable, though White patients were more likely to receive an investigational agent (5% vs 0-2%, p<.05) and Asian patients were more likely to receive treatment combinations including carfilzomib (50% vs 27-31%, p<.05). Response rates did not differ significantly based on race (White 27%, Black 27%, Asian 44%, Other 30%, p=.15). Time-to-event outcome results (months) were as follows: mPFS - White 9.9, Black 8.3, Asian 15.9, Other 12.7; mTTNT – White 7.6, Black 8.9, Asian 10.9, Other 7.8; mOS – White 21.1, Black 17.4, Asian 37.5, Other 27.4. **Conclusions:** No clear health disparity trends were observed among TCE MM patients based on race. This suggests that when patients have equal access to treatment options, differences in outcomes are not necessarily observed. Known health disparities by race may therefore arise earlier in a patient's journey. As such, research exploring if certain race groups are less likely to reach TCE status, while considering other barriers, is needed.

Survival outcomes in older patients with relapsed/refractory multiple myeloma treated with either IMiD- or non-IMiD-based regimens after triple-class exposure in the PREAMBLE registry

Philippe Moreau[1], Ravi Vij[2], Hartmut Goldschmidt[3], David Kuter[4], David Cella[5], Sujith Dhanasiri[6], Jin Gu[7], Jiaqi Fang[7], Thomas Marshall[7], Susan Fish[7], Karthik Ramasamy[8]

[1]University Hospital Hôtel-Dieu, Nantes, France; [2]Division of Oncology, Washington University School of Medicine, St Louis, MO, USA; [3]Internal Medicine V, GMMG Study Group at University Hospital Heidelberg, Heidelberg, Germany; [4]Center for Hematology, Massachusetts General Hospital, Boston, MA, USA; [5]Northwestern University Feinberg School of Medicine, Chicago, IL, USA; [6]Celgene International Sàrl, a Bristol-Myers Squibb Company, Boudry, Switzerland; [7]Bristol Myers Squibb, Princeton, NJ, USA; [8]Oxford University Hospitals NHS Foundation Trust, Oxford, UK

Introduction: A significant proportion of patients with multiple myeloma (MM) eventually relapse or become refractory to treatment. Age is an independent prognostic factor in MM, but there is limited information on real-world treatment patterns and clinical outcomes in older patients with relapsed/refractory MM (RRMM) who have been exposed to three prior therapy classes (triple-class exposed [TCE]). The aim of this analysis was to describe the patient characteristics and outcomes (progression-free survival [PFS] and overall survival [OS]) in older patients with TCE RRMM treated with immunomodulatory agents (IMiDs) or non-IMiD agents in the real-world setting. **Methods:** Prospectively collected data were extracted from the multicenter Prospective REsearch Assessment in Multiple Myeloma: An oBservational Evaluation (PREAMBLE) registry, which enrolled patients with newly diagnosed MM and RRMM in Europe and the US from 2012 to 2020. Included patients were ≥70 years of age, TCE (previously treated with an IMiD [lenalidomide (Rev), pomalidomide (Pom), thalidomide (Tha)], an anti-CD38 antibody, and a proteasome inhibitor [PI]), and started a subsequent IMiD (Rev/Pom) or non-IMiD (non-Rev/Pom/Tha) line of therapy at their physician's discretion. All analyses were descriptive; Kaplan-Meier curves were used for PFS and OS analyses. Index date was the date of initiation of post-TCE IMiD or non-IMiD therapy. **Results:** Among 190 TCE patients who initiated a subsequent line of therapy, 91 patients were ≥70 years of age (median age 75 years). At index, 43 of these patients (47.3%) received an IMiD regimen and 48 (52.7%) received a non-IMiD regimen. Baseline demographics were broadly similar between groups. A high proportion of patients were previously refractory to IMiDs in both the IMiD and non-IMiD groups (36/43 [83.7%] and 43/48 [89.6%], respectively). In the IMiD group, the index treatments were: retreatment with IMiD only (14.0%), IMiD+PI (14.0%), IMiD + anti-CD38 (30.2%), and IMiD + other (41.9%). In the non-IMiD group, the index treatments were: PI only (33.3%), anti-CD38 containing regimens (25.0%), and other (41.7%). A total of 19 (44.2%) IMiD-treated patients received a subsequent line of therapy after index compared with 23 (47.9%) non-IMiD treated patients. Overall, the median

Introduction: A significant proportion of patients with multiple myeloma (MM) eventually relapse or become refractory to treatment. Age is an independent prognostic factor in MM, but there is limited information on real-world treatment patterns and clinical outcomes in older patients with relapsed/refractory MM (RRMM) who have been exposed to three prior therapy classes (triple-class exposed [TCE]). The aim of this analysis was to describe the patient characteristics and outcomes (progression-free survival [PFS] and overall survival [OS]) in older patients with TCE RRMM treated with immunomodulatory agents (IMiDs) or non-IMiD agents in the real-world setting. **Methods:** Prospectively collected data were extracted from the multicenter Prospective REsearch Assessment in Multiple Myeloma: An oBservational Evaluation (PREAMBLE) registry, which enrolled patients with newly diagnosed MM and RRMM in Europe and the US from 2012 to 2020. Included patients were ≥70 years of age, TCE (previously treated with an IMiD [lenalidomide (Rev), pomalidomide (Pom), thalidomide (Tha)], an anti-CD38 antibody, and a proteasome inhibitor [PI]), and started a subsequent IMiD (Rev/Pom) or non-IMiD (non-Rev/Pom/Tha) line of therapy at their physician's discretion. All analyses were descriptive; Kaplan-Meier curves were used for PFS and OS analyses. Index date was the date of initiation of post-TCE IMiD or non-IMiD therapy. **Results:** Among 190 TCE patients who initiated a subsequent line of therapy, 91 patients were ≥70 years of age (median age 75 years). At index, 43 of these patients (47.3%) received an IMiD regimen and 48 (52.7%) received a non-IMiD regimen. Baseline demographics were broadly similar between groups. A high proportion of patients were previously refractory to IMiDs in both the IMiD and non-IMiD groups (36/43 [83.7%] and 43/48 [89.6%], respectively). In the IMiD group, the index treatments were: retreatment with IMiD only (14.0%), IMiD+PI (14.0%), IMiD + anti-CD38 (30.2%), and IMiD + other (41.9%). In the non-IMiD group, the index treatments were: PI only (33.3%), anti-CD38 containing regimens (25.0%), and other (41.7%). A total of 19 (44.2%) IMiD-treated patients received a subsequent line of therapy after index compared with 23 (47.9%) non-IMiD treated patients. Overall, the median

(95% CI) PFS in this group of patients aged ≥70 years was 5.2 (3.0–8.3) months, with 5.9 (2.9–9.3) months in IMiD-treated patients compared with 4.6 (2.3–8.3) months in non-IMiD treated patients. The overall median (95% CI) OS was 19.7 (13.0–NA) months – 16.0 (8.7–NA) in IMiD-treated patients compared with 19.7 (13.0–NA) in non-IMiD treated patients. **Conclusions:** In this study of an older population with TCE RRMM, subsequent treatment regimens were heterogeneous. Survival outcomes appeared to be similar with IMiD- and non-IMiD–based regimens. As this was a relatively small and descriptive study, future analyses are required to further elucidate these findings.

Introduction: In about half of the MM patients, genetic defects and/or abnormal expression are observed in epigenetic modifiers (epiplayers) at the time of diagnosis and this further increases at relapse, indicating an important role for epiplayers in MM cell drug resistance (DR). However, so far, only for two epiplayers, MMSET and EZH2, a clear role in MM cell DR has been formally established. Using RNASeq data from the MMRF CoMMpass study, we found that the epiplayer DNMT3B is significantly increased in the relapsed setting, suggesting a role in MM relapse. Here, we explored the role of DNMT3B in MM cell biology and drug response. **Methods:** Both the DNMT3B specific inhibitor Nanaomycin A (NA) and genetic knockdown using a doxycycline inducible shRNA against DNMT3B (shDNMT3B) were used to specifically target DNMT3B. RNA sequencing was performed upon genetic knockdown in AMO-1 (high DNMT3B levels) and XG-2 (intermediate DNMT3B levels) human myeloma cell lines (HMCL). Viability and apoptosis were assessed using a CellTiter-Glo assay and AnnexinV/7AAD stainings. Cell proliferation was measured by BrdU incorporation and cell cycle analysis, while the clonogenic capacity was evaluated by a colony formation assay. **Results:** Here, we report that high DNMT3B mRNA expression correlates with a worse disease outcome in both newly diagnosed and relapsed patients, indicating a role for DNMT3B in MM progression and DR. Targeting DNMT3B in HMCL using either shDNMT3B or NA resulted in a strong and significant increase in cell death. NA treatment also strongly reduced viability of primary human MM cells, while human BMSC were much less affected. RNA sequencing identified 794 genes differentially expressed upon DNMT3B depletion, with 394 genes upregulated and 400 genes downregulated in DNMT3B-depleted cells compared to non-depleted cells (Fold change > 1.5; FDR ≤ 0.05). Gene set enrichment analysis (GSEA) of the upregulated genes identified significant enrichment of genes involved in histone methylation and stem cells, whereas downregulated genes are mainly involved in cell cycle, apoptosis, stem cells and MM proliferating molecular subgroup. In line, cell cycle analysis upon DNMT3B silencing and NA treatment revealed impaired cell proliferation due to an arrest in the G1 phase. In addition, a strong and significant reduction in the number of colonies was observed upon DNMT3B targeting, thus supporting a role for DNMT3B in MM cell clonogenicity and thus potentially also in MM stemness. Importantly, combining NA with either Bortezomib (Bz) or Melphalan (Mel) resulted in a synergistic inhibition of MM cell viability and further increase in the anti-clonogenic activity. Furthermore, NA was also able to resensitize both Mel and Bz resistant XG-2 cells. **Conclusions:** Together, our findings provide for the first time evidence that DNMT3B could be a novel promising epigenetic target to overcome or delay relapse in MM.

Introduction: BCMA is a promising therapeutic target in multiple myeloma, as it is an antigen expressed specifically on plasma cells, with a higher expression in myeloma cells. The aim of this study was to assess the effectiveness and tolerability of monotherapy with the conjugated anti-BCMA monoclonal antibody belantamab mafodotin in triple-class refractory MM patients in the real-world practice. **Methods:** The patients were administered belantamab mafodotin at 2.5 mg/kg intravenously once every 3 weeks. The drug is indicated as monotherapy for the treatment of multiple myeloma in adult patients, who have received at least four prior therapies and whose disease is refractory to at least one PI, one IMiD, and an anti-CD38 monoclonal antibody, and who have demonstrated disease progression on the last therapy. **Results:** Overall, 27 patients were included in this analysis. Regarding the previous lines of treatment, all patients had received lenalidomide, bortezomib and anti-CD38 treatment, whereas 70% had received pomalidomide, and 89% had received carfilzomib. 59% of the patients had LDH above normal limits at the time of the initiation of the treatment. The patients had a median age of 65 years old (range 41-81), 52% were male and the median number of prior lines of treatment was 5 (4-10). 19% of the patients were ISS 3 and 14% RISS 3 at diagnosis. One

(95% CI) PFS in this group of patients aged ≥70 years was 5.2 (3.0–8.3) months, with 5.9 (2.9–9.3) months in IMiD-treated patients compared with 4.6 (2.3–8.3) months in non-IMiD treated patients. The overall median (95% CI) OS was 19.7 (13.0–NA) months – 16.0 (8.7–NA) in IMiD-treated patients compared with 19.7 (13.0–NA) in non-IMiD treated patients. **Conclusions:** In this study of an older population with TCE RRMM, subsequent treatment regimens were heterogeneous. Survival outcomes appeared to be similar with IMiD- and non-IMiD–based regimens. As this was a relatively small and descriptive study, future analyses are required to further elucidate these findings.

Introduction: BCMA is a promising therapeutic target in multiple myeloma, as it is an antigen expressed specifically on plasma cells, with a higher expression in myeloma cells. The aim of this study was to assess the effectiveness and tolerability of monotherapy with the conjugated anti-BCMA monoclonal antibody belantamab mafodotin in triple-class refractory MM patients in the real-world practice. **Methods:** The patients were administered belantamab mafodotin at 2.5 mg/kg intravenously once every 3 weeks. The drug is indicated as monotherapy for the treatment of multiple myeloma in adult patients, who have received at least four prior therapies and whose disease is refractory to at least one PI, one IMiD, and an anti-CD38 monoclonal antibody, and who have demonstrated disease progression on the last therapy. **Results:** Overall, 27 patients were included in this analysis. Regarding the previous lines of treatment, all patients had received lenalidomide, bortezomib and anti-CD38 treatment, whereas 70% had received pomalidomide, and 89% had received carfilzomib. 59% of the patients had LDH above normal limits at the time of the initiation of the treatment. The patients had a median age of 65 years old (range 41-81), 52% were male and the median number of prior lines of treatment was 5 (4-10). 19% of the patients were ISS 3 and 14% RISS 3 at diagnosis. One

patient is still receiving therapy, whereas the median number of lines post treatment with belantamab mafodotin is 1 (range 0-8) and 26% of patients are currently alive. The ORR (overall response rate, PR or better) in this cohort was 52%, whereas the DCR (disease control rate, SD or better) was 89%. The median PFS for the entire group was 2 months (95%CI: 0-7), whereas the median PFS among the responders was 12 months (95%CI: 6-18). Interestingly, the median PFS was 10 months (95%CI: 0-22) for patients who started belantamab mafodotin due to biochemical relapse, as compared to a median PFS of only 0.9 months (95%CI: 0.5-1.2) for patients with symptomatic myeloma relapse. The median OS was 89 months (95%CI: 48-129) from MM diagnosis, whereas the landmark median OS was 16 months (95%CI: 2-30) from belantamab mafodotin initiation. The landmark median OS for the responders was 40 months (95%CI: 24-56). Regarding the toxicity profile, the most common toxicity was eye toxicity in 44% of the patients. More specifically, keratopathy grade 2-3 was reported in 33.3% of the patients. Keratopathy was resolved in all patients, however one patient had to discontinue treatment due to corneal ulcer. Reduction in visual acuity was reported in 26% of the patients. Other toxicities included infections gr 2-3 in five patients, thrombocytopenia gr 3 in two patients and fatigue gr 2 in four patients. **Conclusions:** Belantamab mafodotin showed a safety and efficacy profile consistent with the results of the DREAMM-2 study in triple-class refractory patients with MM in terms of survival benefit and tolerability in the real-world practice.

Introduction: Melphalan flufenamide (melflufen), a first-in-class peptide-drug conjugate (PDC), plus dexamethasone (dex) is approved for use in Europe in patients (pts) with triple-class refractory RRMM who have received ≥3 prior lines of therapy (LoTs) and progressed >36 mo after a prior autologous stem cell transplant if received. Here, we report the final data for the phase 1/2a ANCHOR study of melflufen with bortezomib + dex (Vd) or daratumumab + dex (Dd) (NCT03481556). **Methods:** Pts had RRMM refractory/intolerant to an IMiD and/or a proteasome inhibitor (PI) and 1-4 prior LoTs. Vd arm: PI in prior LoT (but not refractoriness in the last LoT) was allowed. Dd arm: prior anti-CD38 monoclonal antibody therapy prohibited. All pts received intravenous (IV) melflufen (30 or 40 mg, day 1 per cycle). Vd arm: bortezomib 1.3 mg/m^2 subcutaneous, days 1, 4, 8, and 11 + oral dex (20 mg on days 1, 4, 8, and 11 and 40 mg on days 15 and 22; dose reduced if aged ≥75 y). Dd arm: daratumumab 16 mg/kg IV once per wk (2 cycles), every 2 wk (4 cycles), then every 4 wk + oral dex (40 mg on days 1, 8, 15, and 22). Primary objectives: determine the optimal melflufen dose in each combination (phase 1); assess overall response rate (ORR; phase 2). **Results:** As of 9 Feb 2022 (data cutoff date), 23 pts received melflufen (30 mg, n=15; 40 mg, n=8) +Vd and 33 melflufen (30 mg, n=6; 40 mg, n=27) +Dd. The partial clinical hold issued by the US Food and Drug Administration led to premature study termination on 23 Feb 2022. Vd arm: Median (range) treatment duration was 8.3 mo (2.8-40.0) in the 30-mg cohort and 12.0 mo (2.1-34.7) in the 40-mg cohort. ORR for the pooled cohorts was 78% (2 complete response or better [≥CR], 5 very good partial response [VGPR], 11 partial response [PR]). At a median follow-up of 21 mo, the median progression-free survival (PFS) was 14.7 mo (95% CI, 8.5-33.5); overall survival (OS) was immature with 17 pts (74%) alive at data cutoff. Grade ≥3 treatment-emergent adverse events (TEAEs) were most commonly cytopenias and infrequently nonhematologic; thrombocytopenia led to treatment discontinuation in 3 pts. No dose-limiting toxicities (DLTs) and 3 fatal AEs (1 cardiac failure chronic, 2 COVID-19 pneumonia) occurred. Dd arm: Median (range) treatment duration was 24.1 mo (0.9-44.6) in the 30-mg cohort and 6.2 mo (0.9-41.2) in the 40-mg cohort. ORR was 73% (3 ≥CR, 8 VGPR, 13 PR). Median (95% CI) PFS was 12.9 mo (7.7-15.4) and OS was 26.1 mo (16.4-not estimable), at a median follow-up of 30.0 and 32.8 mo, respectively. Thrombocytopenia and neutropenia were the most common grade ≥3 TEAEs and TEAEs leading to treatment discontinuation. Grade ≥3 nonhematologic TEAEs were infrequent. No DLTs and 4 fatal AEs (2 sepsis, 1 cardiac failure chronic, 1 general physical health deterioration) occurred. **Conclusions:** Melflufen + Vd or Dd showed encouraging activity in RRMM with 1-4 prior LoTs. Safety and efficacy analyses determined melflufen 30 mg to be the recommended dose in triplet regimens.

patient is still receiving therapy, whereas the median number of lines post treatment with belantamab mafodotin is 1 (range 0-8) and 26% of patients are currently alive. The ORR (overall response rate, PR or better) in this cohort was 52%, whereas the DCR (disease control rate, SD or better) was 89%. The median PFS for the entire group was 2 months (95%CI: 0-7), whereas the median PFS among the responders was 12 months (95%CI: 6-18). Interestingly, the median PFS was 10 months (95%CI: 0-22) for patients who started belantamab mafodotin due to biochemical relapse, as compared to a median PFS of only 0.9 months (95%CI: 0.5-1.2) for patients with symptomatic myeloma relapse. Introduction: Melphalan flufenamide (melflufen), a first-in-class peptide-drug conjugate (PDC), plus dexamethasone (dex) is approved for use in Europe in patients (pts) with triple-class refractory RRMM who have received ≥3 prior lines of therapy (LoTs) and progressed >36 mo after a prior autologous stem cell transplant if received. Here, we report the final data for the phase 1/2a ANCHOR study of melflufen with bortezomib + dex (Vd) or daratumumab + dex (Dd) (NCT03481556). **Methods:** Pts had RRMM refractory/intolerant to an IMiD and/or a proteasome inhibitor (PI) and 1-4 prior LoTs. Vd arm: PI in prior LoT (but not refractoriness in the last LoT) was allowed. Dd arm: prior anti-CD38 monoclonal antibody therapy prohibited. All pts received intravenous (IV) melflufen (30 or 40 mg, day 1 per cycle). Vd arm: bortezomib 1.3 mg/m^2 subcutaneous, days 1, 4, 8, and 11 + oral dex (20 mg on days 1, 4, 8, and 11 and 40 mg on days 15 and 22; dose reduced if aged ≥75 y). Dd arm: daratumumab 16 mg/kg IV once per wk (2 cycles), every 2 wk (4 cycles), then every 4 wk + oral dex (40 mg on days 1, 8, 15, and 22). Primary objectives: determine the optimal melflufen dose in each combination (phase 1); assess overall response rate (ORR; phase 2). **Results:** As of 9 Feb 2022 (data cutoff date), 23 pts received melflufen (30 mg, n=15; 40 mg, n=8) +Vd and 33 melflufen (30 mg, n=6; 40 mg, n=27) +Dd. The partial clinical hold issued by the US Food and Drug Administration led to premature study termination on 23 Feb 2022. Vd arm: Median (range) treatment duration was 8.3 mo (2.8-40.0) in the 30-mg cohort and 12.0 mo (2.1-34.7) in the 40-mg cohort. ORR for the pooled cohorts was 78% (2 complete response or better [≥CR], 5 very good partial response [VGPR], 11 partial response [PR]). At a median follow-up of 21 mo, the median progression-free survival (PFS) was 14.7 mo (95% CI, 8.5-33.5); overall survival (OS) was immature with 17 pts (74%) alive at data cutoff. Grade ≥3 treatment-emergent adverse events (TEAEs) were most commonly cytopenias and infrequently nonhematologic; thrombocytopenia led to treatment discontinuation in 3 pts. No dose-limiting toxicities (DLTs) and 3 fatal AEs (1 cardiac failure chronic, 2 COVID-19 pneumonia) occurred. Dd arm: Median (range) treatment duration was 24.1 mo (0.9-44.6) in the 30-mg cohort and 6.2 mo (0.9-41.2) in the 40-mg cohort. ORR was 73% (3 ≥CR, 8 VGPR, 13 PR). Median (95% CI) PFS was 12.9 mo (7.7-15.4) and OS was 26.1 mo (16.4-not estimable), at a median follow-up of 30.0 and 32.8 mo, respectively. Thrombocytopenia and neutropenia were the most common grade ≥3 TEAEs and TEAEs leading to treatment discontinuation. Grade ≥3 nonhematologic TEAEs were infrequent. No DLTs and 4 fatal AEs (2 sepsis, 1 cardiac failure chronic, 1 general physical health deterioration) occurred. **Conclusions:** Melflufen + Vd or Dd showed encouraging activity in RRMM with 1-4 prior LoTs. Safety and efficacy analyses determined melflufen 30 mg to be the recommended dose in triplet regimens.

Introduction: Recent therapeutic advances in multiple myeloma (MM) patients have dramatically improved patients' outcomes. But drug resistance is an emerging challenge resulting in a poor survival with the urgent need for effective therapies, mostly in triple-refractory MM. Belantamab mafodotin (belamaf), the first-in-class antibody-drug conjugate (ADC) targeting B-cell maturation antigen (BCMA), demonstrated efficacy in monotherapy in DREAMM-2 trial and was approved for relapsed/refractory MM (rrMM) patients with at least four previous lines of therapy (LOT). **Methods:** Being belamaf real-world data scarce, we designed a retro-prospective study aiming to evaluate its efficacy and safety in rrMM patients treated in compassionate use programmes as Named Patient Program (NPP) and Expanded Access Program (EAP) in Italy, under the aegis of European Myeloma Network (EMN). The primary endpoint was the rate of patients achieving a clinical benefit (at least minimal response according to IMWG criteria). Secondary endpoints were safety, ORR (at least PR), duration of response (DoR), progression-free survival (PFS) and overall survival (OS). Eligible criteria were: ≥18 years of age, MM diagnosis according to IMWG criteria, triple-refractoriness (at least one PI, one IMID and one anti-CD38 mAb) and at least 4 prior LOTs. **Results:** Overall, 67 patients have been enrolled by 18 Italian centers, with a median age of 66 years (range 42-82), a median of 6 prior LOT (4-10), ECOG 65, p=0.094 and ECOG≥2, p=0.012 **Conclusions:** In conclusion, our cohort had fewer previous LOTs but similar median age than DREAMM-2 population. We found similar ORR, OS and safety profile, but median PFS and DOR seem to be longer. PFS seems to be not affected by classical disease prognostic factors but by baseline patient characteristics.

Introduction: The prognosis of triple class refractory (TCR) multiple myeloma (MM) patients is dismal, mainly due to the lack of rescue therapies. Newer immunotherapy approaches such us chimeric antigen receptor T (CAR-T) cells and bispecific monoclonal antibodies (BiAbs) directed against BCMA, GPRC5D or FcRH5 have been effective in the TCR setting. However, there are not studies that compared the effectiveness of CAR-T and BiAbs, as well as which is the prognosis of patients who relapsed to these treatments. **Methods:** An observational retrospective study was conducted to indirectly compare the efficacy of CAR-T and BiAbs in 68 TCR patients treated within clinical trials between December 2018 and February 2023. **Results:** Sixty-eight patients were included in this study, 31 were treated with CAR-T and 37 with BiABs (directed against BCMA in 23, GPRC5D in 11 and FcRH5 in 3 patients). No differences were observed except that the BiAbs group had higher proportion of patients >65 years, with more extramedullary disease at relapse and more pretreated compared to the CAR-T group. The overall rate response (at least partial response) was significantly better in the CAR-T group than the BiAbs group (odds ratio 22.1 [95% confidence interval (CI), 2.7-179.9]; P=0.004). In addition, patients treated with CAR-T reached more frequently complete response or better (66.7% vs. 43.2%; P=0,056). After a median of follow-up

Introduction: The prognosis of triple class refractory (TCR) multiple myeloma (MM) patients is dismal, mainly due to the lack of rescue therapies. Newer immunotherapy approaches such us chimeric antigen receptor T (CAR-T) cells and bispecific monoclonal antibodies (BiAbs) directed against BCMA, GPRC5D or FcRH5 have been effective in the TCR setting. However, there are not studies that compared the effectiveness of CAR-T and BiAbs, as well as which is the prognosis of patients who relapsed to these treatments. **Methods:** An observational retrospective study was conducted to indirectly compare the efficacy of CAR-T and BiAbs in 68 TCR patients treated within clinical trials between December 2018 and February 2023. **Results:** Sixty-eight patients were included in this study, 31 were treated with CAR-T and 37 with BiABs (directed against BCMA in 23, GPRC5D in 11 and FcRH5 in 3 patients). No differences were observed except that the BiAbs group had higher proportion of patients >65 years, with more extramedullary disease at relapse and more pretreated compared to the CAR-T group. The overall rate response (at least partial response) was significantly better in the CAR-T group than the BiAbs group (odds ratio 22.1 [95% confidence interval (CI), 2.7-179.9]; P=0.004). In addition, patients treated with CAR-T reached more frequently complete response or better (66.7% vs. 43.2%; P=0,056). After a median of follow-up

of 14.6 months (m) (interquartile range, 3,7-54,1), no differences in the progression-free survival (PFS) were observed between the CAR-T and the BiAbs groups (14.1 vs. 12,1 m; P=0.110), but patients receiving CAR-T achieved longer overall survival (OS) (43.0 vs. 18.2 m, hazard ratio 2.3 [95% CI, 1.1-5.2]; P=0.050). Thirty-two patients (12 in the CAR-T and 20 in the BiAbs group) were rescued after progression. Overall, these rescue therapies were very heterogeneous, but 66.7% of the CAR-T group and 25% of the BiAbs group were treated with BiAbs in the subsequent treatment. Patients treated with BiAbs at relapsed showed a trend toward better response. Patients in the CAR-T group who were treated with BiAbs (with a different target than the BCMA) presented the longest PFS 2 (29.1 m), significantly more prolonged than patients in this group rescued with other schemes, (7,9 m, P< 0.001), as well as patients of the BiAbs group regardless of the treatment used at relapse (BiAbs: 7,3 m, P< 0.001; and other therapies: 8.4 m, P=0.002). **Conclusions:** The present study showed that CAR-T and BiAbs are effective treatment in TCR MM patients. In this scenario, CAR-T resulted in better responses, but no differences were observed in PFS compared to BiAbs. However, patients of the CAR-T group presented superior OS showing the importance of treatment sequence and how BiAbs could be useful after CAR-T to improve survival in TCR patients. The identification of sequence approach as well as the development of novel drugs represent the new unmet medical need in the relapse of patients TCR after the new immunotherapy.

DREAMM-20: a study to investigate the safety and efficacy of belantamab for the treatment of multiple myeloma (MM) when used as monotherapy and in combination treatments

Hang Quach[1], Shang-Yi Huang[2], Hsuan-Yu Lin[3], Dok Hyun Yoon[4], Giulia Fulci[5], Nirav Ratia[5], John Clements[5], Eric Lewis[5], Wei Sun[5], Malika Ahras[5], Sarantos Kaptanis[5], Seema Shafi-Harji[5], Brandon Kremer[5], Chang-Ki Min[6]

[1]St Vincent's Hospital Melbourne, University of Melbourne, VIC, Australia; [2]National Taiwan University Hospital, Taipei; [3]Changhua Christian Hospital; [4]Asan Medical Center, University of Ulsan College of Medicine; [5]GSK; [6]Seoul St. Mary's Hospital, Seoul, South Korea

Introduction: MM is an incurable malignant clonal plasma cell disorder and accounts for 1% of all cancers and 10% of all hematologic malignancies. Treatments include combinations of proteasome inhibitors (PIs), immunomodulatory drugs, monoclonal antibodies, alkylating agents, and corticosteroids as well as the newer chimeric antigen receptor T-cell therapies, antibody-drug conjugates (ADCs), and bispecific antibodies. As relapse usually occurs, there is a high unmet need for effective treatments with better safety profiles, given the toxicity of current and emerging treatments. B-cell maturation antigen (BCMA), a cell surface receptor, is upregulated on MM cells. Belantamab (GSK2857914) is a humanized afucosylated immunoglobulin G1 monoclonal antibody targeting BCMA. Belantamab shares the same antibody structure as the ADC belantamab mafodotin but without the conjugated monomethyl auristatin-F payload. Based on preclinical data, belantamab mediates antibody-dependent cellular cytotoxicity through increased FcγRIII binding and antibody-dependent cellular phagocytosis, and blocks BCMA-activated prosurvival and proliferative signaling. Preclinical evidence supports clinical investigation of belantamab for MM. **Methods:** Part 1 of DREAMM-20 is a phase 1/2, open-label, multicenter, dose-escalation study of patients with relapsed or refractory MM to determine the safety, tolerability, and recommended part 2 dose for belantamab. Inclusion criteria include patients aged ≥18 years with confirmed MM (defined by the International Myeloma Working Group [IMWG]), measurable disease, Eastern Cooperative Oncology Group performance status of 0 to 2, and adequate organ system function. Patients must have received ≥3 prior lines of therapy, which included an immunomodulatory agent, a PI, and an anti-CD38 antibody (unless contraindicated or unavailable). Prior receipt of BCMA-targeted agents is allowed. Key exclusion criteria include current corneal epithelial disease except nonconfluent superficial punctate keratitis, meningeal or central nervous system involvement with MM, uncontrolled hypertension, and evidence of clinically significant untreated arrhythmias. Patients will receive belantamab via intravenous infusion on days 1 and 15 of 28-day cycles. Dose escalation is conducted using the modified toxicity probability interval method. The primary endpoint is the incidence of adverse events, including dose-limiting toxicities, which will be assessed using National Cancer Institute Common Terminology Criteria for Adverse Events v5.0. Secondary endpoints include pharmacokinetics, incidence of antidrug antibodies, and overall response rate (assessed per the 2016 IMWG criteria). Exploratory endpoints include quality of life, pharmacodynamics (including longitudinal soluble BCMA and M-protein levels), and other biomarker assessments. The trial is sponsored by GSK and registered at ClinicalTrials.gov (NCT05714839).

of 14.6 months (m) (interquartile range, 3,7-54,1), no differences in the progression-free survival (PFS) were observed between the CAR-T and the BiAbs groups (14.1 vs. 12,1 m; P=0.110), but patients receiving CAR-T achieved longer overall survival (OS) (43.0 vs. 18.2 m, hazard ratio 2.3 [95% CI, 1.1-5.2]; P=0.050). Thirty-two patients (12 in the CAR-T and 20 in the BiAbs group) were rescued after progression. Overall, these rescue therapies were very heterogeneous, but 66.7% of the CAR-T group and 25% of the BiAbs group were treated with BiAbs in the subsequent treatment. Patients treated with BiAbs at relapsed showed a trend toward better response. Patients in the CAR-T group who were treated with BiAbs (with a different target than the BCMA) presented the longest PFS 2 (29.1 m), significantly more prolonged than patients in this group rescued with other schemes, (7,9 m, P< 0.001), as well as patients of the BiAbs group regardless of the treatment used at relapse (BiAbs: 7,3 m, P< 0.001; and other therapies: 8.4 m, P=0.002). **Conclusions:** The present study showed that CAR-T and BiAbs are effective treatment in TCR MM patients. In this scenario, CAR-T resulted in better responses, but no differences were observed in PFS compared to BiAbs. However, patients of the CAR-T group presented superior OS showing the importance of treatment sequence and how BiAbs could be useful after CAR-T to improve survival in TCR patients. The identification of sequence approach as well as the development of novel drugs represent the new unmet medical need in the relapse of patients TCR after the new immunotherapy.

DREAMM-20: a study to investigate the safety and efficacy of belantamab for the treatment of multiple myeloma (MM) when used as monotherapy and in combination treatments

Hang Quach[1], Shang-Yi Huang[2], Hsuan-Yu Lin[3], Dok Hyun Yoon[4], Giulia Fulci[5], Nirav Ratia[5], John Clements[5], Eric Lewis[5], Wei Sun[5], Malika Ahras[5], Sarantos Kaptanis[5], Seema Shafi-Harji[5], Brandon Kremer[5], Chang-Ki Min[6]

[1]St Vincent's Hospital Melbourne, University of Melbourne, VIC, Australia; [2]National Taiwan University Hospital, Taipei; [3]Changhua Christian Hospital; [4]Asan Medical Center, University of Ulsan College of Medicine; [5]GSK; [6]Seoul St. Mary's Hospital, Seoul, South Korea

Introduction: MM is an incurable malignant clonal plasma cell disorder and accounts for 1% of all cancers and 10% of all hematologic malignancies. Treatments include combinations of proteasome inhibitors (PIs), immunomodulatory drugs, monoclonal antibodies, alkylating agents, and corticosteroids as well as the newer chimeric antigen receptor T-cell therapies, antibody-drug conjugates (ADCs), and bispecific antibodies. As relapse usually occurs, there is a high unmet need for effective treatments with better safety profiles, given the toxicity of current and emerging treatments. B-cell maturation antigen (BCMA), a cell surface receptor, is upregulated on MM cells. Belantamab (GSK2857914) is a humanized afucosylated immunoglobulin G1 monoclonal antibody targeting BCMA. Belantamab shares the same antibody structure as the ADC belantamab mafodotin but without the conjugated monomethyl auristatin-F payload. Based on preclinical data, belantamab mediates antibody-dependent cellular cytotoxicity through increased FcγRIII binding and antibody-dependent cellular phagocytosis, and blocks BCMA-activated prosurvival and proliferative signaling. Preclinical evidence supports clinical investigation of belantamab for MM. **Methods:** Part 1 of DREAMM-20 is a phase 1/2, open-label, multicenter, dose-escalation study of patients with relapsed or refractory MM to determine the safety, tolerability, and recommended part 2 dose for belantamab. Inclusion criteria include patients aged ≥18 years with confirmed MM (defined by the International Myeloma Working Group [IMWG]), measurable disease, Eastern Cooperative Oncology Group performance status of 0 to 2, and adequate organ system function. Patients must have received ≥3 prior lines of therapy, which included an immunomodulatory agent, a PI, and an anti-CD38 antibody (unless contraindicated or unavailable). Prior receipt of BCMA-targeted agents is allowed. Key exclusion criteria include current corneal epithelial disease except nonconfluent superficial punctate keratitis, meningeal or central nervous system involvement with MM, uncontrolled hypertension, and evidence of clinically significant untreated arrhythmias. Patients will receive belantamab via intravenous infusion on days 1 and 15 of 28-day cycles. Dose escalation is conducted using the modified toxicity probability interval method. The primary endpoint is the incidence of adverse events, including dose-limiting toxicities, which will be assessed using National Cancer Institute Common Terminology Criteria for Adverse Events v5.0. Secondary endpoints include pharmacokinetics, incidence of antidrug antibodies, and overall response rate (assessed per the 2016 IMWG criteria). Exploratory endpoints include quality of life, pharmacodynamics (including longitudinal soluble BCMA and M-protein levels), and other biomarker assessments. The trial is sponsored by GSK and registered at ClinicalTrials.gov (NCT05714839).

Final results of a Phase 1b study of subcutaneous isatuximab administration by an on-body delivery system (OBDS) plus pomalidomide and dexamethasone in relapsed/refractory multiple myeloma (RRMM)

Hang Quach[1], Gurdeep Parmar[2], Enrique Ocio[3], H. Miles Prince[4], Albert Oriol[5], Nobuhiro Tsukada[6], Kazutaka Sunami[7], Pierre Bories[8], Sumit Madan[9], Dorothee Semiond[10], Disa Yu[10], Sandrine Macé[11], Florence Suzan[11], Philippe Moreau[12]

[1]St Vincent's Hospital Melbourne, University of Melbourne, VIC, Australia; [2]Illawarra Cancer Care Centre Wollongong, NSW, Australia; [3]Hospital Universitario Marqués de Valdecilla (IDIVAL), Santander, Spain; [4]Peter MacCallum Cancer Centre; [5]Catalan Institute of Oncology and Josep Carreras Institute, Hospital Germans Trias i Pujol, Badalona, Spain; [6]Japanese Red Cross Medical Center, Tokyo, Japan; [7]National Hospital Organization Okayama Medical Center, Okayama, Japan; [8]Institut Universitaire du Cancer Toulouse, Toulouse, France; [9]Banner MD Anderson Cancer Center, Gilbert, AZ; [10]Sanofi, Cambridge, MA; [11]Sanofi, Vitry-sur-Seine, France; [12]University Hospital Hôtel-Dieu, Nantes, France

Introduction: Intravenous (IV) administration of isatuximab (Isa) plus pomalidomide-dexamethasone (Pd) is approved for patients (pts) with RRMM. Subcutaneous (SC) delivery allows a shorter duration of administration, with the aim to optimize convenience of administration and enhance patient comfort. Prior investigations in a Phase 1b study (NCT04045795) determined the recommended phase 2 dose (RP2D) for SC Isa at 1400 mg, and showed safety and efficacy for SC Isa + Pd comparable to IV Isa + Pd in the pivotal ICARIA-MM trial in RRMM pts. We now present the final safety and efficacy study results. **Methods:** This multicenter Phase 1b study evaluated SC vs IV Isa + Pd in RRMM pts with ≥2 prior treatment lines including lenalidomide and a proteasome inhibitor. Pts were randomized to SC by infusion pump (IP)1000 mg or IV 10 mg/kg and to IP1400 mg or IV. In the expansion cohort, SC Isa was administered at the RP2D via OBDS, a wearable bolus injector applied to the abdomen by a healthcare professional. Safety and PK were the primary endpoints; the main secondary endpoints were overall response rate (ORR) and progression-free survival (PFS). **Results:** Of the 56 randomized pts, 25% (3/12) IV, 25% (3/12) IP1000, 30% (3/10) IP1400 and 32% (7/22) of OBDS pts remained on treatment as of 15 Apr 2023. Median follow-up was 33 mo for IV, 39 mo for IP1000, 33 mo for IP1400 and 19 mo for the OBDS cohort due to the sequential accrual. ≥50% of pts had received ≥3 prior treatment lines. In the IV, IP1000, IP1400 and OBDS cohorts, serious treatment-related AEs occurred in 17%, 25%, 50% and 14% of pts; any ≥G3 infections were reported in 25%, 25%, 30% and 36% of pts including 0%, 8%, 0% and 14% ≥G3 Covid-19, respectively. Median duration of OBDS injections was 10 min (6.6-49.5); all injections were completed successfully with no interruption and no infusion reactions (IRs). Local tolerability was good: 7 (32%) pts had 10 injection site reactions, all G1, in 581 administrations (1.7%), mainly erythemas. The relative dose intensity of Isa at the SC RP2D was ≥90% (97%, 95%, 91% and 93% in the IV, IP1000, IP1400 and OBDS cohorts, respectively). ORR was 66.7% in the IV, 66.7% in the IP1000, 80% in the IP1400, and 72.7% in the OBDS cohorts (75% at the RP2D). Median PFS was 22.0 mo, 17.4 mo, not reached and 20.6 mo, respectively (20.6 mo at the RP2D). Minimal residual disease negativity (by NGS) at 10-5 sensitivity was achieved by 1/12 (8%) IV, 0/12 IP1000, 2/10 (20%) IP1400 and 2/22 (9%) OBDS pts (4 CR, 1 VGPR pts) (13% at the RP2D). The incidence of anti-drug antibodies appeared comparable after administration of Isa SC or IV (9.1% vs 8.3%). **Conclusions:** Final study results with SC Isa administration via OBDS at the 1400 mg RP2D + Pd show an efficacy and safety profile consistent with IV administration, with no IRs, and excellent local tolerability. A non-inferiority Phase 3 trial (NCT05405166) evaluating SC Isa via OBDS versus IV Isa is ongoing.

Efficacy and safety of elranatamab monotherapy in patients with relapsed/refractory multiple myeloma: a post-hoc subgroup analysis from MagnetisMM-3 with modified eligibility criteria

Marc Raab[1], Salomon Manier[2], H. Miles Prince[3], Ajay Nooka[4], Rayan Kaedbey[5], Jens Hillengass[6], Tadao Ishida[7], Sharon Sullivan[8], Umberto Conte[8], Eric Leip[8], Andrea Viqueira[9], Noopur Raje[10]

[1]Dept. of Medicine V Hematology, Oncology and Rheumatology, University Hospital Heidelberg, Heidelberg, Germany; [2]Centre Hospitalier Universitaire de Lille, Université de Lille, Lille, France; [3]Peter MacCallum Cancer Centre; [4]Winship Cancer Institute, Emory University School of Medicine; [5]McGill University; [6]Roswell Park Comprehensive Cancer Center; [7]Japanese Red Cross Medical Center, Tokyo, Japan; [8]Pfizer inc; [9]Pfizer SLU, Madrid, Spain; [10]Massachusetts General Hospital, Boston, MA, USA

Introduction: Results from the Phase 2 MagnetisMM-3 trial (NCT04649359) demonstrated elranatamab (BCMA x CD3 bispecific monoclonal antibody [bsAb]) monotherapy as an effective treatment for patients (pts) with RRMM with a manageable safety profile. Eligibility criteria in MagnetisMM-3 were sufficiently broad to allow for the enrollment of a representative real-world pt population. Here, we present a subgroup analysis of MagnetisMM-3 with modified eligibility criteria reflective of the pt population enrolled in other recent clinical trials of BCMA-directed bsAb. **Methods:** The following modified inclusion/exclusion criteria were applied to the pt population of MagnetisMM-3 Cohort A (BCMA-naïve): ECOG PS ≤1, no CNS involvement, no prior treatment with bi-specific antibodies, platelets ≥75,000 (or ≥50,000 if ≥50% bone marrow plasma cell involvement), eGFR ≥40 mL/min/1.73 m^2. All other eligibility criteria and analysis endpoints remained the same as previously reported (Bahlis et al., ASH 2022). Data cutoff was ~15 mo after last pt's initial dose. **Results:** With the modified criteria, 33 (26.8%) pts were excluded from the original analysis population of MagnetisMM-3 Cohort A. For the 90 pts meeting the modified eligibility criteria, median age was 69 y (range, 36–88), 52.2% were male; median number of prior lines of therapy was 4.0 (2–11); 97.8% and 38.9% of pts were triple-class- and penta-drug refractory, respectively. High-risk cytogenetics [t(4;14), t(14;16),or del(17p)] were present in 24.4% of pts, 27.8% of pts had extramedullary disease by BICR and 11.1% had an R-ISS of III at baseline. At data cutoff, the median follow-up was 15.1 mo (range, 0.2–25.1) and the median treatment duration was 8.4 mo (range, 0.03–24.4); 36.7% of pts remained on treatment. Most common reason for permanent treatment discontinuation was progressive disease (37.8%). Objective response rate per BICR was 67.8% (95% CI, 57.1, 77.2), with 38.9% CR or sCR, 24.4% VGPR, and 4.4% PR. Median duration of response (DOR) has not been reached (95% CI, NE–NE) and DOR rate at 15 mo was 67.1% (95% CI, 52.7, 78.0), median progression-free survival was 13.9 mo (95% CI, 9.8, NE). Most common Grade 3/4 treatment-emergent AEs were hematologic (75.6%), among these the most frequent (≥30%) were neutropenia (46.7%) and anemia (31.1%). Grade 3/4 infections were reported in 41.1% of pts, most common (≥10%) was COVID-19 pneumonia (13.3%); 5 (5.6%) pts had Grade 5 infections. CRS and ICANS occurred in 58.9% and 5.6% of pts respectively. There were no Grade ≥3 CRS or ICANS events. **Conclusions:** In this post-hoc subgroup analysis of pts with RRMM in MagnetisMM-3 with modified eligibility criteria that resemble recent clinical trials of BCMA-directed bsAb, elranatamab monotherapy remained efficacious with a manageable safety profile. Results were comparable

Introduction: Intravenous (IV) administration of isatuximab (Isa) plus pomalidomide-dexamethasone (Pd) is approved for patients (pts) with RRMM. Superiority of daratumumab plus lenalidomide and dexamethasone in first and second relapse in multiple myeloma patients: a real-world single centre retrospective analysis

Jolien Raddoux[1], Anneleen Vanhellemont[1], Michel Delforge[1]

[1]University Hospital Leuven, Leuven, Belgium

Introduction: The anti-CD38 antibody daratumumab is an important part of the treatment strategy in newly diagnosed and relapsed/refractory multiple myeloma (MM) patients. Data proving the benefit of daratumumab-based over non-daratumumab based regimens in the real-world setting are still limited. The aim of this real-world data analysis was to evaluate the clinical benefit of the use of daratumumab in 2nd and 3rd line treatment in a large cohort of anti-CD38 naïve patients with relapsed MM treated in the University Hospital Leuven, Belgium. **Methods:** Data from the UZ Leuven patient database were analysed through the Augmenting THerapeutic Effectiveness through Novel Analytics (ATHENA) platform. The UZ Leuven Multiple Myeloma database was transformed to the OMOP-Common Data Model 5.3.1 as part of the ATHENA project. Patient data were collected until April 12, 2022. Different cohorts were identified based on daratumumab or non-daratumumab treatment in 2nd line treatment (DARA-2 versus non-DARA-2) and 3rd line treatment (DARA-3 versus non-DARA-3). We analysed the time to next treatment and overall survival from 2nd line treatment (TTNT2; OS2) and from 3rd line treatment (TTNT3; OS3). **Results:** A total of 217 patients were included in this retrospective analysis. The cohorts contained respectively 107 patients in DARA-2, 39 patients in non-DARA-2, 39 patients in DARA-3 and 74 patients in non-DARA-3. In the DARA-2 cohort, 73 patients were treated with daratumumab-lenalidomide-dexamethasone (DRd) and 34 patients with daratumumab-bortezomib-dexamethasone (DVd). The median TTNT2 was 11,0 months in the DVd group versus not been reached (NR) in the DRd group (HR: 3,75; 95% CI: 2,1-6,68; p < 0,001). In the DVd group, median OS2 was 21, 8 months versus not been reached in the DRd group (HR: 2,99; 95%CI: 1,38-6,48; p=0,005). The median TTNT2 was significantly longer in the DRd group compared to the non-DARA-2 cohort (NR vs 20,5 months; HR: 0,44; 95% CI: 0,25-0,76; p=0,003). In the DARA-3 cohort, 29 patients were treated with DRd and 10 patients with DVd. The median TTNT3 was longer for the DRd group compared to the DVd group (20,7 vs 5,4 months; HR: 4,41; 95% CI 1,94-9,98; p< 0,001). The longest OS3 was also observed in the DRd group (41,9 months), compared to the DVd group (18,9 months) (HR: 2,82; 95% CI: 1,08-7,32; p=0,03). The median TTNT3 was significantly longer in the DRd group compared to the non-DARA-3 cohort (20,7 vs 5,8 months; HR: 0,49; 95% CI: 0,29-0,82; p=0,006). **Conclusions:** This single centre real-world data analysis shows the clinical benefit of dara-based over non-dara based regimens in first and second relapse. In addition, compared with DVd, DRd is associated with significantly longer TTNT and survival.

P-309

ZnDDC, a novel CELMoD-like agent binding to DDB1-CRBN complex demonstrates significant synergism with BTZ and IMiDs and overcomes IMiDs resistance in myeloma cell lines and primary samples

Gowtham Rajendran[1], Vinodh Kannappan[1], Karim Azar[1], Elyas Khan[2], Q. Ping Dou[2], Supratik Basu[1], Weiguang Wang[1]

[1]University of Wolverhampton; [2]Wayne State University

Introduction: Although immunomodulatory imide drugs (IMiDs), also called CRBN E3 ligase modulatory drugs (CELMoDs), e.g., lenalidamide (LEN), pomalidomide (POM) and proteasome inhibitor [bortezomib (BTZ)] improved the survival rate of multiple myeloma (MM), all MM patients are relapsed due to drug resistance. Therefore, development of new IMiDs is of clinical urgency. Due to the time (15 years) and costs (£1.5 billion/drug) for new drug development, repositioning of old drugs for new indications is an emerging economical strategy. Disulfiram (DS), an anti-alcoholism drug used in clinic for over 60 years, demonstrates excellent specific anticancer activity with no/low toxicity to normal tissues. DS chelates copper (Cu) and zinc (Zn) to form copper-diethyldithiocarbamate (CuDDC) and zinc-diethyldithiocarbamate (ZnDDC) which are the active anticancer compounds. Although the anticancer activity of DS has been known for more than three decades, its application in cancer clinic has been limited by its very short half-life in the bloodstream (< 4 min). In the recent years, we developed long half-life injectable DS showing strong anticancer efficacy in numerous cancer animal models. In this study, we developed a novel PEGylated liposome encapsulated ZnDDC (PEG-Lipo/ZnDDC) which shows stronger immunomodulatory and anti-MM effect than currently available IMiDs (LEN and POM) and reverses resistance, and synergistically enhances the anti-MM activity of IMiDs and BTZ. **Methods:** MTT assay, RT-PCR, Western blot, Fluorescence imaging, Flow cytometry, Magnetic bead primary MM cell isolation and culture, HPLC, isobologram analysis, Nano formulation techniques, computer docking and modelling. **Results:** We successfully developed PEG-Lipo/ZnDDC with satisfied drug loading content and controlled releasing. ZnDDC showed strong cytotoxicity in MM cell lines and patient-derived MM cells (IC50s: 5-10μM) in normoxic and hypoxic conditions. ZnDDC synergistically enhanced the cytotoxicity of IMiDs and BTZ and reversed their chemoresistance in normoxic and hypoxic conditions. Although ZnDDC had no effect on mRNA expression of cereblon (CRBN), IKZF1, IKZF3 and IRF4, a significant downregulation of IKZF1, IKZF3, IRF4 and cMyc proteins was observed after treating the MM cell lines with sub-cytotoxic concentrations of ZnDDC (2-5 μM). After exposure to low concentration of ZnDDC, levels of both IL-2 mRNA and protein were significantly boosted in T lymphocytes. Computer modelling through molecular docking using the AutoDock Vina software demonstrated a very strong

to those observed in the overall cohort confirming a clinical benefit in this subgroup as well as in the overall broader pt population.

Superiority of daratumumab plus lenalidomide and dexamethasone in first and second relapse in multiple myeloma patients: a real-world single centre retrospective analysis

Jolien Raddoux[1], Anneleen Vanhellemont[1], Michel Delforge[1]

[1]University Hospital Leuven, Leuven, Belgium

Introduction: The anti-CD38 antibody daratumumab is an important part of the treatment strategy in newly diagnosed and relapsed/refractory multiple myeloma (MM) patients. Data proving the benefit of daratumumab-based over non-daratumumab based regimens in the real-world setting are still limited. The aim of this real-world data analysis was to evaluate the clinical benefit of the use of daratumumab in 2nd and 3rd line treatment in a large cohort of anti-CD38 naïve patients with relapsed MM treated in the University Hospital Leuven, Belgium. **Methods:** Data from the UZ Leuven patient database were analysed through the Augmenting THerapeutic Effectiveness through Novel Analytics (ATHENA) platform. The UZ Leuven Multiple Myeloma database was transformed to the OMOP-Common Data Model 5.3.1 as part of the ATHENA project. Patient data were collected until April 12, 2022. Different cohorts were identified based on daratumumab or non-daratumumab treatment in 2nd line treatment (DARA-2 versus non-DARA-2) and 3rd line treatment (DARA-3 versus non-DARA-3). We analysed the time to next treatment and overall survival from 2nd line treatment (TTNT2; OS2) and from 3rd line treatment (TTNT3; OS3). **Results:** A total of 217 patients were included in this retrospective analysis. The cohorts contained respectively 107 patients in DARA-2, 39 patients in non-DARA-2, 39 patients in DARA-3 and 74 patients in non-DARA-3. In the DARA-2 cohort, 73 patients were treated with daratumumab-lenalidomide-dexamethasone (DRd) and 34 patients with daratumumab-bortezomib-dexamethasone (DVd). The median TTNT2 was 11,0 months in the DVd group versus not been reached (NR) in the DRd group (HR: 3,75; 95% CI: 2,1-6,68; p < 0,001). In the DVd group, median OS2 was 21, 8 months versus not been reached in the DRd group (HR: 2,99; 95%CI: 1,38-6,48; p=0,005). The median TTNT2 was significantly longer in the DRd group compared to the non-DARA-2 cohort (NR vs 20,5 months; HR: 0,44; 95% CI: 0,25-0,76; p=0,003). In the DARA-3 cohort, 29 patients were treated with DRd and 10 patients with DVd. The median TTNT3 was longer for the DRd group compared to the DVd group (20,7 vs 5,4 months; HR: 4,41; 95% CI 1,94-9,98; p< 0,001). The longest OS3 was also observed in the DRd group (41,9 months), compared to the DVd group (18,9 months) (HR: 2,82; 95% CI: 1,08-7,32; p=0,03). The median TTNT3 was significantly longer in the DRd group compared to the non-DARA-3 cohort (20,7 vs 5,8 months; HR: 0,49; 95% CI: 0,29-0,82; p=0,006). **Conclusions:** This single centre real-world data analysis shows the clinical benefit of dara-based over non-dara based regimens in first and second relapse. In addition, compared with DVd, DRd is associated with significantly longer TTNT and survival.

ZnDDC, a novel CELMoD-like agent binding to DDB1-CRBN complex demonstrates significant synergism with BTZ and IMiDs and overcomes IMiDs resistance in myeloma cell lines and primary samples

Gowtham Rajendran[1], Vinodh Kannappan[1], Karim Azar[1], Elyas Khan[2], Q. Ping Dou[2], Supratik Basu[1], Weiguang Wang[1]

[1]University of Wolverhampton; [2]Wayne State University

Introduction: Although immunomodulatory imide drugs (IMiDs), also called CRBN E3 ligase modulatory drugs (CELMoDs), e.g., lenalidamide (LEN), pomalidomide (POM) and proteasome inhibitor [bortezomib (BTZ)] improved the survival rate of multiple myeloma (MM), all MM patients are relapsed due to drug resistance. Therefore, development of new IMiDs is of clinical urgency. Due to the time (15 years) and costs (£1.5 billion/drug) for new drug development, repositioning of old drugs for new indications is an emerging economical strategy. Disulfiram (DS), an anti-alcoholism drug used in clinic for over 60 years, demonstrates excellent specific anticancer activity with no/low toxicity to normal tissues. DS chelates copper (Cu) and zinc (Zn) to form copper-diethyldithiocarbamate (CuDDC) and zinc-diethyldithiocarbamate (ZnDDC) which are the active anticancer compounds. Although the anticancer activity of DS has been known for more than three decades, its application in cancer clinic has been limited by its very short half-life in the bloodstream (< 4 min). In the recent years, we developed long half-life injectable DS showing strong anticancer efficacy in numerous cancer animal models. In this study, we developed a novel PEGylated liposome encapsulated ZnDDC (PEG-Lipo/ZnDDC) which shows stronger immunomodulatory and anti-MM effect than currently available IMiDs (LEN and POM) and reverses resistance, and synergistically enhances the anti-MM activity of IMiDs and BTZ. **Methods:** MTT assay, RT-PCR, Western blot, Fluorescence imaging, Flow cytometry, Magnetic bead primary MM cell isolation and culture, HPLC, isobologram analysis, Nano formulation techniques, computer docking and modelling. **Results:** We successfully developed PEG-Lipo/ZnDDC with satisfied drug loading content and controlled releasing. ZnDDC showed strong cytotoxicity in MM cell lines and patient-derived MM cells (IC50s: 5-10μM) in normoxic and hypoxic conditions. ZnDDC synergistically enhanced the cytotoxicity of IMiDs and BTZ and reversed their chemoresistance in normoxic and hypoxic conditions. Although ZnDDC had no effect on mRNA expression of cereblon (CRBN), IKZF1, IKZF3 and IRF4, a significant downregulation of IKZF1, IKZF3, IRF4 and cMyc proteins was observed after treating the MM cell lines with sub-cytotoxic concentrations of ZnDDC (2-5 μM). After exposure to low concentration of ZnDDC, levels of both IL-2 mRNA and protein were significantly boosted in T lymphocytes. Computer modelling through molecular docking using the AutoDock Vina software demonstrated a very strong

to those observed in the overall cohort confirming a clinical benefit in this subgroup as well as in the overall broader pt population.

Treatment preferences among triple-class exposed patients with relapsed/refractory multiple myeloma in the United States (US), United Kingdom (UK), and Germany (DE): a discrete choice experiment

Paula Rodríguez-Otero[1], Christine Michaels-Igbokwe[2], Hannah Collacott[3], Julia Braverman[4], Thomas Marshall[4], Antoine Tinel[5], Devender Dhanda[4]

[1]Clínica Universidad de Navarra, CIMA, CIBERONC, IDISNA, Pamplona, Spain; [2]Evidera, Montréal, QC, Canada; [3]Evidera, Bethesda, MD, USA; [4]Bristol Myers Squibb, Princeton, NJ, USA; [5]Celgene International Sàrl, a Bristol-Myers Squibb Company, Boudry, Switzerland

Introduction: Front line therapies for multiple myeloma (MM) comprise 3 treatment classes: immunomodulators, proteasome inhibitors, and anti-CD38 antibodies. Few treatment options are available for patients who relapse or are refractory to all 3 classes (triple-class exposed [TCE]), and prognoses are poor. Chimeric antigen receptor (CAR) T cell therapies offer new options for treating TCE patients with relapsed/refractory MM (RRMM). However, patient preferences for CAR T therapy attributes are poorly understood. This study aimed to quantify preferences for attributes relating to standard multi-cycle treatments and CAR T therapy in patients with TCE RRMM. **Methods:** An online survey and best–best discrete choice experiment (BB-DCE), was developed based on clinical trial interviews, a literature review, and clinical expertise. The BB-DCE included 6 treatment attributes: 2-year overall survival (OS), median progression-free survival (PFS), bone pain, risk of severe cytokine release syndrome (sCRS), risk of any mild-to-moderate chronic side effects, and dosing schedule reflecting two multi-cycle (oral and subcutaneous or intravenous) and one single-cycle options. Each of the 9 choice tasks consisted of 3 treatment profiles; attribute levels presented in 2 profiles varied according to an experimental design, and 1 fixed profile aligned with a standard multi-cycle treatment. Patients selected the most preferred profile out of 3, then the most preferred from the remaining 2. Adults (≥18 years of age) with self-reported TCE RRMM were eligible to complete the survey. Choice data were analyzed using standard regression models (mixed logit) to estimate preference weights. Relative attribute importance (RAI) scores were calculated, and attribute trade-offs were estimated using a valuation space model with OS as numéraire. **Results:** A total of 170 TCE patients (UK: n=30, US: n=87, DE: n=53) completed the BB-DCE. Mean age was 63 years; 51.8% (n=88) were male. At the time of the study, most patients were receiving MM treatment (n=121). Across attributes, changes in 2-year OS had the largest influence on treatment preferences (24.9%), followed by PFS (24.5%), chronic side effects (17.6%), bone pain (16.5%), and dosing schedule (10.3%), and risk of sCRS (6.2%). All else being equal, patients preferred single-cycle over multi-cycle treatment (oral or SC/IV. OS and PFS were both 4 times more important than the risk of sCRS. The additional value that patients placed on a treatment offering a 12-month increase in PFS (from 3 to 15 months) was equivalent to the value of a 51% increase in OS. Patients valued shifting from a multi-cycle IV or SC treatment to a single-cycle treatment as equivalent to a 23% increase in 2-year OS. **Conclusions:** Patients' preferences for RRMM treatments were driven by survival outcomes. All else being equal, the value that patients place on a single-cycle treatment such as CAR T cell therapy is likely to outweigh up to a 10% risk of sCRS.

Survival of patients with relapsed/refractory multiple myeloma receiving palliative therapy with cyclophosphamide/ prednisone: results in 346 patients from a single institution over the last 50 years

Laura Rosinol[1], Carlos Fernández de Larrea[2], Maria Teresa Cibeira[1], Luis Gerardo Rodríguez-Lobato[1], Natalia Tovar[1], David Moreno[1], Joan Bladé[1]

[1]Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain; [2]Amyloidosis and Myeloma Unit, Department of Hematology, Hospital Clínic of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), University of Barcelona, Barcelona, Spain

Introduction: The overall survival (OS) of patients with multiple myeloma (MM) has significantly improved in recent years thanks to the introduction of new drugs. However, MM remains an incurable disease and patients continue to die from refractory myeloma. When the patient has exhausted all available therapeutic options, palliative treatment with cyclophosphamide and prednisone (CP) is common in some centers but there is no real life data on the survival of this population. **Methods:** From july 1972 to december 2021, 346 patients (48% men, median age 71 years) received palliative treatment with CP (cyclophosphamide 650 mg/m^2 i.v. every 3 or 4 weeks and alternate day prednisone at a dose of 30 mg po) as the last line of treatment. The time point when patients started CP therapy was considered the time zero (T0). From T0, three time periods were defined (1972-1999: N=108; 2000-2010: N=95; 2011-2021: N=143) based on the incorpotarion of novel classes of antimyeloma agents. **Results:** The median number of prior lines before T0 was 2 (1-4), 2 (1-8) and 3 (1-12) for periods 1, 2 and 3, respectively. In period 1, 81% of patients started CP after 1 or 2 prior lines compared with 54% and 47% of patients in periods 2 and 3, respectively. Thus, in period 1 only 3 patients (2,7%) received 4 prior lines, while in period 2 and 3, 23% and 38% of patients received ≥4 prior lines of therapy. The median time from diagnosis to T0 were significantly longer in period 3 (22, 33 and 43 months, p< 0.0001 for period 1, 2 and 3, respectively). The median OS from T0 in the overall series was 7 months and there was no difference

binding of ZnDDC to the DDB1-CRBN complex, similar to that of LEN and POM. ZnDDC also reversed hypoxia-induced IMiDs and BTZ resistance in tested MM cell lines. **Conclusions:** ZnDDC demonstrates CELMoD like property with synergistic effect when used in combination with clinically available IMiDs and BTZ; The effect of ZnDDC is potentially CRL4CRBN-IKZF1/3-IRF4 pathway dependent; Further study is ongoing which could translate this work into MM clinic in a fast track.

Introduction: The overall survival (OS) of patients with multiple myeloma (MM) has significantly improved in recent years thanks to the introduction of new drugs. However, MM remains an incurable disease and patients continue to die from refractory myeloma. When the patient has exhausted all available therapeutic options, palliative treatment with cyclophosphamide and prednisone (CP) is common in some centers but there is no real life data on the survival of this population. **Methods:** From july 1972 to december 2021, 346 patients (48% men, median age 71 years) received palliative treatment with CP (cyclophosphamide 650 mg/m^2 i.v. every 3 or 4 weeks and alternate day prednisone at a dose of 30 mg po) as the last line of treatment. The time point when patients started CP therapy was considered the time zero (T0). From T0, three time periods were defined (1972-1999: N=108; 2000-2010: N=95; 2011-2021: N=143) based on the incorpotarion of novel classes of antimyeloma agents. **Results:** The median number of prior lines before T0 was 2 (1-4), 2 (1-8) and 3 (1-12) for periods 1, 2 and 3, respectively. In period 1, 81% of patients started CP after 1 or 2 prior lines compared with 54% and 47% of patients in periods 2 and 3, respectively. Thus, in period 1 only 3 patients (2,7%) received 4 prior lines, while in period 2 and 3, 23% and 38% of patients received ≥4 prior lines of therapy. The median time from diagnosis to T0 were significantly longer in period 3 (22, 33 and 43 months, p< 0.0001 for period 1, 2 and 3, respectively). The median OS from T0 in the overall series was 7 months and there was no difference

among the three periods of time (7 vs 9 vs 7 months, p=0.722). Patients who received ≤3 prior lines of therapy had a significantly longer OS from T0 than patients who had received more than 3 lines (median 9 vs. 5 months, p=0.005). On the contrary, there was no difference in OS between patients treated only with conventional chemotherapy or those exposed to novel drugs (median 7 vs 7 months, p=NS). **Conclusions:** The median OS of patients who start palliative treatment with CP is 7 months. This survival has remained similar over the last 50 years and is not influenced by the period of time or previous exposure to novel drugs. However, the number of prior lines of therapy has a significant impact on OS, being shorter for those patients who start palliative treatment after more than 3 prior lines.

Introduction: Isatuximab is an anti-CD38 monoclonal antibody (mAb) that improves outcomes and depth of response in patients with relapsed or refractory multiple myeloma (MM). Serum Immunofixation (IF) is referenced in the IMWG guidelines for assessing complete response (CR) in MM. Isatuximab is an IgG-κ mAb detected by IF, which interferes with interpretation of CR. To avoid this interference and assist in accurate clinical assessment and therapeutic monitoring of MM patients, the HYDRASHIFT 2/4 Isatuximab (HYDRASHIFT Isa IF assay) was developed by Sebia with Sanofi. It has been utilized in determining final CR in the IKEMA study (Lancet 2021, Blood Cancer J 2023). The HYDRASHIFT Isa IF assay, intended for use on the HYDRASYS system, was evaluated for providing accurate M-protein detection and CR assessment in MM. We used different IF systems in analyzing the sera of MM patients who are being given treatments containing Isatuximab in order to examine differences in M-protein detection ability and CR assessment. **Methods:** Samples from 5 patients whose treatments included isatuximab were tested and monitored with IF on the HYDRASYS system (Sebia) using HYDRASHIFT 2/4 Isatuximab kit (Sebia) and with IF on the Epalyzer2 system (Helena). Serum FLCs and immunoglobulins (IGs) concentration were also measured. **Results:** The median age of 5 patients (3 males and 2 females) was 73 years (range; 49-79). The HYDRASHIFT Isa IF assay completely removed the Isatuximab-based IgG-κ band from the gamma region and changed 2 of 5 patients on the response evaluations to CR. Three patients showed M-proteins, IgG-κ, IgG-λ, IgA-κ, and free kappa (BJP-κ) that originated from MM. One patient with serious renal impairment having high serum FLC (κ: 1585 mg/L and λ: 6.9 mg/L), was found to have an IgA-κ and two BJP-κ monoclonal bands by HYDRASHIFT Isa IF assay. In this patient, the Epalyzer2 detected only the IgG-κ from Isatuximab, an IgA band with no associated light chain, and one weak BJP-κ. During monitoring by the HYDRASHIFT Isa IF assay, one of the two CR patients had a weak IgA-κ detected, indicating disease progression. However, the Epalyzer2 couldn't detect this IgA-κ and only detected IgG-κ originating from Isatuximab. **Conclusions:** The HYDRASYS system and HYDRASHIFT Isa IF assay was shown to have high sensitivity and specificity, providing accurate CR assessment, and also correctly identified serum BJP and a small M-protein. These results suggest that the response and CR assessments of patients can differ depending on the IF system used. In the clinical practice of MM in patients being treated with isatuximab, the use of the HYDRASHIFT Isa IF assay showed good performance regarding the proper CR and M-protein interpretation. These studies suggest that a "proper" CR assessment of isatuximab-treated patients would be increased by use of HYDRASHIFT Isa IF assay.

ALLG MM25 (VIBER-M): a phase Ib/II study of venetoclax, iberdomide and dexamethasone for patients in first or second relapse of multiple myeloma with t(11;14)

Shirlene Sim[1], Ann Solterbeck[2], Cecily Forsyth[3], Jay Hocking[4], Ian Kerridge[5], Hock-Choong Lai[6], Olga Motorna[7], Hang Quach[1]

[1]St Vincent's Hospital Melbourne, VIC, Australia; [2]Statistical Revelations; [3]Gosford Hospital, NSW, Australia; [4]Austin Health, VIC, Australia; [5]Royal North Shore Hospital, NSW, Australia; [6]Townsville University Hospital, QLD, Australia; [7]Eastern Health, VIC, Australia

Introduction: Translocation t(11;14) is an initiating lesion that is seen in approximately 20% of patients with multiple myeloma (MM). It is considered an intermediate-risk lesion and is associated with inferior outcomes amongst the intermediate risk-group. This is the only cytogenetic lesion in MM that is amenable to targeted treatment with Bcl2-inhibition. Venetoclax (Ven) is a Bcl2-inhibitor that induces cell death, and has been shown to be highly efficacious in patients with relapsed/refractory myeloma (RRMM) who harbour t(11;14) and high Bcl2 levels. Given that there is a significant attrition rate in patient numbers with each subsequent line of therapy, there is a need to move Bcl2-inhibitors to earlier lines of treatment to optimise clinical outcomes. In the current era where lenalidomide (len) maintenance is used in first line, there is a need for a len-free regimen at relapse. Iberdomide is a potent cereblon E3 ligase modulator (CELMod) that has been shown in pre-clinical studies to have direct anti-myeloma and immunostimulatory activity, including in len- and pomalidomide-resistant cell lines. Early studies in heavily pre-treated RRMM have demonstrated good response rates when iberdomide is combined with standard-of-care therapy. We hypothesize that the combination of Ven, iberdomide (Iber) and dexamethasone (Dex) will be highly synergistic and have better utility in rescuing MM patients with t(11;14) at first or second relapse. **Methods:** Treatment will be administered as an all oral regimen in a 28-day cycle: Ven on Days 1-28; Iber on Days 1-21; and weekly Dex. An adverse-event adapted trial design is used in anticipation of overlapping haematological toxicities between Ven and Iber, mainly

among the three periods of time (7 vs 9 vs 7 months, p=0.722). Patients who received ≤3 prior lines of therapy had a significantly longer OS from T0 than patients who had received more than 3 lines (median 9 vs. 5 months, p=0.005). On the contrary, there was no difference in OS between patients treated only with conventional chemotherapy or those exposed to novel drugs (median 7 vs 7 months, p=NS). **Conclusions:** The median OS of patients who start palliative treatment with CP is 7 months. This survival has remained similar over the last 50 years and is not influenced by the period of time or previous exposure to novel drugs. However, the number of prior lines of therapy has a significant impact on OS, being shorter for those patients who start palliative treatment after more than 3 prior lines.

Introduction: Translocation t(11;14) is an initiating lesion that is seen in approximately 20% of patients with multiple myeloma (MM). It is considered an intermediate-risk lesion and is associated with inferior outcomes amongst the intermediate risk-group. This is the only cytogenetic lesion in MM that is amenable to targeted treatment with Bcl2-inhibition. Venetoclax (Ven) is a Bcl2-inhibitor that induces cell death, and has been shown to be highly efficacious in patients with relapsed/refractory myeloma (RRMM) who harbour t(11;14) and high Bcl2 levels. Given that there is a significant attrition rate in patient numbers with each subsequent line of therapy, there is a need to move Bcl2-inhibitors to earlier lines of treatment to optimise clinical outcomes. In the current era where lenalidomide (len) maintenance is used in first line, there is a need for a len-free regimen at relapse. Iberdomide is a potent cereblon E3 ligase modulator (CELMod) that has been shown in pre-clinical studies to have direct anti-myeloma and immunostimulatory activity, including in len- and pomalidomide-resistant cell lines. Early studies in heavily pre-treated RRMM have demonstrated good response rates when iberdomide is combined with standard-of-care therapy. We hypothesize that the combination of Ven, iberdomide (Iber) and dexamethasone (Dex) will be highly synergistic and have better utility in rescuing MM patients with t(11;14) at first or second relapse. **Methods:** Treatment will be administered as an all oral regimen in a 28-day cycle: Ven on Days 1-28; Iber on Days 1-21; and weekly Dex. An adverse-event adapted trial design is used in anticipation of overlapping haematological toxicities between Ven and Iber, mainly

neutropenia. There will be intra-patient dose escalation over the first three cycles; if there is no Grade 3 neutropenia with fever or Grade 4 neutropenia lasting more than 5 days, Grade 4 thrombocytopenia or ≥Grade 3 treatment-related non-haematological toxicities, doses will be escalated (Cycle 1: Iber 1.3mg/Ven 200mg; Cycle 2: Iber 1.3mg/Ven 400mg; Cycle 3 onwards: Iber 1.6mg/Ven 400mg). Three safety assessments will be carried out after five patients have completed cycle 1, 2 and 3 respectively. Treatment will be until disease progression. Primary endpoint is achievement of very good partial response or better. Total study duration will be 4.5 years, with recruitment over 24 months, median expected time on treatment of 24 months, and follow up until 6 months after the last patient has had their last dose of treatment. This research is a cooperative trial group study lead by the Australasian Leukaemia and Lymphoma Group (ALLG), as ALLG MM25. This study is supported by AbbVie Inc. and Bristol-Myers Squibb Company. **Conclusions:** We anticipate that combination Ven-Iber-Dex will be well tolerated and result in deep and durable remission in MM patients with t(11;14) in first or second relapse.

Bendamustine salvage for relapsed – refractory multiple myeloma: a retrospective analysis of outcomes in heavily pretreated patients

Aakanksha Singh[1], Narendra Agrawal[1], Rohan Haldar[1], Dinesh Bhurani[1], Jyoti Shankar Raychoudhari[1]

[1]Rajiv Gandhi Cancer institute and Research Center

Introduction: Multiple myeloma in first-line or second-line setting are exposed and hence become refractory to IMIDs, PIs and monoclonal antibodies. The response rates of bendamustine in relapsed/ refractory multiple myeloma ranged from 20 to 30% for monotherapy to >80% for triple-drug combinations. **Methods:** From Jan 2016 to July 2022, 50 patients of RRMM after two or more lines of therapy were included. ORR (overall response rate) defined as a partial response or more after two cycles to a maximum of 6 cycles. Bendamustine in combination with Pomalidomide/ Carfilzomib/Bortezomib/Daratumumab/PAD chemotherapy and dexamethasone was given. **Results:** All patients had prior PI (including Carfilzomib) and IMid (including Pomalidomide) exposure. 28.0% patients had prior Daratumumab exposure. 48.0% patients had prior ASCT, 26.0% patients were Triple Refractory and 20.0% were Penta-Refractory. 46.0% patients had Plasmacytoma (Paraskeletal- 13, Extramedullary-10), 14% Circulating plasma cells, 16% Secondary amyloidosis and 22% High Risk cytogenetics. In total, 25 (50%) patients responded and included: CR-8.0%, VGPR-12.0% and PR-30.0%. No difference in ORR observed for presence or absence of Extra Medullary Disease (40% vs 46%), circulating plasma cells (57 % vs 48%), high risk cytogenetics (50% vs 52%) and RISS Stage III vs RISS Stage I/II (47.6% vs 52.4%) respectively. The response rates were similar in patients who relapsed after ASCT versus not (48% vs 52%), triple refractory (44% vs 56%) and penta refractory (42% vs 55%), respectively with p value>0.05. While Bendamustine/ Daratumumab and Bendamustine/ PAD showed impressive ORR of 87.5% and 75.0% respectively, the Bendamustine/ Pomalidomide, Bendamustine/ Carfilzomib and Bendamustine/ Bortezomib also showed an ORR of 42.9%, 37.5% and 47.1% respectively. Bendamustine/ Dexamethasone had a dismal ORR-16.7%. Patients /=3 cycles of chemotherapy (HR 1.29, 95% CI 1.01 – 1.80, p- 0.046). At a median follow-up of 11.5 months, median PFS and OS were 4 (95% CI: 2.25-5.00) months and 9.00 (95% CI: 5.25- not reached) months respectively. 32 (64%) of patients died on follow up. Patients with < CR in all prior lines of therapy had inferior OS, HR 1.39 (95% CI: 1.15-2.00, p=0.050) and PFS (HR 1.39, 95% CI: 1.15-1.99, p-0.050). Triple refractory myeloma (HR 1.32, 95% CI: 1.17-1.62, p-0.001) and Penta refractory (HR 1.21, 95% CI: 1.10-1.46, p< 0.001) had an inferior PFS. 8% patients had Grade 3/4 hematological toxicity requiring dose reduction. **Conclusions:** Bendamustine showed encouraging responses across all risk groups, high burden disease and heavily pretreated patients post exposure to novel agents, making an excellent bridging therapy to bispecifics, off the shelf allogenic CARs and NK- CARs.

Elranatamab exposure-safety analysis in patients with relapsed/refractory multiple myeloma: analysis from MagnetisMM studies

Pooneh Soltantabar[1], Donald Irby[1], Jennifer Hibma[1], Diane Wang[1], Jason Williams[1], Akos Czibere[1], Andrea Viqueira[2], Anne Hickman[1], Mohamed Elmeliegy[1]

[1]Pfizer Inc.; [2]Pfizer SLU, Madrid, Spain

Introduction: Elranatamab was demonstrated to be an effective treatment for patients (pts) with RRMM with a manageable safety profile based on the results from the Phase 2 (Ph2) MagnetisMM-3 trial (NCT04649359). This analysis explored the exposure-response (ER) for infections, neutropenia and peripheral neuropathy. **Methods:** The ER-safety analysis of elranatamab was performed using pooled data from 4 studies: MagnetisMM-1 (first-in-human Ph1, NCT03269136), MagnetisMM-2 (Japan Ph1, NCT04798586), MagnetisMM-3 (Ph2), and MagnetisMM-9 (Ph1/2, NCT05014412). These studies included a dose range of 0.1 to 50 µg/kg IV and 80 to 1000 µg/kg (6 to 76 mg) QW SC. Binomial logistic regression was used. The safety endpoints were Grade ≥ 3 (G3+) neutropenia, G3+ infections and Grade ≥ 2 (G2+) peripheral neuropathy. Base models explored free (ie, unbound) and total (ie, free and sBCMA-bound) elranatamab PK on the probability of developing each of the selected safety endpoints. Average exposure up to the event (Cave,event) was used as the PK metric in this analysis. A Full model was developed for each safety endpoint to explore the influence of clinical and laboratory covariates and PK. Stepwise backward elimination (α =0.01) was used for covariate selection and final model development. **Results:** Out of 324 participants treated with elranatamab monotherapy, 47%, 35% and 9% experienced G3+ neutropenia, G3+ infection and G2+ peripheral neuropathy. The median (range) time to first event of G3+ neutropenia and G3+ infection was 43.00 (4 - 312) and 79.5 (4 - 428) days, respectively. Given the distribution of the time to first instance of these events, C_ave,event was used as the exposure metric. For neutropenia, base

neutropenia. There will be intra-patient dose escalation over the first three cycles; if there is no Grade 3 neutropenia with fever or Grade 4 neutropenia lasting more than 5 days, Grade 4 thrombocytopenia or ≥Grade 3 treatment-related non-haematological toxicities, doses will be escalated (Cycle 1: Iber 1.3mg/Ven 200mg; Cycle 2: Iber 1.3mg/Ven 400mg; Cycle 3 onwards: Iber 1.6mg/Ven 400mg). Three safety assessments will be carried out after five patients have completed cycle 1, 2 and 3 respectively. Treatment will be until disease progression. Primary endpoint is achievement of very good partial response or better. Total study duration will be 4.5 years, with recruitment over 24 months, median expected time on treatment of 24 months, and follow up until 6 months after the last patient has had their last dose of treatment. This research is a cooperative trial group study lead by the Australasian Leukaemia and Lymphoma Group (ALLG), as ALLG MM25. This study is supported by AbbVie Inc. and Bristol-Myers Squibb Company. **Conclusions:** We anticipate that combination Ven-Iber-Dex will be well tolerated and result in deep and durable remission in MM patients with t(11;14) in first or second relapse.

The response rates of bendamustine in relapsed/ refractory multiple myeloma ranged from 20 to 30% for monotherapy to >80% for triple-drug combinations. **Methods:** From Jan 2016 to July 2022, 50 patients of RRMM after two or more lines of therapy were included. ORR (overall response rate) defined as a partial response or more after two cycles to a maximum of 6 cycles. Bendamustine in combination with Pomalidomide/ Carfilzomib/Bortezomib/Daratumumab/PAD chemotherapy and dexamethasone was given. **Results:** All patients had prior PI (including Carfilzomib) and IMid (including Pomalidomide) exposure. 28.0% patients had prior Daratumumab exposure. 48.0% patients had prior ASCT, 26.0% patients were Triple Refractory and 20.0% were Penta-Refractory. 46.0% patients had Plasmacytoma (Paraskeletal- 13, Extramedullary-10), 14% Circulating plasma cells, 16% Secondary amyloidosis and 22% High Risk cytogenetics. In total, 25 (50%) patients responded and included: CR-8.0%, VGPR-12.0% and PR-30.0%. No difference in ORR observed for presence or absence of Extra Medullary Disease (40% vs 46%), circulating plasma cells (57 % vs 48%), high risk cytogenetics (50% vs 52%) and RISS Stage III vs RISS Stage I/II (47.6% vs 52.4%) respectively. The response rates were similar in patients who relapsed after ASCT versus not (48% vs 52%), triple refractory (44% vs 56%) and penta refractory (42% vs 55%), respectively with p value>0.05. While Bendamustine/ Daratumumab and Bendamustine/ PAD showed impressive ORR of 87.5% and 75.0% respectively, the Bendamustine/ Pomalidomide, Bendamustine/ Carfilzomib and Bendamustine/ Bortezomib also showed an ORR of 42.9%, 37.5% and 47.1% respectively. Bendamustine/ Dexamethasone had a dismal ORR-16.7%. Patients /=3 cycles of chemotherapy (HR 1.29, 95% CI 1.01 – 1.80, p- 0.046). At a median follow-up of 11.5 months, median PFS and OS were 4 (95% CI: 2.25-5.00) months and 9.00 (95% CI: 5.25- not reached) months respectively. 32 (64%) of patients died on follow up. Patients with < CR in all prior lines of therapy had inferior OS, HR 1.39 (95% CI: 1.15-2.00, p=0.050) and PFS (HR 1.39, 95% CI: 1.15-1.99, p-0.050). Triple refractory myeloma (HR 1.32, 95% CI: 1.17-1.62, p-0.001) and Penta refractory (HR 1.21, 95% CI: 1.10-1.46, p< 0.001) had an inferior PFS. 8% patients had Grade 3/4 hematological toxicity requiring dose reduction. **Conclusions:** Bendamustine showed encouraging responses across all risk groups, high burden disease and heavily pretreated patients post exposure to novel agents, making an excellent bridging therapy to bispecifics, off the shelf allogenic CARs and NK- CARs.

Elranatamab exposure-safety analysis in patients with relapsed/refractory multiple myeloma: analysis from MagnetisMM studies

Pooneh Soltantabar[1], Donald Irby[1], Jennifer Hibma[1], Diane Wang[1], Jason Williams[1], Akos Czibere[1], Andrea Viqueira[2], Anne Hickman[1], Mohamed Elmeliegy[1]

[1]Pfizer Inc.; [2]Pfizer SLU, Madrid, Spain

Introduction: Elranatamab was demonstrated to be an effective treatment for patients (pts) with RRMM with a manageable safety profile based on the results from the Phase 2 (Ph2) MagnetisMM-3 trial (NCT04649359). This analysis explored the exposure-response (ER) for infections, neutropenia and peripheral neuropathy. **Methods:** The ER-safety analysis of elranatamab was performed using pooled data from 4 studies: MagnetisMM-1 (first-in-human Ph1, NCT03269136), MagnetisMM-2 (Japan Ph1, NCT04798586), MagnetisMM-3 (Ph2), and MagnetisMM-9 (Ph1/2, NCT05014412). These studies included a dose range of 0.1 to 50 µg/kg IV and 80 to 1000 µg/kg (6 to 76 mg) QW SC. Binomial logistic regression was used. The safety endpoints were Grade ≥ 3 (G3+) neutropenia, G3+ infections and Grade ≥ 2 (G2+) peripheral neuropathy. Base models explored free (ie, unbound) and total (ie, free and sBCMA-bound) elranatamab PK on the probability of developing each of the selected safety endpoints. Average exposure up to the event (Cave,event) was used as the PK metric in this analysis. A Full model was developed for each safety endpoint to explore the influence of clinical and laboratory covariates and PK. Stepwise backward elimination (α =0.01) was used for covariate selection and final model development. **Results:** Out of 324 participants treated with elranatamab monotherapy, 47%, 35% and 9% experienced G3+ neutropenia, G3+ infection and G2+ peripheral neuropathy. The median (range) time to first event of G3+ neutropenia and G3+ infection was 43.00 (4 - 312) and 79.5 (4 - 428) days, respectively. Given the distribution of the time to first instance of these events, C_ave,event was used as the exposure metric. For neutropenia, base

neutropenia. There will be intra-patient dose escalation over the first three cycles; if there is no Grade 3 neutropenia with fever or Grade 4 neutropenia lasting more than 5 days, Grade 4 thrombocytopenia or ≥Grade 3 treatment-related non-haematological toxicities, doses will be escalated (Cycle 1: Iber 1.3mg/Ven 200mg; Cycle 2: Iber 1.3mg/Ven 400mg; Cycle 3 onwards: Iber 1.6mg/Ven 400mg). Three safety assessments will be carried out after five patients have completed cycle 1, 2 and 3 respectively. Treatment will be until disease progression. Primary endpoint is achievement of very good partial response or better. Total study duration will be 4.5 years, with recruitment over 24 months, median expected time on treatment of 24 months, and follow up until 6 months after the last patient has had their last dose of treatment. This research is a cooperative trial group study lead by the Australasian Leukaemia and Lymphoma Group (ALLG), as ALLG MM25. This study is supported by AbbVie Inc. and Bristol-Myers Squibb Company. **Conclusions:** We anticipate that combination Ven-Iber-Dex will be well tolerated and result in deep and durable remission in MM patients with t(11;14) in first or second relapse.

Bendamustine salvage for relapsed – refractory multiple myeloma: a retrospective analysis of outcomes in heavily pretreated patients

Aakanksha Singh[1], Narendra Agrawal[1], Rohan Haldar[1], Dinesh Bhurani[1], Jyoti Shankar Raychoudhari[1]

[1]Rajiv Gandhi Cancer institute and Research Center

Introduction: Multiple myeloma in first-line or second-line setting are exposed and hence become refractory to IMIDs, PIs and monoclonal antibodies. The response rates of bendamustine in relapsed/ refractory multiple myeloma ranged from 20 to 30% for monotherapy to >80% for triple-drug combinations. **Methods:** From Jan 2016 to July 2022, 50 patients of RRMM after two or more lines of therapy were included. ORR (overall response rate) defined as a partial response or more after two cycles to a maximum of 6 cycles. Bendamustine in combination with Pomalidomide/ Carfilzomib/Bortezomib/Daratumumab/PAD chemotherapy and dexamethasone was given. **Results:** All patients had prior PI (including Carfilzomib) and IMid (including Pomalidomide) exposure. 28.0% patients had prior Daratumumab exposure. 48.0% patients had prior ASCT, 26.0% patients were Triple Refractory and 20.0% were Penta-Refractory. 46.0% patients had Plasmacytoma (Paraskeletal- 13, Extramedullary-10), 14% Circulating plasma cells, 16% Secondary amyloidosis and 22% High Risk cytogenetics. In total, 25 (50%) patients responded and included: CR-8.0%, VGPR-12.0% and PR-30.0%. No difference in ORR observed for presence or absence of Extra Medullary Disease (40% vs 46%), circulating plasma cells (57 % vs 48%), high risk cytogenetics (50% vs 52%) and RISS Stage III vs RISS Stage I/II (47.6% vs 52.4%) respectively. The response rates were similar in patients who relapsed after ASCT versus not (48% vs 52%), triple refractory (44% vs 56%) and penta refractory (42% vs 55%), respectively with p value>0.05. While Bendamustine/ Daratumumab and Bendamustine/ PAD showed impressive ORR of 87.5% and 75.0% respectively, the Bendamustine/ Pomalidomide, Bendamustine/ Carfilzomib and Bendamustine/ Bortezomib also showed an ORR of 42.9%, 37.5% and 47.1% respectively. Bendamustine/ Dexamethasone had a dismal ORR-16.7%. Patients /=3 cycles of chemotherapy (HR 1.29, 95% CI 1.01 – 1.80, p- 0.046). At a median follow-up of 11.5 months, median PFS and OS were 4 (95% CI: 2.25-5.00) months and 9.00 (95% CI: 5.25- not reached) months respectively. 32 (64%) of patients died on follow up. Patients with < CR in all prior lines of therapy had inferior OS, HR 1.39 (95% CI: 1.15-2.00, p=0.050) and PFS (HR 1.39, 95% CI: 1.15-1.99, p-0.050). Triple refractory myeloma (HR 1.32, 95% CI: 1.17-1.62, p-0.001) and Penta refractory (HR 1.21, 95% CI: 1.10-1.46, p< 0.001) had an inferior PFS. 8% patients had Grade 3/4 hematological toxicity requiring dose reduction. **Conclusions:** Bendamustine showed encouraging responses across all risk groups, high burden disease and heavily pretreated patients post exposure to novel agents, making an excellent bridging therapy to bispecifics, off the shelf allogenic CARs and NK- CARs.

Introduction: Elranatamab was demonstrated to be an effective treatment for patients (pts) with RRMM with a manageable safety profile based on the results from the Phase 2 (Ph2) MagnetisMM-3 trial (NCT04649359). This analysis explored the exposure-response (ER) for infections, neutropenia and peripheral neuropathy. **Methods:** The ER-safety analysis of elranatamab was performed using pooled data from 4 studies: MagnetisMM-1 (first-in-human Ph1, NCT03269136), MagnetisMM-2 (Japan Ph1, NCT04798586), MagnetisMM-3 (Ph2), and MagnetisMM-9 (Ph1/2, NCT05014412). These studies included a dose range of 0.1 to 50 µg/kg IV and 80 to 1000 µg/kg (6 to 76 mg) QW SC. Binomial logistic regression was used. The safety endpoints were Grade ≥ 3 (G3+) neutropenia, G3+ infections and Grade ≥ 2 (G2+) peripheral neuropathy. Base models explored free (ie, unbound) and total (ie, free and sBCMA-bound) elranatamab PK on the probability of developing each of the selected safety endpoints. Average exposure up to the event (Cave,event) was used as the PK metric in this analysis. A Full model was developed for each safety endpoint to explore the influence of clinical and laboratory covariates and PK. Stepwise backward elimination (α =0.01) was used for covariate selection and final model development. **Results:** Out of 324 participants treated with elranatamab monotherapy, 47%, 35% and 9% experienced G3+ neutropenia, G3+ infection and G2+ peripheral neuropathy. The median (range) time to first event of G3+ neutropenia and G3+ infection was 43.00 (4 - 312) and 79.5 (4 - 428) days, respectively. Given the distribution of the time to first instance of these events, C_ave,event was used as the exposure metric. For neutropenia, base

model results indicated that total C_ave,event was not significantly associated (P-value=0.4307) with G3+ neutropenia, however, free C_ave,event was significant (P-value=0.0272). For infections, total C_ave,event was not significantly associated with G3+ infections (P-value=0.1918), however, free C_ave,event was significant (P-value=0.0362). Neither the exposure metrics nor the clinical or laboratory covariates were retained in the final models after backward elimination. For peripheral neuropathy, the analysis dataset included a total of 29 events of G2+ peripheral neuropathy which did not allow for a statistical analysis. However, there was no apparent ER relationship by visual inspection of diagnostic plots and exposure in participants with G2+ peripheral neuropathy was within the range of those without events. **Conclusions:** No statistically significant relationship was observed between elranatamab exposure (free or total Cave,event) and the incidence of G3+ AEs of neutropenia/infection and G2+ peripheral neuropathy. Elranatamab demonstrated a relatively flat exposure-safety profile. This finding together with the meaningful clinical benefit observed in the MagnetisMM-3 study indicates a favorable benefit-risk for elranatamab at the 76 mg QW/Q2W regimen.

NK cell kinetics predict outcome in the multiple treated with elotuzumab, lenalidomide plus dexamethasone (ERd): a subanalysis in Japanese multicenter observation for once monthly ERd study

Kazuhito Suzuki[1], Morio Matsumoto[2], Naoki Takezako[3], Yasushi Hiramatsu[4], Yotaro Tamai[5], Shingo Yano[1], Kenshi Suzuki[6]

[1]The Jikei University School of Medicine; [2]Shibukawa Medical Center; [3]Nerima Hikarigaoka Hospital; [4]Japanese Red Cross Society Himeji Hospital; [5]Shonan Kamakura General Hospital; [6]Japanese Red Cross Medical Center, Tokyo, Japan

Introduction: Elotuzumab, lenalidomide plus dexamethasone (ERd) is a standard salvage chemotherapy for myeloma, and elotuzumab is commonly administered every 2 weeks after cycle 3 (conventional ERd). Alternatively, elotuzumab may often be used every four weeks (monthly ERd) in real-world practice. Additionally, the immune profile was not investigated in the patients who received long-term ERd. The purpose of this multicenter observational study was to investigate the efficacy of monthly ERd and kinetics of NK cell in the patients treated with ERd. **Methods:** We analyzed the efficacy between conventional and monthly ERd for the myeloma patients in six institutes retrospectively. Moreover, we investigated the kinetics of natural killer (NK) cell by 2color flow cytometry (FCM) using peripheral blood samples, which were collected on day1 of ERd every cycles. The percentage of NK cells was analyzed by CD2+CD16+ fraction. The activity of NK cells was evaluated by FCM using CD16 and CD57 antigens. CD16+CD57-, CD16+CD57+, CD16-CD57+ fractions show high, intermediate, and low NK activities, respectively. **Results:** Seventy-five patients were included in this study. The median age was 68 years. The median number of prior chemotherapies was two (1-5). The number of progressive disease (PD) and non-PD before ERd were 23 (30.7%) and 52 (69.3%), respectively. The frequency of PD before ERd was significantly lower in the monthly ERd group than in the conventional ERd group. In 26.9 months of median follow-up period, the 2-year progression-free survival (PFS) rate in the monthly ERd group was significantly longer than that in the conventional ERd group (95.0% and 62.0%, hazard ratio 0.082, P = 0.002). Concerning the kinetic of NK cells, we investigated the lymphocyte kinetics in twenty-one patients, including 12 of monthly ERd, 5 of PD before ERd, and 8 of PD after ERd groups. The median duration of ERd was 22.6 months, and the cutoff time for long ERd continuation was 2years. There was no significant difference of the NK cell percentage and activity between the monthly and conventional ERd groups. The NK cell percentage was significantly increasing overtime in the long ERd group compared to those in the short ERd group (P = 0.035). There was no significant difference of the NK cell activity between the long and short ERd groups. The low activity NK cell percentage was significantly increasing in the patients whose ERd outcome was PD even if ERd was effective, which was named PD after ERd group, compared to those in the non-PD after ERd group (P < 0.001). There was no significant difference of high and intermediate activity NK cell percentages between the PD and non-PD after ERd groups. **Conclusions:** The efficacy of monthly ERd might be similar to those of conventional ERd, and monthly ERd might be an option considering balance between cost and effectiveness. The monthly ERd did not affect the kinetic of NK cell. The low activated NK cell percentage was increasing in the PD after ERd group.

How do patients and providers value innovative multiple myeloma treatments? Evidence from a discrete choice experiment

Sakil Syeed[1], Chia Jie Tan[1], Amandeep Godara[2], Kyna Gooden[3], Derek Tang[3], Samantha Slaff[3], Surachat Ngorsuraches[4], Nathorn Chaiyakunapruk[1]

[1]University of Utah College of Pharmacy, Salt Lake City, UT; [2]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; [3]WW HEOR Markets, Bristol Myers Squibb, Princeton, NJ; [4]Auburn University Harrison College of Pharmacy Auburn, AL, USA

Introduction: Survival improvement for patients (pts) with multiple myeloma (MM) is attributed to innovative treatments (Tx). The impact of these innovative Tx is generally measured through disease improvement and pt survival; however, the value ascribed to innovation remains unclear. Understanding pt and healthcare provider (HCP) preferences for innovation can help support shared decision-making and improve pt outcomes. This study aimed to investigate pt and HCP preferences for innovative MM Tx. **Methods:** This mixed methods research study leveraged qualitative and quantitative approaches to understand perspectives among pts with MM and HCPs regarding the value of innovation in MM. A literature review, followed by interviews with pts and HCPs, were conducted to identify treatment attributes, and 5 attributes were selected. Tx alternatives were characterized by varying levels of (1) progression-free survival (PFS: 6, 12, 24, 48 months); (2) probability

model results indicated that total C_ave,event was not significantly associated (P-value=0.4307) with G3+ neutropenia, however, free C_ave,event was significant (P-value=0.0272). For infections, total C_ave,event was not significantly associated with G3+ infections (P-value=0.1918), however, free C_ave,event was significant (P-value=0.0362). Neither the exposure metrics nor the clinical or laboratory covariates were retained in the final models after backward elimination. For peripheral neuropathy, the analysis dataset included a total of 29 events of G2+ peripheral neuropathy which did not allow for a statistical analysis. However, there was no apparent ER relationship by visual inspection of diagnostic plots and exposure in participants with G2+ peripheral neuropathy was within the range of those without events. **Conclusions:** No statistically significant relationship was observed between elranatamab exposure (free or total Cave,event) and the incidence of G3+ AEs of neutropenia/infection and G2+ peripheral neuropathy. Elranatamab demonstrated a relatively flat exposure-safety profile. This finding together with the meaningful clinical benefit observed in the MagnetisMM-3 study indicates a favorable benefit-risk for elranatamab at the 76 mg QW/Q2W regimen.

Introduction: Survival improvement for patients (pts) with multiple myeloma (MM) is attributed to innovative treatments (Tx). The impact of these innovative Tx is generally measured through disease improvement and pt survival; however, the value ascribed to innovation remains unclear. Understanding pt and healthcare provider (HCP) preferences for innovation can help support shared decision-making and improve pt outcomes. This study aimed to investigate pt and HCP preferences for innovative MM Tx. **Methods:** This mixed methods research study leveraged qualitative and quantitative approaches to understand perspectives among pts with MM and HCPs regarding the value of innovation in MM. A literature review, followed by interviews with pts and HCPs, were conducted to identify treatment attributes, and 5 attributes were selected. Tx alternatives were characterized by varying levels of (1) progression-free survival (PFS: 6, 12, 24, 48 months); (2) probability

of severe side effects (5%, 10%, 20%); (3) how pts live with MM Tx (living without Tx, living with Tx at home, living with Tx at a hospital); (4) scientific innovation, defined as a Tx that is either first-in-class or leads to future development of better MM Tx (yes, no); and (5) monthly OOP cost ($100, $500, $1000, $1500). A Tx that provides the opportunity to live without Tx and/or offers scientific innovation was deemed innovative. Subsequently, discrete choice experiment surveys were conducted. Choice data were analyzed using mixed logit (ML) models. **Results:** Forty-seven pts participated in this interim analysis. The average age was 62.4 years; most were female (n=29, 62%) and had experienced relapse (n=30, 64%). The ML model revealed that pts preferred increased PFS, less severe side effects, a Tx that offered life without Tx, scientific innovation, and lower OOP cost. PFS had the highest conditional relative importance (37%) from the pts' perspective, followed by the OOP cost (27%) and how they live with MM Tx (17%). Of the 30 HCPs, 50% were physicians (n=15), 30% were nurses (n=9), and 20% were pharmacists (n=6). The findings of the ML model were consistent with the pt survey. PFS had the highest conditional relative importance from the HCPs' perspective (31%), followed by how pts live with MM Tx (22%) and scientific innovation (19%). **Conclusions:** Our findings show that pts and HCPs positively valued innovative MM Tx that provided the opportunity to live without Tx and/or offered scientific innovation. Not accounting for the value of innovation would result in underestimation of its value and potentially lead to less access to innovation and less R&D investment for future innovation.

Introduction: Pomalidomide-dexamethasone (Pd) has been a standard of care treatment for myeloma since 2013. Due to the current treatment algorithms, pomalidomide is mostly used in patients already exposed to a CD38 antibody. However, the clinical performance of pomalidomide in the era of CD38 antibodies is largely unknown. **Methods:** Here we describe the real-world use and efficacy of pomalidomide in a complete Danish, nationwide cohort of daratumumab-exposed patients. We conducted a nationwide retrospective review of the clinical course of all patients treated with a daratumumab-containing regimen prior to 1.1.2019. Treatment data were updated until 1.1.2021. **Results:** We identified 328 patients that were treated with pomalidomide. Of these, 137 received Pd, 65 daratumumab-pomalidomide-dexamethasone (DPD), 43 pomalidomide-cyclophosphamide-dexamethasone (PCD), 19 carfilzomib-pomalidomide-dexamethasone (KPD), 11 pomalidomide-bortezomib-dexamethasone (PVD) and 52 pomalidomide in other combinations. Patients treated with Pd had a partial response or better rate (>=PR) of 35.8% and median time to next treatment (mTNT) of 4.9 months, almost identical to previous prospective clinical trials. Although treatment with the various pomalidomide-containing triplet regimens resulted in higher >=PR rates (PCD: 46.5%, PVD: 63.6%, DPD: 55.4%, KPD: 63.2%), the achieved mTNT was not significantly better than what was achieved with Pd (PCD: 5.4, PVD: 5.3, DPD: 4.7 months). The exemption to this was KPD (mTNT 7.4 months), but this regimen was used earlier in the course of the disease. The most important predictor of outcomes, rather than the choice of index regimen (p=0.72), was prior exposure (p=0.0116). Compared to CD38 antibody-naïve patients, patients previously treated with a CD38 antibody had reduced partial response or better rate (38.0% vs 47.3%), shorter median TNT (4.0 vs 5.9 months), and shorter median OS (12.4 vs 24.2 months) on pomalidomide treatment. **Conclusions:** In this large real-world cohort, the clinical performance of Pd was almost identical to the results of prospective clinical trials. Although treatment with the various pomalidomide-containing triplet regimens resulted in higher response rates, the achieved TNT was not better than what was achieved with Pd. Compared to CD38 antibody-naïve patients, patients previously treated with a CD38 antibody achieved worse outcomes with pomalidomide.

Introduction: The use of lenalidomide in frontline therapy for patients with newly diagnosed multiple myeloma (MM) has increased the number of those who become refractory to lenalidomide at second line. In this context, we assessed the efficacy of daratumumab in combination with ixazomib and dexamethasone (Dara-Ixa-dex). **Methods:** DARIA was a prospective, open-label, multicenter, phase 2 study. Eligible adult patients had relapsed/refractory MM (RRMM) after one prior line with a lenalidomide-based regimen and a Karnofsky Performance Status (KPS) score of ≥70. Treatment with Dara-Ixa-dex comprised an induction phase of nine 28-days cycles and a maintenance phase. During induction, patients received Dara at the approved schedule, 4mg oral ixazomib (days 1, 8, and 15 of each cycle) and 40mg oral dexamethasone weekly. In maintenance, Dara-Ixa were administered every 4 weeks until disease progression or unacceptable toxicity, with dexamethasone being discontinued. The primary endpoint was overall response rate (ORR). Secondary endpoints included progression-free survival (PFS), the toxicity profile of Dara-Ixa-dex, and the effects of the combination on serum bone metabolism markers (C-terminal telopeptide of type 1 collagen [CTX], tartrate-resistant acid phosphatase isoform 5b [TRACP-5b], bone-specific alkaline phosphatase [bALP], and osteocalcin [OC]) from baseline until disease progression. **Results:** Overall, 50 patients were enrolled (median age: 69 (range 50-89) years; males: 28 [56%]). At screening, 38 (76%) patients had a KPS score ≥90, and most were at revised ISS stage I and II (n=47, 94%). 32 (64%) patients were refractory to lenalidomide, and 17 (34%) had prior ASCT. ORR was 64% (n=32); 1 (2%) patient had a complete response, 16 (32%) a very good partial response (VGPR), and 15 (30%) patients had a PR. The median (range) time from first treatment dose until first response (≥PR) was 1.0 (0.9-17.6) month. After a median (range) follow-up of 23.4 (1.1-47.6) months, the median PFS was 8.1 months (95%CI: 5.2-15.8) and the median OS was 39.2 months (95%CI: 17.4-39.3). Regarding bone metabolism indices, the median changes from baseline for CTX, TRACP-5b, bALP and OC were significant ($p< 0.05$) and became evident as early as at 6 months. At the end of the study, 13 (26%) patients were still on treatment; reasons for treatment discontinuation were progressive disease (n=29, 58%), physician's decision and fatal serious adverse event [SAE] (n=3, 6% each), and adverse event [AE] (n=2, 4%). Overall, 20 (40%) patients had ≥1 grade 3/4 AE, the most common being thrombocytopenia (n=10, 20%). 14 (28%) patients had ≥1 SAE, the most common being acute kidney injury and pneumonia (n=2, 4% each). Four fatal SAEs due to infections were reported. **Conclusions:** In conclusion, second-line treatment with Dara-Ixa-dex in patients with RRMM pre-treated with a lenalidomide-based regimen resulted in rapid (< 2 months) and satisfactory responses along with a favorable effect on bone metabolism.

Lurie Cancer Center, Northwestern Medicine, Chicago, IL, USA; [12]Bristol Myers Squibb, Princeton, NJ, USA; [13]Winship Cancer Institute, Emory University, Atlanta, GA, USA

Introduction: IBER is a novel, oral cereblon (CRBN) E3 ligase modulator (CELMoD™) with enhanced antimyeloma effects compared with immunomodulatory drugs (IMiDs®). In the phase 1/2 CC-220-MM-001 trial (NCT02773030), IBER+DEX showed meaningful clinical activity (overall response rate 32.2% in Cohort B [dose escalation], 26.2% in Cohort D [dose expansion]) in heavily pretreated RRMM; treatment-emergent adverse events (TEAEs) were mostly hematologic, consistent with the profile of a CRBN-modulating drug. Here we report the safety profile of IBER+DEX in Cohorts B and D. **Methods:** Patients (pts) received IBER on days (D) 1–21 at a dose range of 0.3–1.6mg (Cohort B) or at 1.6mg (Cohort D) with weekly DEX (40mg; 20mg if >75 years of age) of each 28-day cycle. Following a dose interruption, the IBER dose may be maintained if neutropenia was the only IBER-related toxicity and granulocyte-colony stimulating factor (G-CSF) was used. Primary endpoints were to determine recommended phase 2 dose (Cohort B) and efficacy (Cohort D); safety was a secondary endpoint. Pharmacokinetics (PK) samples were collected on D8, 15, and 22 in cycles 1–4 and a population PK model was developed to estimate IBER PK exposure, which was correlated with efficacy and safety endpoints to assess exposure–response (ER) relationships. **Results:** As of June 2, 2021, 197 pts had received IBER+DEX (90 in Cohort B, 107 in Cohort D). The most frequent grade (Gr) 3/4 TEAEs were neutropenia (38 [42.2%] pts), anemia (24 [26.7%] pts), and infections (23 [25.6%] pts) in Cohort B, and neutropenia (48 [44.9%] pts), anemia (30 [28.0%] pts), and infections (29 [27.1%] pts) in Cohort D. Excluding infections, Gr 3/4 non-hematologic TEAEs were low. Venous thromboembolism occurred in 4 (4.4%) pts in Cohort B and 5 (4.7%) pts in Cohort D. Seventy-four (82.2%) pts in Cohort B and 95 (88.8%) pts in Cohort D experienced at least 1 TEAE related to IBER. Median

Introduction: The use of lenalidomide in frontline therapy for patients with newly diagnosed multiple myeloma (MM) has increased the number of those who become refractory to lenalidomide at second line. Introduction: IBER is a novel, oral cereblon (CRBN) E3 ligase modulator (CELMoD™) with enhanced antimyeloma effects compared with immunomodulatory drugs (IMiDs®). In the phase 1/2 CC-220-MM-001 trial (NCT02773030), IBER+DEX showed meaningful clinical activity (overall response rate 32.2% in Cohort B [dose escalation], 26.2% in Cohort D [dose expansion]) in heavily pretreated RRMM; treatment-emergent adverse events (TEAEs) were mostly hematologic, consistent with the profile of a CRBN-modulating drug. Here we report the safety profile of IBER+DEX in Cohorts B and D. **Methods:** Patients (pts) received IBER on days (D) 1–21 at a dose range of 0.3–1.6mg (Cohort B) or at 1.6mg (Cohort D) with weekly DEX (40mg; 20mg if >75 years of age) of each 28-day cycle. Following a dose interruption, the IBER dose may be maintained if neutropenia was the only IBER-related toxicity and granulocyte-colony stimulating factor (G-CSF) was used. Primary endpoints were to determine recommended phase 2 dose (Cohort B) and efficacy (Cohort D); safety was a secondary endpoint. Pharmacokinetics (PK) samples were collected on D8, 15, and 22 in cycles 1–4 and a population PK model was developed to estimate IBER PK exposure, which was correlated with efficacy and safety endpoints to assess exposure–response (ER) relationships. **Results:** As of June 2, 2021, 197 pts had received IBER+DEX (90 in Cohort B, 107 in Cohort D). The most frequent grade (Gr) 3/4 TEAEs were neutropenia (38 [42.2%] pts), anemia (24 [26.7%] pts), and infections (23 [25.6%] pts) in Cohort B, and neutropenia (48 [44.9%] pts), anemia (30 [28.0%] pts), and infections (29 [27.1%] pts) in Cohort D. Excluding infections, Gr 3/4 non-hematologic TEAEs were low. Venous thromboembolism occurred in 4 (4.4%) pts in Cohort B and 5 (4.7%) pts in Cohort D. Seventy-four (82.2%) pts in Cohort B and 95 (88.8%) pts in Cohort D experienced at least 1 TEAE related to IBER. Median

onset of neutropenia, anemia, and thrombocytopenia was < 1 mo (both Cohorts); median time to resolution was ≤0.26 mo (Cohort B) and ≤0.46 mo (Cohort D). TEAEs led to IBER dose interruptions in 47 (52.2%) and 56 (52.3%) pts in Cohorts B and D, and dose reductions in 22 (24.4%) and 20 (18.7%) pts in Cohorts B and D, respectively. Epoetin was used in 15 (16.7%) and 13 (12.1%) pts in Cohorts B and D, and G-CSF was used for neutropenia in 33/44 (75.0%) and 40/66 (60.6%) pts in Cohorts B and D, respectively. TEAEs led to IBER discontinuation in 6 (6.7%) and 5 (4.7%) pts in Cohorts B and D; of these, 3 (3.3%) and 1 (0.9%) pt(s) discontinued due to hematologic TEAEs, respectively. ER analysis showed that a higher IBER PK exposure was associated with a higher probability and earlier occurrence of Gr ≥3 neutropenia (P<0.05) and Gr ≥3 thrombocytopenia (P<0.05). **Conclusions:** The all-oral regimen of IBER+DEX showed a tolerable safety profile in pts with RRMM. TEAEs were manageable with dose modifications, dose interruptions, and G-CSF, and few pts discontinued IBER due to TEAEs.

Introduction: In myeloma, t(11;14) confers a unique biology including a lymphoplasmacytic phenotype and an association with plasma cell leukemia. Some studies report a favourable while others a worse prognosis, compared to non-t(11;14) cases. Dependence of t(11;14) cells on the BCL-2 pathway offers a potential therapeutic target. We performed a matched comparison of real-world outcomes in patients with and without t(11;14) as a benchmark for future therapy targeting BCL-2 **Methods:** Using the Canadian Myeloma Research Group Database, we identified patients with a t(11;14) diagnosed from 2004-22. Patients were matched with a non-t(11;14) cohort based on age at line 1 of therapy, gender, year of diagnosis and history of ASCT. Outcomes were examined over the first 4 therapy lines. Differences in baseline characteristics, response, and drug exposure were assessed by McNemar's test and Wilcoxon Signed Rank test. Progression-free (PFS) and overall survival (OS) were calculated by the Kaplan-Meier product-limit method **Results:** 234 t(11;14) patients were matched 1:1 with a non-t(11;14) cohort. Baseline characteristics were similar aside from more patients with light chain myeloma (20.0% vs 8.85%; p < 0.05), hyposecretory/oligosecretory/non-IgA/G subtypes (17.0% vs 7.96%; p< 0.05), and del17p (17.7% vs 7.08%; p< 0.05) in the t(11;14) cohort. Comparing the t(11;14) vs non-t(11;14) groups, the majority of patients received bortezomib-based treatment in line 1 (87.4% vs 84.5%; p=0.767) and 62.8% in each arm underwent ASCT. The most common regimens in line 2 were lenalidomide-based (59.2% vs 77.0%; p=0.24) followed by bortezomib-based treatment (39.8% vs 21.1%; p=0.57). In line 2, daratumumab-based treatment was used in 20.3% vs 30.9% (p< 0.05) respectively. Further regimen details will be presented at the meeting. The median PFS in t(11;14) vs non-t(11;14) patients respectively were 44 vs 46 mo (p< 0.05) after line 1, 18 vs 32 mo (p< 0.05) for line 2, 6 vs 13 mo (p=0.79) for line 3 and 3 vs 6 mo (p=0.83) for line 4 treatment. The median OS in t(11;14) vs non-t(11;14) patients respectively were 99 mo vs 128 mo (p=0.47) after line 1, 77 mo in each cohort (p=0.82) after line 2, 43 vs 26 mo (p=0.44) after line 3 and 34 vs 15 mo after line 4 (p=0.82) **Conclusions:** Compared with non-t(11;14), those with t(11;14) had a shorter PFS in lines 1 and 2. Although not yet translating into a worse OS, this merits longer follow up. The t(11;14) group had more high-risk patients that may account for the shorter PFS. A higher-risk molecular subset with concurrent mutated CCND1 may also be present. The PFS difference was most notable in line 2 where heterogenous immunomodulatory-based therapy was used suggesting a differential effect in t(11;14). Daratumumab use was also higher for non-(11;14) cases in line 2. Our large matched comparison in real-world t(11;14) myeloma serves as an important benchmark for studies looking at targeted BCL-2 inhibitors in these patients.

Introduction: Belantamab mafodotin (belamaf) is an antibody-drug conjugate therapy for myeloma that targets BCMA on malignant plasma cells. Its role in relapsed/refractory myeloma was demonstrated in the DREAMM-2 trial, where it associated with an overall response rate (ORR) of 31% and frequent ocular toxicity – outcomes that have been replicated in retrospective studies across Europe and the USA. Belamaf monotherapy is available in the UK and Ireland through the named-patient programme (NPP), typically as fifth or higher-line therapy and often after disease progression on pomalidomide; however, outcome data for this population are lacking in the literature. **Methods:** We conducted a multicentre retrospective study across the UK and Ireland of patients receiving belamaf monotherapy within the NPP. Belamaf was administered as per the summary of product characteristics, starting at 2.5 mg intravenously every three weeks. Contributors entered data from routine patient notes into a secure online form. Case registration ran from January 2022 to June 2022 (extending to March 2023 for one centre). Data were cleaned in Microsoft Excel and the Tidyverse for R. Analysis was performed on Stata. The primary endpoint was ORR. Secondary end points included progression-free survival (PFS), duration of response (DOR), overall survival (OS) and adverse events (AEs). The Kaplan-Meier method was used for survival analysis. **Results:** 81 patients were registered across thirteen contributing centres. The median age was 65 years (IQR 58 to 72), with 43% female. Median Charlson co-morbidity index was 2. Where data were available, 26% patients had ISS-III and 65% high-risk cytogenetics. Median lines prior therapy was 5 (IQR 4 to 6), with median time from diagnosis to belamaf of 73 months. 70% patients had had prior autologous stem cell transplant. Unexpectedly, 10% were anti-CD38 naïve. At an interim analysis, with median follow-up of 6.6 months and 4 cycles administered (IQR 2 to 6), 48% (n = 39) had discontinued therapy (PD 40%, death 6%, toxicity 1%, unknown 1%). ORR was 56% with at least VGPR in 30%. Median PFS was 9.3 months (95% CI 3.7 to 13.1); median DOR was 15.9 months (4.1 to not reached); and median OS 17.8 months (7.6 to not reached). Data collection for extended survival analysis is ongoing. Toxicity data were available for 76 patients. 83% experienced any grade AE, the most common being keratopathy, infection and thrombocytopenia, affecting 58%, 36% and 20% of patients, respectively. These were also the most frequent ≥ grade 3 AEs; infection affected 30% of patients (with 4% COVID-related deaths), thrombocytopenia 11%, and keratopathy 7%. AE-associated dose delays or reductions occurred in 43% of patients. **Conclusions:** We report an ORR of 56% in our cohort of UK and Ireland patients receiving belamaf monotherapy under the NPP. We will present at the meeting extended follow-up results and an analysis across clinically relevant covariates to compare these outcomes with other studies of belamaf monotherapy.

P-323

A Phase 3 randomized, open-label trial of selinexor, pomalidomide, and dexamethasone versus elotuzumab, pomalidomide, and dexamethasone in patients with relapsed or refractory multiple myeloma

Katja Weisel[1], Ohad Benur[2], Dane Van Domelen[2], Mario Boccadoro[3], Pieter Sonneveld[4]

Introduction: Trial in progress. Increased use of lenalidomide, proteasome inhibitors (PIs) and anti-CD38 monoclonal antibodies (αCD38 mAbs) in early lines of therapy for multiple myeloma (MM) leaves an unmet need for treatments with different mechanisms of action for patients (pts) who develop relapsed and/or refractory MM (RRMM). Selinexor (S), an oral XPO1 inhibitor, and elotuzumab (Elo), a mAb targeting SLAMF7, have novel mechanisms of action and have been evaluated with pomalidomide and dexamethasone (Pd). Results from the phase 1/2 STOMP (NCT02343042) and XPORT-MM-028 (NCT04414475) trials suggest once weekly (QW) SPd was effective in RRMM at S doses of 40mg (SPd-40) or 60mg (SPd-60). SPd-60 had an overall response rate (ORR) of 65% (13/20) and median progression-free survival (mPFS) of 9.5 months (mos). SPd-40 yielded an ORR of 50% (14/28) and mPFS was not reached after a median follow-up time of 12.2 mo. Hematologic adverse events (AEs) included neutropenia, anemia, and thrombocytopenia. Non-hematologic AEs included nausea, fatigue, and weight decrease, all primarily grades 1-2 in severity, with lower rates in SPd-40. In previous studies, EloPd in pts with at least 2 prior lines of therapy yielded an ORR of 53% and mPFS of 10.3 mos. While there are no known prospective randomized studies of EloPd in pts who previously received an aCD38mAb, retrospective studies have reported reduced efficacy. **Methods:** Study design: A Phase 3 randomized, open-label, multicenter trial (NCT05028348) of SPd versus EloPd in pts with RRMM. Select eligibility includes 1-4 prior lines of therapy, including lenalidomide, a PI, and treatment with a regimen that included an αCD38 mAb in the immediate prior line of therapy, but naïve to P, S, and Elo. Randomization stratification factors include number of prior lines, Revised International Staging System (R-ISS) stage, and triple-class refractoriness. The primary objective is to compare the PFS of SPd vs EloPd. The trial consists of two parts. Part 1 assessed the safety and tolerability of S (40 or 60 mg QW) with P (4mg QD on days 1-21) + d (40mg QW) or Elo with Pd to determine the optimal S dose for Part 2. As the study was ongoing, updated data from STOMP and XPORT-MM-028 indicated SPd-40 showed generally comparable efficacy to SPd-60 but with lower AE rates. Thus, SPd-40 was identified as the dose for Part 2. In part 2, ~222 pts will be randomized 1:1 to SPd-40 or EloPd (both administered in 28-day cycles). All pts in the SPd-40 arm will receive dual anti-emetic prophylaxis, such as a 5-HT3 antagonist and olanzapine. Assuming mPFS of 8 mos for SPd vs. 4.8 mos for EloPd (hazard ratio = 0.6), 138 PFS events will provide 85% power to detect superiority at one-sided alpha = 0.025. Secondary

Introduction: Belantamab mafodotin (belamaf) is an antibody-drug conjugate therapy for myeloma that targets BCMA on malignant plasma cells. Its role in relapsed/refractory myeloma was demonstrated in the DREAMM-2 trial, where it associated with an overall response rate (ORR) of 31% and frequent ocular toxicity – outcomes that have been replicated in retrospective studies across Europe and the USA. Belamaf monotherapy is available in the UK and Ireland through the named-patient programme (NPP), typically as fifth or higher-line therapy and often after disease progression on pomalidomide; however, outcome data for this population are lacking in the literature. **Methods:** We conducted a multicentre retrospective study across the UK and Ireland of patients receiving belamaf monotherapy within the NPP. Belamaf was administered as per the summary of product characteristics, starting at 2.5 mg intravenously every three weeks. Contributors entered data from routine patient notes into a secure online form. Case registration ran from January 2022 to June 2022 (extending to March 2023 for one centre). Data were cleaned in Microsoft Excel and the Tidyverse for R. Analysis was performed on Stata. The primary endpoint was ORR. Secondary end points included progression-free survival (PFS), duration of response (DOR), overall survival (OS) and adverse events (AEs). The Kaplan-Meier method was used for survival analysis. **Results:** 81 patients were registered across thirteen contributing centres. The median age was 65 years (IQR 58 to 72), with 43% female. Median Charlson co-morbidity index was 2. Where data were available, 26% patients had ISS-III and 65% high-risk cytogenetics. Median lines prior therapy was 5 (IQR 4 to 6), with median time from diagnosis to belamaf of 73 months. 70% patients had had prior autologous stem cell transplant. Unexpectedly, 10% were anti-CD38 naïve. At an interim analysis, with median follow-up of 6.6 months and 4 cycles administered (IQR 2 to 6), 48% (n = 39) had discontinued therapy (PD 40%, death 6%, toxicity 1%, unknown 1%). ORR was 56% with at least VGPR in 30%. Median PFS was 9.3 months (95% CI 3.7 to 13.1); median DOR was 15.9 months (4.1 to not reached); and median OS 17.8 months (7.6 to not reached). Data collection for extended survival analysis is ongoing. Toxicity data were available for 76 patients. 83% experienced any grade AE, the most common being keratopathy, infection and thrombocytopenia, affecting 58%, 36% and 20% of patients, respectively. These were also the most frequent ≥ grade 3 AEs; infection affected 30% of patients (with 4% COVID-related deaths), thrombocytopenia 11%, and keratopathy 7%. AE-associated dose delays or reductions occurred in 43% of patients. **Conclusions:** We report an ORR of 56% in our cohort of UK and Ireland patients receiving belamaf monotherapy under the NPP. We will present at the meeting extended follow-up results and an analysis across clinically relevant covariates to compare these outcomes with other studies of belamaf monotherapy.

Introduction: LocoMMotion (NCT04035226) is a prospective observational study assessing effectiveness and safety of real-world standard of care (SOC) treatments (tx) for triple-class exposed (TCE) patients (pts) with relapsed/refractory multiple myeloma (RRMM). Here we report final results from LocoMMotion. **Methods:** Pts were TCE, double refractory to a PI and IMiD or with ≥3 prior lines of therapy (LOT), had documented progressive disease (PD) since last LOT and ECOG PS ≤1. Pt-level data for first tx upon study enrollment (index LOT) and subsequent LOT were collected for 24 months (mo) after first dose of last pt enrolled. Primary endpoint was overall response rate (ORR) by response review committee (RRC) assessment per IMWG response criteria. Secondary endpoints included median progression-free survival (mPFS) by RRC, median overall survival (mOS), and adverse events (AEs). Statistical analyses used descriptive statistics and Kaplan-Meier methods. **Results:** Study period was Aug 2019-Oct 2022 with median follow-up 26.4 mo (95%CI 25.0–28.1). N=248, median age 68 y (range 41–89). At baseline, pts had received median 4 prior LOT (range 2–13), 182 (73.4%) were triple-class refractory, 229 (92.3%) were refractory to last prior LOT, and 160 (64.5%) had prior stem cell transplantation (SCT). 91 unique tx regimens were used in index LOT, 162 pts (65.3%) had ≥3 drugs, 6 (2.4%) had SCT. Median duration of treatment (mDOT) was 4.0 mo (range 0.1–33.6). ORR was 31.9% (95%CI 26.1–38.0); median duration of response was 7.4 mo (95%CI 4.9–11.1), mPFS was 4.6 mo (95%CI 3.9–5.6), mOS was 13.8 mo (95%CI 10.8–17.0). 12- and 24-mo PFS rates were 21.0% (95%CI 15.3–27.3) and 10.5% (95%CI 6.1–16.3), and 12- and 24-mo OS rates were 53.4% (95%CI 46.7–59.6) and 33.7% (95%CI 27.3–40.2). 36 pts (14.5%) did not receive subsequent LOT and remained on index LOT, 78 (31.5%) had only 1 subsequent LOT and 74 (29.8%) had ≥2. mPFS2 (from start of study through subsequent LOT1), by investigator assessment, was 10.8 mo (95%CI 8.4–13.0). 79 different regimens were used in subsequent LOT1 with mDOT 2.8 mo (range < 1–29.7). BCMA-targeted tx use increased from 2.8% in index LOT to 24.2% in subsequent LOT. 86.7% of pts experienced AEs during index LOT, most commonly cytopenias. 13 pts (5.2%) reported a second primary malignancy (index LOT, n=5; after index LOT, n=8). 158 pts (63.7%) died during the study most commonly due to PD (67.7%) and AEs (15.8%). 60 pts (24.2%) died during/after index LOT without starting subsequent LOT; 58.3% due to PD, 30.0% due to AEs. 98 pts (39.5%) died after starting subsequent LOT; 73.5% due to PD, 7.1% due to AEs. **Conclusions:** Final analysis of LocoMMotion shows a lack of well-established real-world SOC txs, rapid disease progression, and poor survival despite the wide range of txs used during the study, including subsequent LOT. These findings highlight a need for new therapeutic options in this population. Data previously presented at the European Hematology Association (EHA) 2023 Hybrid Congress.

At baseline, pts had received median 4 prior LOT (range 2–13), 182 (73.4%) were triple-class refractory, 229 (92.3%) were refractory to last prior LOT, and 160 (64.5%) had prior stem cell transplantation (SCT). 91 unique tx regimens were used in index LOT, 162 pts (65.3%) had ≥3 drugs, 6 (2.4%) had SCT. Median duration of treatment (mDOT) was 4.0 mo (range 0.1–33.6). ORR was 31.9% (95%CI 26.1–38.0); median duration of response was 7.4 mo (95%CI 4.9–11.1), mPFS was 4.6 mo (95%CI 3.9–5.6), mOS was 13.8 mo (95%CI 10.8–17.0). 12- and 24-mo PFS rates were 21.0% (95%CI 15.3–27.3) and 10.5% (95%CI 6.1–16.3), and 12- and 24-mo OS rates were 53.4% (95%CI 46.7–59.6) and 33.7% (95%CI 27.3–40.2). 36 pts (14.5%) did not receive subsequent LOT and remained on index LOT, 78 (31.5%) had only 1 subsequent LOT and 74 (29.8%) had ≥2. mPFS2 (from start of study through subsequent LOT1), by investigator assessment, was 10.8 mo (95%CI 8.4–13.0). 79 different regimens were used in subsequent LOT1 with mDOT 2.8 mo (range < 1–29.7). BCMA-targeted tx use increased from 2.8% in index LOT to 24.2% in subsequent LOT. 86.7% of pts experienced AEs during index LOT, most commonly cytopenias. 13 pts (5.2%) reported a second primary malignancy (index LOT, n=5; after index LOT, n=8). 158 pts (63.7%) died during the study most commonly due to PD (67.7%) and AEs (15.8%). 60 pts (24.2%) died during/after index LOT without starting subsequent LOT; 58.3% due to PD, 30.0% due to AEs. 98 pts (39.5%) died after starting subsequent LOT; 73.5% due to PD, 7.1% due to AEs. **Conclusions:** Final analysis of LocoMMotion shows a lack of well-established real-world SOC txs, rapid disease progression, and poor survival despite the wide range of txs used during the study, including subsequent LOT. These findings highlight a need for new therapeutic options in this population. Data previously presented at the European Hematology Association (EHA) 2023 Hybrid Congress.

Introduction: The prospective, non-interventional, multinational LocoMMotion study (NCT04035226) demonstrated suboptimal outcomes in patients (pts) with TCE RRMM (Mateos, Leukemia 2022; data cut-off, May 21, 2021). As a complement to LocoMMotion, the prospective, non-interventional, multinational MoMMent study (NCT05160584) was recently initiated to assess the evolving SOC in pts with TCE RRMM. We report the first pooled analysis of the LocoMMotion (final) and MoMMent studies (data cut-off, Oct 27, 2022). **Methods:** Data were pooled from LocoMMotion, with median follow-up (mFU) of 26.4 months (mo; range, 0.1–35.0) in 248 pts enrolled Aug 2019–Oct 2020, and MoMMent, with mFU of 5.1 mo (range, 0.4–10.9) in 54 pts enrolled Nov 2021–Jul 2022. Both studies have similar designs; statistical heterogeneity was investigated using Cochran Q and I-square. Eligible pts received ≥3 prior lines of therapy (LOT; LocoMMotion allowed < 3 prior LOT if pts were double refractory to a PI and IMiD), were TCE, had measurable disease and documented progressive disease since their last LOT, and had an ECOG performance status (PS) score of 0 or 1 at screening. All pts provided informed consent. The primary endpoint was overall response rate (ORR), evaluated per IMWG criteria by the same review committee. Continuous variables were summarized using descriptive statistics, and ORR was reported with 95% exact CIs. Time-to-event data were summarized by Kaplan-Meier methods. **Results:** Pooled analysis included 302 pts with a mFU of 24.4 mo (range, 0.1–35.0). At baseline, median age was 69 years (y), 54% of pts were male, 75.7% had an ECOG PS of 1, and median time since diagnosis was 6.3 y. Pts received a median of 4 prior LOT (range, 2–13), 73.5% were triple-class refractory, and 17.9% were penta-drug refractory. Prior exposure to BCMA-targeting therapies was higher in MoMMent vs LocoMMotion (11% vs 5%). Overall, 102 unique regimens were used as SOC, and 63.9% of pts received regimens comprising ≥3 drugs. Belantamab mafodotin (22% vs 3%) and idecabtagene vicleucel (6% vs 0%) were more common in MoMMent vs LocoMMotion. In the pooled analysis, ORR was 30.8% (95% CI, 25.6–36.3), median progression-free survival (mPFS) was 4.9 mo (95% CI, 4.2–5.7), and median overall survival was 13.83 mo (95% CI, 10.8–16.9). In MoMMent, ORR was 25.9% (95% CI, 15.0–39.7) and mPFS was 4.9 mo (95% CI, 3.1–6.3), consistent with the LocoMMotion results. Overall, 264 (87.4%) pts reported ≥1 any grade treatment-emergent adverse event (TEAE), with 187 (61.9%) reporting ≥1 grade ≥3 TEAE. 23 (7.6%) deaths due to TEAEs occurred on study, mostly due to infection (n=15). **Conclusions:** These initial results suggest that outcomes in pts with TCE RRMM remain poor. A high unmet need remains for pts with TCE RRMM, as evidenced by the observation that bispecific antibody and CAR-T cell therapies are not yet widely utilized. Increased adoption of these novel immunotherapies into SOC is key to improving outcomes. Additional MoMMent data at 9.2 mo mFU will be presented.

Genome-wide CRISPR screen identifies SPOP as a modulator of IMiDs sensitivity in multiple myeloma

Lijie Xing[1], Jiye Liu[2], Kenneth Wen[2], Teru Hideshima[2], Kenneth Anderson[3], Zengjun Li[1]

[1]Shandong Cancer Hospital and Institute; [2]Dana-Farber Cancer Institute; [3]LeBow Institute for Myeloma Therapeutics and Jerome Lipper Center for Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts

Introduction: The development of novel agents including immunomodulatory drugs (IMiDs) lenalidomide (Len) and pomalidomide (Pom) has led to improved patient outcomes in multiple myeloma (MM); however, MM patients inevitably experience relapse and drug resistance. The expression level of CRBN, CRBN-binding proteins, and CRL4CRBN ubiquitin ligase is considered to be associated with IMiDs resistance. Clinical studies have shown that MM patients can exhibit IMiDs resistance even without CRBN abnormalities, suggesting the molecular mechanisms of intrinsic resistance to IMiDs are not fully understood. **Methods:** To delineate the molecular mechanisms underlying IMiDs resistance, we performed genome-wide knockout (KO) screening in IMiDs-sensitive MM cells. For in vitro work, we used the MM cell lines MM1S, and H929. We used sgRNA to KO SPOP and BRD4 in MM cells. **Results:** After performing a CRISPR KO screen in MM cells, we discovered that in addition to CRBN and its associated genes, sgRNAs targeting SPOP (speckle-type POZ protein, a speckled zinc finger protein) were highly enriched after treatment with Poma. Importantly, SPOP KO MM cell lines acquire significant resistance to Pom and Len treatment. To examine whether SPOP

[1]Shandong Cancer Hospital and Institute; [2]Dana-Farber Cancer Institute; [3]LeBow Institute for Myeloma Therapeutics and Jerome Lipper Center for Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts

Introduction: The development of novel agents including immunomodulatory drugs (IMiDs) lenalidomide (Len) and pomalidomide (Pom) has led to improved patient outcomes in multiple myeloma (MM); however, MM patients inevitably experience relapse and drug resistance. The expression level of CRBN, CRBN-binding proteins, and CRL4CRBN ubiquitin ligase is considered to be associated with IMiDs resistance. Clinical studies have shown that MM patients can exhibit IMiDs resistance even without CRBN abnormalities, suggesting the molecular mechanisms of intrinsic resistance to IMiDs are not fully understood. **Methods:** To delineate the molecular mechanisms underlying IMiDs resistance, we performed genome-wide knockout (KO) screening in IMiDs-sensitive MM cells. For in vitro work, we used the MM cell lines MM1S, and H929. We used sgRNA to KO SPOP and BRD4 in MM cells. **Results:** After performing a CRISPR KO screen in MM cells, we discovered that in addition to CRBN and its associated genes, sgRNAs targeting SPOP (speckle-type POZ protein, a speckled zinc finger protein) were highly enriched after treatment with Poma. Importantly, SPOP KO MM cell lines acquire significant resistance to Pom and Len treatment. To examine whether SPOP

KO-induced IMiDs resistance was CRBN-pathway dependent, we assessed CRBN and its downstream interacting protein levels. SPOP KO showed no effect on CRBN expression; moreover, IMiDs can still trigger IKZF1 and IKZF3 degradation, associated with the downregulation of IRF4, suggesting that SPOP mediates sensitivity to IMiDs in a mechanism independent of CRBN-IKZF1/3 axis. Compared to plasma cells from normal donors, we found that the expression levels of SPOP were significantly decreased in MGUS patients, smoldering myeloma patients, newly diagnosed MM patients, and refractory relapsed MM patients (p-values: 2.4e-2, 2.0e-4, 9.9e-3, 3.17e-6, respectively). SPOP is the adaptor protein of the Cullin3-RING ubiquitin ligase complex. Therefore, the function of SPOP is determined by the characteristics of the substrates it recruits. We performed immunoprecipitation with overexpressed SPOP in MM cells, followed by mass spectrometry analysis, and identified BRD4 as a candidate protein binding to SPOP in MM, which was confirmed by Co-IP. KO of SPOP upregulated the protein level of BRD4 in MM cells. In SPOP KO MM cells, KO of BRD4 resulted in the restoration of MM cell sensitivity to IMiDs treatment. BRD4 plays a significant role in the development and progression of various tumors. The BRD4 inhibitor JQ1 has been shown to exhibit anti-tumor effects in multiple types of cancer. We found that combination treatment with JQ-1 and IMiDs reversed IMiDs resistance of SPOP KO MM cell lines and primary MM cells from relapsed patients. **Conclusions:** Our data show that SPOP is a CRBN-independent modulator of IMiDs sensitivity by regulating BRD4 and provides the preclinical rationale for combining IMiDs with BRD4 inhibitors to overcome IMiDs resistance and improve patient outcomes.

P-327

Hyposecretory progression pattern indicates inferior survival of multiple myeloma

Jingyu Xu[1], Wenqiang Yan[1], Huishou Fan[2], Lugui Qiu[1], Gang An[1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China; [2]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College

Introduction: Almost all MM patients will eventually progress and relapse either asymptomatically or with end-organ damage. At progression patients always present different features with different levels of M protein and plasma cells in bone marrow (BMPC). Interestingly, some patients who are secretory MM types at diagnosis show higher BMPC percentage but lower M protein when PD. The recognition of this subgroup is still unclear.We evaluated the effect of different progression patterns on the survival according to M protein and BMPC percentage. **Methods:** We analyzed baseline and progression features of 211 patients between January 1, 2013 to June 1, 2021 in our hospital. We classify the PD patterns as 3 groups according to the M protein and clonal PCs in bone marrow: a. hyposecretory progression (HypoP) means > 10% increase of the absolute percentage of BMPCs but serum M-protein increase < 5g/L; b. extramedullary progression (EMP) means appearance of a new extramedullary lesion; c. classic progression (ClaP) means any one or more of the other PD criteria according to IMWG criteria. HRCA is defined as the presence of t (4;14), t (14;16) or del (17p) by FISH. Time from the first relapse to death as overall survival after relapse (rel-OS). **Results:** We retrospectively analyzed 12 patients (5.7%) and 30 (14.2%) patients who met the new definition of HypoP and EMP, respectively, and 169 (80.1%) patients can be classified as ClaP group. Interestingly, different to other 2 groups, female patients shared more percentage (66.7%) and IgA (50.0%) as well as light chain (41.7%) were the two most common M protein types in HypoP group. As for the clinical features, HypoP patients were more likely to suffer from hypercalcemia, renal dysfunction and lower serum M protein level both at diagnosis and progression. Also, there were more percentage patients in EMP (50.0% and 53.3%) and HypoP (41.7% and 66.7%) presenting HRCA both at diagnosis and progression. The median follow-up is 42.9m (7.8-99.7m). Patients in ClaP and EMP groups experienced similar PFS whereas HypoP patients had significantly shorter median PFS (P=0.001, 20.6m vs. 22.8m vs. 12.9m). We also found that compared to ClaP and EMP groups, patients with HypoP feature had inferior median OS (P< 0.001, 68.4m vs. 47.2m vs. 25.9m) and rel-OS (P< 0.001, 31.2m vs. 16.6m vs. 8.9m). Besides, a Cox-regression multivariate analysis showed ISS-III (HR 0.471, 95% CI 0.312-0.712; P=0.001), higher LDH (HR 0.519, 95% CI 0.310-0.869, P=0.04), EMP (HR 0.547, 95% CI 0.331-0.904. P=0.019) and HypoP (HR 0.241, 95% CI 0.107-0.543. P=0.001) were associated with shorter OS. **Conclusions:** In conclusion, our results indicate that the patients at progression presenting increased BMPC but lower M protein are inclined to have aggressive features such as hypercalcemia, renal dysfunction and lower serum M protein level both at diagnosis and progression. Also, the hyposecretory progression pattern is a valuable indicator of inferior survival compared to other progression patterns.

KO-induced IMiDs resistance was CRBN-pathway dependent, we assessed CRBN and its downstream interacting protein levels. SPOP KO showed no effect on CRBN expression; moreover, IMiDs can still trigger IKZF1 and IKZF3 degradation, associated with the downregulation of IRF4, suggesting that SPOP mediates sensitivity to IMiDs in a mechanism independent of CRBN-IKZF1/3 axis. Compared to plasma cells from normal donors, we found that the expression levels of SPOP were significantly decreased in MGUS patients, smoldering myeloma patients, newly diagnosed MM patients, and refractory relapsed MM patients (p-values: 2.4e-2, 2.0e-4, 9.9e-3, 3.17e-6, respectively). SPOP is the adaptor protein of the Cullin3-RING ubiquitin ligase complex. Therefore, the function of SPOP is determined by the characteristics of the substrates it recruits. We performed immunoprecipitation with overexpressed SPOP in MM cells, followed by mass spectrometry analysis, and identified BRD4 as a candidate protein binding to SPOP in MM, which was confirmed by Co-IP. KO of SPOP upregulated the protein level of BRD4 in MM cells. In SPOP KO MM cells, KO of BRD4 resulted in the restoration of MM cell sensitivity to IMiDs treatment. BRD4 plays a significant role in the development and progression of various tumors. The BRD4 inhibitor JQ1 has been shown to exhibit anti-tumor effects in multiple types of cancer. We found that combination treatment with JQ-1 and IMiDs reversed IMiDs resistance of SPOP KO MM cell lines and primary MM cells from relapsed patients. **Conclusions:** Our data show that SPOP is a CRBN-independent modulator of IMiDs sensitivity by regulating BRD4 and provides the preclinical rationale for combining IMiDs with BRD4 inhibitors to overcome IMiDs resistance and improve patient outcomes.

P-327

Hyposecretory progression pattern indicates inferior survival of multiple myeloma

Jingyu Xu[1], Wenqiang Yan[1], Huishou Fan[2], Lugui Qiu[1], Gang An[1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China; [2]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College

Introduction: Almost all MM patients will eventually progress and relapse either asymptomatically or with end-organ damage. At progression patients always present different features with different levels of M protein and plasma cells in bone marrow (BMPC). Interestingly, some patients who are secretory MM types at diagnosis show higher BMPC percentage but lower M protein when PD. The recognition of this subgroup is still unclear.We evaluated the effect of different progression patterns on the survival according to M protein and BMPC percentage. **Methods:** We analyzed baseline and progression features of 211 patients between January 1, 2013 to June 1, 2021 in our hospital. We classify the PD patterns as 3 groups according to the M protein and clonal PCs in bone marrow: a. hyposecretory progression (HypoP) means > 10% increase of the absolute percentage of BMPCs but serum M-protein increase < 5g/L; b. extramedullary progression (EMP) means appearance of a new extramedullary lesion; c. classic progression (ClaP) means any one or more of the other PD criteria according to IMWG criteria. HRCA is defined as the presence of t (4;14), t (14;16) or del (17p) by FISH. Time from the first relapse to death as overall survival after relapse (rel-OS). **Results:** We retrospectively analyzed 12 patients (5.7%) and 30 (14.2%) patients who met the new definition of HypoP and EMP, respectively, and 169 (80.1%) patients can be classified as ClaP group. Interestingly, different to other 2 groups, female patients shared more percentage (66.7%) and IgA (50.0%) as well as light chain (41.7%) were the two most common M protein types in HypoP group. As for the clinical features, HypoP patients were more likely to suffer from hypercalcemia, renal dysfunction and lower serum M protein level both at diagnosis and progression. Also, there were more percentage patients in EMP (50.0% and 53.3%) and HypoP (41.7% and 66.7%) presenting HRCA both at diagnosis and progression. The median follow-up is 42.9m (7.8-99.7m). Patients in ClaP and EMP groups experienced similar PFS whereas HypoP patients had significantly shorter median PFS (P=0.001, 20.6m vs. 22.8m vs. 12.9m). We also found that compared to ClaP and EMP groups, patients with HypoP feature had inferior median OS (P< 0.001, 68.4m vs. 47.2m vs. 25.9m) and rel-OS (P< 0.001, 31.2m vs. 16.6m vs. 8.9m). Besides, a Cox-regression multivariate analysis showed ISS-III (HR 0.471, 95% CI 0.312-0.712; P=0.001), higher LDH (HR 0.519, 95% CI 0.310-0.869, P=0.04), EMP (HR 0.547, 95% CI 0.331-0.904. P=0.019) and HypoP (HR 0.241, 95% CI 0.107-0.543. P=0.001) were associated with shorter OS. **Conclusions:** In conclusion, our results indicate that the patients at progression presenting increased BMPC but lower M protein are inclined to have aggressive features such as hypercalcemia, renal dysfunction and lower serum M protein level both at diagnosis and progression. Also, the hyposecretory progression pattern is a valuable indicator of inferior survival compared to other progression patterns.

Research & Development, Horsham, PA, USA; [11]University of Alabama at Birmingham, Birmingham, AL, USA

Introduction: In MonumenTAL-1 (NCT03399799/NCT04634552), talquetamab, a G protein–coupled receptor family C group 5 member D × CD3 bispecific antibody, had an overall response rate of >71% in TCE pts with RRMM who received ≥3 prior lines of therapy (LOT). To assess the relative effectiveness of both recommended phase 2 doses (RP2Ds) of talquetamab vs RWPC, adjusted comparisons were performed using individual patient-level data from MonumenTAL-1 and the Flatiron Health MM cohort database study (Flatiron). **Methods:** An external control arm for MonumenTAL-1 was created from eligible pts in the Flatiron database (data cut-off [DCO] Aug 2022) who met key MonumenTAL-1 eligibility criteria (N=629 with 1169 eligible LOT). Individual patient-level data from MonumenTAL-1 were included for pts who received subcutaneous (SC) talquetamab 0.4 mg/kg weekly (QW; n=143) and SC talquetamab 0.8 mg/kg every other week (Q2W; n=145) utilizing a Jan 17, 2023 DCO. In the base model, baseline characteristics of prognostic variables (refractory status, cytogenetic risk, International Staging System stage, time to disease progression on last LOT, number of prior LOT, time since diagnosis, age, and hemoglobin) were adjusted using inverse probability of treatment weighting. The full model was adjusted for the base model variables as well as prior stem cell transplant, ECOG performance status, race, sex, and MM type. Efficacy outcomes were progression-free survival (PFS), time to next treatment (TTNT), and overall survival (OS). A weighted Cox proportional hazards model was used to derive hazard ratios (HRs) and 95% CIs for time-to-event endpoints; a weighted Kaplan-Meier method was used to derive median time-to-events. Sensitivity analyses assessed the impact of alternative statistical methods and variable adjustment. **Results:** After weighting, baseline characteristics were balanced across cohorts, with standardized mean differences < 0.2. In the base case analysis, compared with RWPC, pts treated with both RP2Ds of talquetamab had significantly improved PFS (QW: 7.5 vs 4.0 months [mo], HR=0.55, 95% CI 0.44–0.69, P< 0.0001; Q2W: 14.2 vs 4.0 mo, HR=0.40, 95% CI 0.31–0.53, P< 0.0001), TTNT (QW: 9.1 vs 5.1 mo, HR=0.59, 95% CI 0.47–0.74, P< 0.0001; Q2W: 13.3 vs 5.1 mo, HR=0.45, 95% CI 0.35–0.59, P< 0.0001), and OS (QW: not reached vs 16.5 mo, HR=0.56, 95% CI 0.40–0.78, P=0.0007; Q2W: not reached vs 15.9 mo, HR=0.48, 95% CI 0.33–0.70, P=0.0002). The fully adjusted models and sensitivity analyses remained in favor of talquetamab for both RP2Ds, consistent with the base case. **Conclusions:** Both RP2Ds of talquetamab significantly improved effectiveness vs RWPC across all outcomes. These data highlight the potential of talquetamab as an effective treatment option in pts with TCE RRMM and support the rationale of planned prospective trials to compare talquetamab with standard of care regimens in this patient population.

Introduction: Daratumumab (dara), carfilzomib (K), pomalidomide (P), and dexamethasone (d) are established therapies in relapsed multiple myeloma (MM) with activity in 3-drug combinations including: dara Kd; dara Pd; and KPd. The paradigm in MM is moving towards more intensive and well-tolerated combinations to achieve deeper and more durable responses while ensuring tolerability. Quadruplet regimens are now becoming standard in newly diagnosed MM, and we explored a 4-drug regimen in relapsed disease. A phase 2 study of dara KPd with a twice/week schedule of K showed an ORR of 89% in pts with a median of 1 prior line (Derman B et al., Blood Adv 2023). Here we report an ongoing study of dara with weekly KPd (dara wKPd) to improve the schedule and tolerability of this regimen. **Methods:** This phase 2 study (NCT04176718) enrolled pts with relapsed/refractory MM who received at least 1 prior therapy, including both lenalidomide and a proteasome inhibitor. Prior therapy with dara, K, or P was permitted except for K and P given together as last line of therapy. Dara wKPd was given on a 28-day schedule, and dara was given according to the dara Pd schedule. An initial cohort (N=16) received dara 16 mg/kg iv (with 1st dose split over two days); the trial was amended to dara 1800 mg sc. K 56 mg/m^2 iv was given weekly on days 1, 8, 15 for cycles 1-12 and days 1, 15 for cycles 13+; for C1D1, dose was 20 mg/m^2. P 4 mg was given po on days 1-21. Dex 40 mg was given weekly with the dose split over two days. Treatment was until progression or unacceptable toxicity. The primary endpoints were overall response and the safety profile of dara wKPd. Secondary endpoints included PFS. **Results:** We enrolled 44 pts, and accrual is complete. Median age was 66 (range 42-73), and median number of prior lines was 2 (range 1-5). All pts were refractory to their last line of therapy and all had prior lenalidomide and proteasome inhibitor. Prior therapies included: pomalidomide (48%), bortezomib (93%), carfilzomib (16%), ixazomib (43%), daratumumab (9%), auto SCT (34%), and ide-cel (2%). High risk FISH: del 17p (20%); t(14;16) (5%); gain of 1q (45%). Median follow up was 10.9 months. 3 pts came off study due to neutropenia leading to delay in treatment. Overall response rate was 98% (PR 27%, VPGR 50%, CR 20%). Median PFS was 30.9 months (95% CI 30.5-not

Introduction: There exists, as of yet, no genetically engineered mouse model (GEMM) with which to simultaneously investigate multiple genetic perturbations in vivo. This is due to (i) lack of a non-leaky germinal center B cell specific Cre mouse, and (ii) lack of an inducible Cre mouse that can simultaneously induce dysregulation of multiple genes in the adult animal. Many genes of interest in MM are either embryonically lethal or cause other neoplasia development in AID-Cre, KRASG12D mice and in Cγ1-Cre, NRASQ61R mice leading, in the latter, to death prior to overt MM development. For these reasons, studies of MM tumorigenesis in the conditional transgenic mouse have been severely restricted by the "leakiness" of AID-Cre mice and Cγ1-Cre mice currently in use. There is therefore an urgent need for a newer system with which to activate genetic mutations or their expression simultaneously in the germinal-center B-cells only in adult mice. **Methods:** We recently created the brand new AIDCreERT2 +/-, EYFP LSL/-, P53 L/L, KrasG12D LSL/-, cMYCLSL/- (AEY-PKM) mouse model, with germinal center B cell restricted overexpression of KrasG12D and cMYC, along with homozygous deletion of P53. Unlike AID-Cre+/- mice, AIDCreERT2 +/- mice express Cre recombinase under the control of an AID promoter and tamoxifen. **Results:** Mice carrying a combination of these traits developed clonal expansion of clonal CD138+ MM cells in the bone marrow and experienced MGUS and MM as they aged (100% of mice after 6 months of age). These studies are the first demonstration of the driving impact of this combination of genes in MM development. AEY-P(K/Q/V)M mice required only ~5 months to develop MGUS and then MM. By comparing the WGS data from these murine MM cell lines, we found most of them to consist of missense mutations and C to T mutations indicative of the germinal center AID process in these cell lines. Fewer secondary genetic mutations are needed for transformation in AEY-PKM and AEY-PM cells to MM cells in comparation with VK*MYC MM cell lines. We also identified similar common mutations in all four mouse myeloma cells lines, including for example Sp140, which was also found in recently published MM patients' data. In our 10X scRNA seq studies using bone marrow samples from 3 AEY-PM, 3 AEY-PKM, 3 AEY-PQM and 3 AEY-PVM bone marrow cells to identify distinct gene signatures from different immune cell populations. We stratified bone marrow immune cells from MM patients into 19 cell clusters. By means of scRNA seq analysis, we then identified the topmost upregulated and downregulated genes in each immune cell cluster. In combination with 5'BCR and 5'TCR seq, we also verified that all the MM tumor developed from AEY-PM, AEY-PKM, AEY-PQM, and AEY-PVM were IgG1 type. **Conclusions:** Our newly generated third generation AEY-PK/V/QM mice with short latency and high penetrance are feasible for preclinical studies without the need of transplantation avoided potential Graft vs. Host Disease (GVHD) from different mice.

Introduction: Gut microbe alterations are closely related to the tumorigenesis and development of cancers. However, the relationship between gut microbe and drug resistance of multiple myeloma (MM) has not been reported. **Methods:** The feces and serum samples of healthy donors (HD), newly diagnosed MM patients (ND) and relapsed MM patients (RM) come from multiple clinical institutions (License number: 202305359). The 5TGM1 MM mouse models were prepared to examine the effect of nitrogen-recycling bacteria on MM in vivo (License number: D2022058). **Results:** To probe the difference in gut microbe between HD and MM patients, we performed shotgun metagenomic sequencing of fecal samples from a cohort of HD, ND and RM, and found that ND and RM show a significantly higher alpha diversity and Citrobacter freundii (CFr) was significantly enriched in RM. Owing

reached). Grade 3-4 hematologic AEs included neutropenia (64%) and thrombocytopenia (20%). Febrile neutropenia occurred in 5%. Introduction: There exists, as of yet, no genetically engineered mouse model (GEMM) with which to simultaneously investigate multiple genetic perturbations in vivo. This is due to (i) lack of a non-leaky germinal center B cell specific Cre mouse, and (ii) lack of an inducible Cre mouse that can simultaneously induce dysregulation of multiple genes in the adult animal. Many genes of interest in MM are either embryonically lethal or cause other neoplasia development in AID-Cre, KRASG12D mice and in Cγ1-Cre, NRASQ61R mice leading, in the latter, to death prior to overt MM development. For these reasons, studies of MM tumorigenesis in the conditional transgenic mouse have been severely restricted by the "leakiness" of AID-Cre mice and Cγ1-Cre mice currently in use. There is therefore an urgent need for a newer system with which to activate genetic mutations or their expression simultaneously in the germinal-center B-cells only in adult mice. **Methods:** We recently created the brand new AIDCreERT2 +/-, EYFP LSL/-, P53 L/L, KrasG12D LSL/-, cMYCLSL/- (AEY-PKM) mouse model, with germinal center B cell restricted overexpression of KrasG12D and cMYC, along with homozygous deletion of P53. Unlike AID-Cre+/- mice, AIDCreERT2 +/- mice express Cre recombinase under the control of an AID promoter and tamoxifen. **Results:** Mice carrying a combination of these traits developed clonal expansion of clonal CD138+ MM cells in the bone marrow and experienced MGUS and MM as they aged (100% of mice after 6 months of age). These studies are the first demonstration of the driving impact of this combination of genes in MM development. AEY-P(K/Q/V)M mice required only ~5 months to develop MGUS and then MM. By comparing the WGS data from these murine MM cell lines, we found most of them to consist of missense mutations and C to T mutations indicative of the germinal center AID process in these cell lines. Fewer secondary genetic mutations are needed for transformation in AEY-PKM and AEY-PM cells to MM cells in comparation with VK*MYC MM cell lines. We also identified similar common mutations in all four mouse myeloma cells lines, including for example Sp140, which was also found in recently published MM patients' data. In our 10X scRNA seq studies using bone marrow samples from 3 AEY-PM, 3 AEY-PKM, 3 AEY-PQM and 3 AEY-PVM bone marrow cells to identify distinct gene signatures from different immune cell populations. We stratified bone marrow immune cells from MM patients into 19 cell clusters. By means of scRNA seq analysis, we then identified the topmost upregulated and downregulated genes in each immune cell cluster. In combination with 5'BCR and 5'TCR seq, we also verified that all the MM tumor developed from AEY-PM, AEY-PKM, AEY-PQM, and AEY-PVM were IgG1 type. **Conclusions:** Our newly generated third generation AEY-PK/V/QM mice with short latency and high penetrance are feasible for preclinical studies without the need of transplantation avoided potential Graft vs. Host Disease (GVHD) from different mice.

Introduction: Gut microbe alterations are closely related to the tumorigenesis and development of cancers. However, the relationship between gut microbe and drug resistance of multiple myeloma (MM) has not been reported. **Methods:** The feces and serum samples of healthy donors (HD), newly diagnosed MM patients (ND) and relapsed MM patients (RM) come from multiple clinical institutions (License number: 202305359). The 5TGM1 MM mouse models were prepared to examine the effect of nitrogen-recycling bacteria on MM in vivo (License number: D2022058). **Results:** To probe the difference in gut microbe between HD and MM patients, we performed shotgun metagenomic sequencing of fecal samples from a cohort of HD, ND and RM, and found that ND and RM show a significantly higher alpha diversity and Citrobacter freundii (CFr) was significantly enriched in RM. Owing

reached). Grade 3-4 hematologic AEs included neutropenia (64%) and thrombocytopenia (20%). Febrile neutropenia occurred in 5%. Non hematologic AEs (all; grade 3-4) included infections (66%; 7%); fatigue (48%; 7%); dyspnea (41%; 2%); increase in ALT/AST (34%; 11%); heart failure or reduced ejection fraction (7%; 0%). There were no hospitalizations or deaths from COVID19. **Conclusions:** Dara wKPd shows some of the highest response rates (98%) and median PFS (30.9 months) in relapsed/refractory MM. This highlights the efficacy of 4-drug regimens and builds on the established activity of dara, K, and P, with manageable toxicity and convenience of weekly K.

Introduction: There exists, as of yet, no genetically engineered mouse model (GEMM) with which to simultaneously investigate multiple genetic perturbations in vivo. This is due to (i) lack of a non-leaky germinal center B cell specific Cre mouse, and (ii) lack of an inducible Cre mouse that can simultaneously induce dysregulation of multiple genes in the adult animal. Many genes of interest in MM are either embryonically lethal or cause other neoplasia development in AID-Cre, KRASG12D mice and in Cγ1-Cre, NRASQ61R mice leading, in the latter, to death prior to overt MM development. For these reasons, studies of MM tumorigenesis in the conditional transgenic mouse have been severely restricted by the "leakiness" of AID-Cre mice and Cγ1-Cre mice currently in use. There is therefore an urgent need for a newer system with which to activate genetic mutations or their expression simultaneously in the germinal-center B-cells only in adult mice. **Methods:** We recently created the brand new AIDCreERT2 +/-, EYFP LSL/-, P53 L/L, KrasG12D LSL/-, cMYCLSL/- (AEY-PKM) mouse model, with germinal center B cell restricted overexpression of KrasG12D and cMYC, along with homozygous deletion of P53. Unlike AID-Cre+/- mice, AIDCreERT2 +/- mice express Cre recombinase under the control of an AID promoter and tamoxifen. **Results:** Mice carrying a combination of these traits developed clonal expansion of clonal CD138+ MM cells in the bone marrow and experienced MGUS and MM as they aged (100% of mice after 6 months of age). Introduction: Gut microbe alterations are closely related to the tumorigenesis and development of cancers. However, the relationship between gut microbe and drug resistance of multiple myeloma (MM) has not been reported. **Methods:** The feces and serum samples of healthy donors (HD), newly diagnosed MM patients (ND) and relapsed MM patients (RM) come from multiple clinical institutions (License number: 202305359). The 5TGM1 MM mouse models were prepared to examine the effect of nitrogen-recycling bacteria on MM in vivo (License number: D2022058). **Results:** To probe the difference in gut microbe between HD and MM patients, we performed shotgun metagenomic sequencing of fecal samples from a cohort of HD, ND and RM, and found that ND and RM show a significantly higher alpha diversity and Citrobacter freundii (CFr) was significantly enriched in RM. Owing

to CFr is a nitrogen-recycling bacteria, we detected the concentration of NH4+ in MM patient's feces and serum, and found that NH4+ increased significantly in RM, and the relative abundance of CFr was positively correlated with NH4+ in feces and serum of RM. Subsequently, we confirmed that NH4+ can promote the drug resistance of MM cells to bortezomib (BTZ) through in vitro and in vivo experiments. Meanwhile, we constructed a CFr deaminase gene deletion (CFr-KO) strain, and found that CFr produces a large fraction of NH4+ by expressing deaminases, and NH4+ molecules produced in the intestinal tract subsequently enter the circulation and eventually travel to the bone marrow, causing MM cells to become resistant to BTZ. Finally, we treated MM cells with NH4+ and detected the expression of resistance related protein. It was found that NH4+ can upregulate the expression of NEK2, and NH4+ can increase the acetylation of NEK2 and reduce its ubiquitin degradation, thus maintaining its protein stability. SLC12A2 as the key transmembrane transporter that mediates the uptake of NH4+ by MM cells, we discovered that furosemide sodium (Fus) can downregulate the expression of SLC12A2 in MM cells. Fus inhibits NH4+ uptake in MM cells and reduces the BTZ resistance-promoting effects of NH4+ supplementation in vitro and in vivo. Next, we analyzed the effect of Fus treatment in MM patients, finding that the MM patients treated with Fus achieved longer progression-free survival and higher curative effect scores. Finally, to explore additional strategies for tackling drug resistance in MM, we performed single Clostridium butyricum (CBu) and triple probiotic (TPro) transplantation by gavage, and we found that in keeping with the effect of CBu transplantation, TPro, an FDA-approved clinical drug, exhibited consistent efficacy in alleviating BTZ resistance. **Conclusions:** In summary, we identify, for the first time, CFr and NH4+ as key modulators of MM relapse, unveil novel molecular mechanisms for drug resistance in MM patients, and provide new therapeutic strategies for the intervention of MM progression and drug resistance.

Challenge accepted: copy number detection by digitalMLPA on small DNA quantities and low tumour content

Lilit Atanesyan[1], Charlotte Enright[1], Suvi Savola[1]

[1]MRC Holland

Introduction: A novel next-generation sequencing-based MLPA variant – digitalMLPA, allows copy number (CN) analysis of hundreds of genomic loci in a single reaction. SALSA digitalMLPA Probemix D006 Multiple Myeloma)targets 469 genomic loci allowing reliable copy number detection of well characterized CN alterations (CNAs) (1p, 1q, 13q, 17p and hyperdiploidy) as well as of CAR-T cell targets (BCMA, GPRC5D, FcRH5) in DNA samples from multiple myeloma (MM). For an optimal digitalMLPA reaction, 40 ng of sample DNA originating from at least 50% of tumour cells is required, which is typically readily obtainable. However the remaining samples are unable to undergo important CN analysis due to limitations in sample requirements. Our aim is to determine the applicability of SALSA digitalMLPA Probemix D006 Multiple Myeloma for challenging samples, and thus, in this study we have analysed CNAs in cancer cell lines with very low DNA input, as well as low tumour cell content. **Methods:** SALSA digitalMLPA Probemix D006 Multiple Myeloma was used for CN analysis on 16 commercial MM cell line DNA samples. For minimal sample DNA input determination digitalMLPA reactions were performed with 2.5, 5, 10 and 20 ng gDNA from three cell lines. For tumour cell content detection limit analysis, dilution series of 10%, 20%, 30%, 40%, 50% and 75% of the same cell line DNA samples with blood-derived DNA samples from healthy individuals were performed. digitalMLPA reactions were performed with 4 µl sample DNA mixed with a unique barcode solution for sample identification. digitalMLPA probes were hybridized overnight to the target DNA, followed by ligation. Ligated probes were PCR amplified and run on an Illumina NextSeq platform. Commercial blood-derived DNA samples from healthy individuals were used as references for data normalization using Coffalyser digitalMLPA™ software. **Results:** CN losses at 1p21.1-p22.1, 1p12, 13q and GPRC5D, and CN gains at 1q21.1-q23.3 and FCRL5 in NCI-H929 cell line were reliably detected even when 2.5 ng input DNA was used. Similarly, all expected CNAs were correctly identified when using 2.5 ng input DNA in other cell lines too. CNAs in tumour-healthy DNA dilutions series were reliably detected if the abnormality was present in at least 20-30% of the analysed sample given that reference samples show highly reproducible probe ratios. In addition, in all analysed samples with 50% neoplastic cell content and 40 ng input DNA CNAs detected on all target loci were highly correlated with those reported in public databases. **Conclusions:** SALSA digitalMLPA Probemix D006 Multiple Myeloma is well suited for multiplex CNA detection of routinely analysed genomic regions in MM, allowing analysis of samples with limited DNA and tumour cell content. In addition, due to the selection of targeted loci, one reaction of this assay serves multiple purposes – detection of well characterized CNAs in MM, other genomic regions and CAR-T therapy targets.

Multi-omic analysis of multiple myeloma subtypes reveals epigenetic programs of high-risk disease

Benjamin Barwick[1], Doris Powell[1], Robert Chavez[1], April Cook[2], Mark Hamilton[2], George Mulligan[2], Daniel Auclair[3], Karen Conneely[1], Paula Vertino[4], Lawrence Boise[1], Sagar Lonial[1]

[1]Emory University; [2]MMRF; [3]AstraZeneca; [4]University of Rochester Medical Center

Introduction: dentifying the biology of high-risk multiple myeloma (MM) is critical to improving outcomes. Current markers imperfectly identify high-risk disease and there are limited data that integrate genetic, epigenetic, and transcriptional information with outcomes. We generated DNA methylation (DNAm) data on 415 samples from the MMRF CoMMpass study and identify distinct epigenetic programs of high-risk disease. **Methods:** Institutional IRB approval was obtained and DNA from CD138+ enriched cells was used to prepare whole genome bisulfite sequencing libraries.

Sequencing was performed on short-read instruments (Illumina) and aligned to the GRCh38 genome with Bismark. DNAm values were obtained at 5x coverage at 16,374,655 CpGs in 90% of samples with an average coverage of 24x. Data were compared to WGBS from the BluePrint project. CoMMpass samples had 100% matching germline and somatic genetic data and 93% had matching RNA-seq. **Results:** Analysis of newly diagnosed MM samples (N=370/415) showed median DNAm was 45% (23-77%), which was significantly less than 69% in normal plasma cells. MM-specific hypomethylation occurred in large, late-replicating domains of the genome. In contrast, normal plasma cells and other B cell malignancies (CLL), showed no reduction in DNAm at late replicating regions. Cross-sectional analysis of RNA and DNAm in cis found 170,777 loci associated with expression, with most (98%) positively associated with transcription and found in gene bodies. Unsupervised t-SNE analysis of DNAm data grouped samples by expression subtype with the NSD2/MMSET (MS) and Proliferation (PR) subtypes more clearly defined by DNAm than RNA-seq. The MS and PR subtypes had 2,075,489 and 418,474 differentially methylated loci (DML), respectively. However, the MS subtype had more DNAm (92% of DML being higher) whereas the PR subtype had less DNAm (99.95% of DML being lower) as compared to other subtypes. Ablation of NSD2 resulted in reduced DNAm, indicating MS subtype hypermethylation was specific to NSD2 expression and excessive H3K36me2. In contrast, no individual gene could be ascribed to PR subtype hypomethylation, but hypomethylation of these loci were prognostic of outcome and lost DNAm between paired baseline and relapse samples. **Conclusions:** While MM is characterized by a profound loss of DNAm, the DNAm retained in actively transcribed gene bodies suggests a role in expression. MM subtypes have distinct epigenetic programs with the high-risk MS and PR subtypes having divergent epigenetic programs. Higher levels of DNAm in the MS subtype are specific to NSD2 overexpression and may result from excessive H3K36me2 being recognized by the PWWP domains of DNA methyltransferases. Lower levels of DNAm in the PR subtype better defined this subtype than RNA and likely result from the replication-dependent loss of DNAm, suggesting DNAm at these loci serve as a readout of the mitotic clock in MM.

Fluorescence in situ hybridization (FISH) t(11;14) testing practices over time in patients with newly diagnosed multiple myeloma (MM) in the USA in the Flatiron Health database

Linda Baughn[1], Sophia Li[2], Rongrong Wang[2], Faiza Zafar[2], Archibong Yellow-Duke[2], Vivek Chopra[2], Allicia Girvan[3], Shaji Kumar[1]

[1]Mayo Clinic, Rochester, MN, US; [2]Genentech, Inc., South San Francisco, CA, US; [3]AbbVie, Inc. North Chicago, IL, US

Introduction: t(11;14) is an important biomarker of MM prognosis and response to therapy, including the BCL-2 inhibitor venetoclax. As MM management evolves with emerging targeted therapies and risk-stratification measures, FISH testing for t(11;14) is needed. We assessed testing practices in MM to understand biomarker testing trends and equitable practices in the USA using the Flatiron Health database. **Methods:** This retrospective study included patients aged ≥ 18 years, diagnosed with MM as their first and only malignancy in the nationwide Flatiron Health electronic health-record derived, de-identified database, between January 2011–July 2022, with ≥ 2 clinic encounters 6 months after diagnosis. Clinical trial participants were excluded. FISH testing rates at diagnosis (≤ 30 days prior to or 90 days post-diagnosis) were evaluated across three timeframes: start of study period to R-ISS publication (Palumbo et al. 2015) (January 2011–August 2015), R-ISS to updated NCCN guidelines (V.1.2020) which include venetoclax for t(11;14)+ MM (September 2015–May 2020), and updated NCCN guidelines to end of study period (June 2020–July 2022). Time to FISH test from diagnosis was assessed. **Results:** Amongst 12,284 eligible patients, at diagnosis, median (interquartile range [IQR]) age was 70 (61–77) years, 46% were female, and 68.8% (n = 8,451) had a FISH test. Testing rates at diagnosis increased yearly, from 50.1% in 2011 to 75.1% by 2022, and during the three defined timeframes (starting from earliest) were 60.2%, 72.1%, and 74.6% ($p < 0.001$). For FISH tests beyond diagnosis (≤ 30 days prior or any time post-diagnosis), 75% (n = 9,157) had ≥ 1 test and median (IQR) time to test was 13 (4–24) days. Testing rates were similar regardless of care setting (community/academic), race/ethnicity, gender, and socioeconomic status index, but decreased with older age (75 years: 66.3% [n = 2,550/3,845]). All subgroups had a median time from diagnosis to FISH test of < 30 days. Despite 17.8% (n = 1,627/9,157) of tested patients having t(11;14), first treatment choice was not impacted, with similar first-line regimens reported for patients with/without t(11;14). **Conclusions:** FISH testing at diagnosis has increased since 2011 alongside changes in MM management guidelines. Though the Flatiron Health database shows minimal testing disparities, other studies indicate real-world survival imbalances; thus there is still a need to identify and address disparities pre- and post-MM diagnosis.

Small nucleotide, copy number and structural variants cooperate to hijack driver genes in extramedullary progression of myeloma

Nicholas Bingham[1], Jaynish Shah[1], Antonia Reale[1], Daniel Wong[1], Tiffany Khong[1], Sridurga Mithraprabhu[1], Andrew Spencer[1]

[1]Alfred Health-Monash University, Melbourne, VIC, Australia

Introduction: Extramedullary disease (EMD) affects up to 30% of multiple myeloma (MM) patients, predicting poor overall survival due to aggressive disease kinetics and multi-drug resistance. Elucidating EMD genomics may inform targeted treatment approaches. **Methods:** We obtained EMD samples from 15 patients (n=8 fresh and n=7 formalin-fixed, paraffin embedded). Second EMD biopsies were taken in n=3, with n=1 having 3 sequential EMD biopsies. Germline variants were excluded using buccal swab DNA. DNA was extracted using QIAGEN DNeasy kit prior to whole genome sequencing (WGS) (30x; xGen PRISM library preparation; Illumina Novaseq). Bioinformatics identified short

Sequencing was performed on short-read instruments (Illumina) and aligned to the GRCh38 genome with Bismark. DNAm values were obtained at 5x coverage at 16,374,655 CpGs in 90% of samples with an average coverage of 24x. Data were compared to WGBS from the BluePrint project. CoMMpass samples had 100% matching germline and somatic genetic data and 93% had matching RNA-seq. **Results:** Analysis of newly diagnosed MM samples (N=370/415) showed median DNAm was 45% (23-77%), which was significantly less than 69% in normal plasma cells. MM-specific hypomethylation occurred in large, late-replicating domains of the genome. In contrast, normal plasma cells and other B cell malignancies (CLL), showed no reduction in DNAm at late replicating regions. Cross-sectional analysis of RNA and DNAm in cis found 170,777 loci associated with expression, with most (98%) positively associated with transcription and found in gene bodies. Unsupervised t-SNE analysis of DNAm data grouped samples by expression subtype with the NSD2/MMSET (MS) and Proliferation (PR) subtypes more clearly defined by DNAm than RNA-seq. The MS and PR subtypes had 2,075,489 and 418,474 differentially methylated loci (DML), respectively. However, the MS subtype had more DNAm (92% of DML being higher) whereas the PR subtype had less DNAm (99.95% of DML being lower) as compared to other subtypes. Ablation of NSD2 resulted in reduced DNAm, indicating MS subtype hypermethylation was specific to NSD2 expression and excessive H3K36me2. In contrast, no individual gene could be ascribed to PR subtype hypomethylation, but hypomethylation of these loci were prognostic of outcome and lost DNAm between paired baseline and relapse samples. **Conclusions:** While MM is characterized by a profound loss of DNAm, the DNAm retained in actively transcribed gene bodies suggests a role in expression. MM subtypes have distinct epigenetic programs with the high-risk MS and PR subtypes having divergent epigenetic programs. Higher levels of DNAm in the MS subtype are specific to NSD2 overexpression and may result from excessive H3K36me2 being recognized by the PWWP domains of DNA methyltransferases. Lower levels of DNAm in the PR subtype better defined this subtype than RNA and likely result from the replication-dependent loss of DNAm, suggesting DNAm at these loci serve as a readout of the mitotic clock in MM.

Introduction: Extramedullary disease (EMD) affects up to 30% of multiple myeloma (MM) patients, predicting poor overall survival due to aggressive disease kinetics and multi-drug resistance. Elucidating EMD genomics may inform targeted treatment approaches. **Methods:** We obtained EMD samples from 15 patients (n=8 fresh and n=7 formalin-fixed, paraffin embedded). Second EMD biopsies were taken in n=3, with n=1 having 3 sequential EMD biopsies. Germline variants were excluded using buccal swab DNA. DNA was extracted using QIAGEN DNeasy kit prior to whole genome sequencing (WGS) (30x; xGen PRISM library preparation; Illumina Novaseq). Bioinformatics identified short

nucleotide variants (SNVs), copy number variations (CNVs) and structural variants (SV) using the Broad Institute GATK best practice pipeline, CNVpytor and Manta, respectively. Droplet digital PCR was used to confirm SNV and CNV findings. **Results:** The median age at diagnosis of MM was 52 years (n=4 primary EMD, n=11 secondary EMD). 46% were hyperdiploid. Driver mutations (DM) in the MAPK pathway were seen in 80%, primarily at codon 61 of NRAS and KRAS (n=5, n=3); only two non-p.Q61 mutations were seen (NRAS p.G13R and KRAS p.A146V). Three patients had activating BRAF mutations (two p.V600E, one p.G469A). Variant allele frequencies (VAF) of DM suggested clonal rather than subclonal level. A quarter of patients (26.6%) had loss of function TP53 mutations. In those with no MAPK DM identified, the median whole genome SNV was 77,142 with a tumour mutational burden (TMB) of 15 mutations/Mb, compared to 20,543 and 3.2 in DM patients. The median SNV and TMB increased with relapse or progression of EMD.CNV/SV analysis identified gain(3q), gain(1q), del(1p) and monosomy 13/ del(13q) in 93%, 86%, 46% and 73% respectively. Gains of BRAF (66%) and MYC (53%) and loss of TP53 (40%) were frequent; with SNV, 20% had biallelic loss. Secondary translocations were seen in 40% of patients, involving MYC, FGFR3, CCND2 and CCND3 in 20%, 13%, 6% and 6%, respectively, and partnered with IGH, IGL and TXNDC5. There was a median of 44 SV per patient. The majority of SV had not been previously identified in these patients and frequently involved published MM driver genes or known super-enhancers such as H1FX. Sequential biopsies of EMD demonstrated temporospatial persistence of DM, with the same DM detected at different anatomical sites and at separate timepoints. There were increased numbers of CNV/SV with relapsed EMD after therapy, consistent with a role in disease progression and drug resistance. **Conclusions:** The MAPK DM, high TMB and persistent genomic instability suggest roles for MAPK-targeted therapies, immunotherapies and DNA damage repair pathway inhibitors, respectively, in EMD. Recurrent codon 61 mutations in RAS suggest a specific role in EMD progression.

Introduction: Multiple myeloma (MM) is a bone marrow (BM) plasma cell malignancy. The tumor microenvironment (TME) contains cellular components as well as the non-cellular extracellular matrix (ECM). Previous research has shown that the expression level of the genes involved in the interaction between MM cells and TME is associated with patient survival. Changes in ECM also contribute to tumor progression and outcomes in patients. In MM, the ECM bidirectionally interacts with MM cells and co-inhabitants of tumor cells or metastatic niches. The oncogenic NOTCH signal has been confirmed to alter TME through contact-dependent signaling between ligands and receptors expressed on MM or stroma cells. However, whether the deregulation of NOTCH signaling affects genes controlling MM to dysregulate ECM integrity, improving clinical prognosis, is still unknown. **Methods:** Here, we applied high-throughput transcriptome profiling to analyze gene expressions that are affected by impairing the NOTCH1 (N1) or NOTCH2 (N2) pathway in different MM cell lines. N1 and N2 knockdown was achieved by transducing corresponding shRNAs in RPMI 8226 and MM.1S cells. **Results:** GO analysis revealed that N1 and N2 regulate core matrisome and matrisome-associated genes, including ECM affiliated protein, regulators, and secreted factors. Gene set enrichment analysis (GSEA) further indicated that both receptors (N1 and N2) control immune system-associated and cytokine activity signatures, such as cytokine receptor binding and inflammatory response in RPMI 8226 cells or leukocyte cell-cell adhesion, toll-like receptor signaling pathway, and chemoattractant activity in MM.1S cells. Moreover, N1/N2 depletion regulates genes involved in bone remodeling and resorption e.g., RUNX2 or SPP1. The 64 matrisome genes found to be consistently up- or downregulated under N1/N2 depletion in RPMI 8226 were further evaluated for the relation of ECM gene expression to patient survival in comparison with primary samples from monoclonal gammopathy of undetermined significance (MGUS), smoldering (sMM), untreated MM patients, and BM plasma (BMPC) of healthy donors. We showed that several ECM genes with expression levels related to the overall survival of MM patients are N2-driven targets, suggesting inhibition of NOTCH signaling might improve the clinical outcome in terms of overall survival. **Conclusions:** Taken together, our data show that both NOTCH receptors participate in the transcriptional control of ECM glycoproteins, ECM-affiliated proteins, ECM regulators, and secreted factors that are proven to have prognostic significance in clinical settings. Further studies are required to better understand how changes in NOTCH-driven matrisome-associated proteins promote MM growth and dissemination in the BM niche.

The majority of SV had not been previously identified in these patients and frequently involved published MM driver genes or known super-enhancers such as H1FX. Sequential biopsies of EMD demonstrated temporospatial persistence of DM, with the same DM detected at different anatomical sites and at separate timepoints. There were increased numbers of CNV/SV with relapsed EMD after therapy, consistent with a role in disease progression and drug resistance. **Conclusions:** The MAPK DM, high TMB and persistent genomic instability suggest roles for MAPK-targeted therapies, immunotherapies and DNA damage repair pathway inhibitors, respectively, in EMD. Recurrent codon 61 mutations in RAS suggest a specific role in EMD progression.

Introduction: Multiple myeloma (MM) is a bone marrow (BM) plasma cell malignancy. The tumor microenvironment (TME) contains cellular components as well as the non-cellular extracellular matrix (ECM). Previous research has shown that the expression level of the genes involved in the interaction between MM cells and TME is associated with patient survival. Changes in ECM also contribute to tumor progression and outcomes in patients. In MM, the ECM bidirectionally interacts with MM cells and co-inhabitants of tumor cells or metastatic niches. The oncogenic NOTCH signal has been confirmed to alter TME through contact-dependent signaling between ligands and receptors expressed on MM or stroma cells. However, whether the deregulation of NOTCH signaling affects genes controlling MM to dysregulate ECM integrity, improving clinical prognosis, is still unknown. **Methods:** Here, we applied high-throughput transcriptome profiling to analyze gene expressions that are affected by impairing the NOTCH1 (N1) or NOTCH2 (N2) pathway in different MM cell lines. N1 and N2 knockdown was achieved by transducing corresponding shRNAs in RPMI 8226 and MM.1S cells. **Results:** GO analysis revealed that N1 and N2 regulate core matrisome and matrisome-associated genes, including ECM affiliated protein, regulators, and secreted factors. Gene set enrichment analysis (GSEA) further indicated that both receptors (N1 and N2) control immune system-associated and cytokine activity signatures, such as cytokine receptor binding and inflammatory response in RPMI 8226 cells or leukocyte cell-cell adhesion, toll-like receptor signaling pathway, and chemoattractant activity in MM.1S cells. Moreover, N1/N2 depletion regulates genes involved in bone remodeling and resorption e.g., RUNX2 or SPP1. The 64 matrisome genes found to be consistently up- or downregulated under N1/N2 depletion in RPMI 8226 were further evaluated for the relation of ECM gene expression to patient survival in comparison with primary samples from monoclonal gammopathy of undetermined significance (MGUS), smoldering (sMM), untreated MM patients, and BM plasma (BMPC) of healthy donors. We showed that several ECM genes with expression levels related to the overall survival of MM patients are N2-driven targets, suggesting inhibition of NOTCH signaling might improve the clinical outcome in terms of overall survival. **Conclusions:** Taken together, our data show that both NOTCH receptors participate in the transcriptional control of ECM glycoproteins, ECM-affiliated proteins, ECM regulators, and secreted factors that are proven to have prognostic significance in clinical settings. Further studies are required to better understand how changes in NOTCH-driven matrisome-associated proteins promote MM growth and dissemination in the BM niche.

The germinal center origin and progression of MM is captured by 83 Vk*MYC MM transplantable lines that share overlapping genomic diversity with human disease

Marta Chesi[1], David Coffey[2], Francesco Maura[2], Caleb Stein[1], Leif Bergsagel[1]

[1]Mayo Clinic Arizona; [2]University of Miami

Introduction: Multiple myeloma (MM) originates from a B cell undergoing B-cell receptor affinity maturation in the germinal center. Errors during class switch recombination and ectopic somatic hypermutation generate immunoglobulin (Ig) gene translocations that are presumptive originating events present in the earliest stages of plasma cell neoplasia. Secondary somatic mutations, including MYC rearrangements, NFkB and RAS/mTORC1 pathway activation, contribute to tumor progression and subclonal heterogeneity. Here, we explore the multi-step progression occurring spontaneously in a murine model of MM driven by MYC dysregulation. **Methods:** We performed WGS, WES and RNAseq on 15 de novo, 58 transplantable lines and 25 tumor lines capable of growth in vitro. In established Vk*MYC transplantable lines, the transgene was excised by tamoxifen driven CRE recombinase. **Results:** We confirmed that MYC expression is sufficient to initiate the progression of a benign monoclonal gammopathy, but full malignancy requires additional somatic events that are spontaneously acquired and selected over time in tumors that have undergone significant Ig somatic hypermutation (average 4.6 mutation/100bp). Notably, there is a convergence between mice and men in the signaling pathways dysregulated during tumor progression, although the genomic mechanisms can be species specific. As in human MM, we noted activation of the NFkB pathway in half of the tumors mostly driven by structural rearrangements in Map3k14, including insertional mutagenesis by endogenous retroelements. This is consistent with a key role for NFkB pathway in MM progression, as demonstrated in two recent murine models of MM driven by IKK2 activation. While activation of RAS/MTORC1 in human MM is mostly driven by mutations of N- and K-RAS, unique to the mouse is the complete inactivation of Pten in a third of cases due to deletion and point mutations mediated by a transcription linked mutational process with a preference for thymidine. As in human MM, we detected frequent alteration (one third) of chromatin modifiers, most commonly Kdm6a and Ncor1. Like in human MM, Trp53 inactivation is almost universal in tumors capable of growing in vitro. Similar to human MM, we noted a progressive reduction of Ig transcription with disease progression, ranging from >50% of the transcriptome in early stages to ~1% in cell lines growing in vitro, that inversely correlates with proliferation. Despite the acquisition of these various progression events, the tumors remain dependent of continuous MYC transgene expression, identifying tumor specific vulnerability. **Conclusions:** By forcing progression of monoclonal gammopathy through MYC dysregulation, the Vk*MYC model spontaneously acquires a diverse array of mutations associated with progression in human MM. This genomic diversity is captured in 58 transplantable tumors lines that can be passaged in vivo into immunocompetent non-irradiated, syngeneic C57Bl/6 recipients, and 25 cell lines capable of in vitro growth.

Differential DNA mutation profiles in multiple myeloma patients: implications of PET/CT findings

Hee Jeong Cho[1], Ju-Hyung Kim[1], Donghyeon Lee[2], Dong Won Baek[1], Sang-Kyun Sohn[1], Jong Gwang Kim[1], Joon Ho Moon[1]

[1]Department of Hematology-Oncology, Kyungpook National University Hospital, School of Medicine, Kyungpook National University, Daegu, South Korea; [2]Department of Biomedical Science, Graduate School, Kyungpook National University

Introduction: The presence of focal lesions in positron emission tomography/computed tomography (PET/CT) scans is well-established as a predictive marker in patients with multiple myeloma (MM). However, there is a lack of knowledge regarding the genetic backgrounds of patients with focal lesions in PET/CT. This study aimed to investigate the DNA sequencing analysis in patients with MM and compare the differences in mutation profiles based on PET/CT results. **Methods:** PET/CT results were determined by the number of focal lesions and the presence of diffuse lesions in the skeletal bone, assessed using the Deauville score. Positive PET/CT findings were defined as metabolic uptake higher than the liver background. Targeted DNA sequencing of 80 mutations was performed to analyze MM cells extracted from the bone marrow using next-generation sequencing (NGS). **Results:** Sixteen newly diagnosed MM patients were enrolled in this study. The median age of the patients was 66 years (range: 49-76). Four patients had ISS stage I, six had stage II, and six had stage III. High-risk cytogenetics, including t(4;14), t(14;16), and del(17p), were identified in six patients (37.5%). Additionally, six patients exhibited amp(1q). Eight patients (50.0%) had more than three focal lesions on PET/CT (FL > 3), while five patients (31.2%) showed positive findings for diffuse lesions on PET/CT. Two patients encountered issues with trimming the fastq file, resulting in a final sequencing analysis of 14 patients using the Genome Analysis Tool Kit (GATK). The analysis revealed a total of 152 somatic mutations with an allele frequency (AF) >1%. The top 10 frequently identified genes were KMT2C (57%), NCOR1 (57%), PABPC1 (50%), ATM (36%), RPS3A (36%), EP300 (29%), HUWE1 (29%), TET2 (29%), TP53 (29%), and ACTG1 (21%). Notably, PABPC1 (6/8, 75%) and KMT2C (6/8, 75%) mutations were more common in patients with FL > 3, whereas patients with FL ≤ 3 exhibited a higher frequency of ATM gene (4/6, 67%) mutations. In patients without diffuse lesions, NCOR1 mutations were frequently observed. **Conclusions:** We found that mutation distribution varied according to PET/CT results, with patients exhibiting FL > 3 showing a higher frequency of PABPC1 and KMT2C mutations. Further studies are warranted to gain a better understanding of the genetic background associated with positive PET/CT findings in MM.

Longitudinal genetically detectable minimal residual disease by interphase fluorescence in situ hybridization confers a poor prognosis in multiple myeloma

Jian Cui[1], Tengteng Yu[2], Wenqiang Yan[2], Jingyu Xu[2], Jiahui Liu[1], Huishou Fan[1], Lugui Qiu[2], Gang An[2]

[1]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College; [2]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College

Introduction: Deeper depth of response (DpR) after induction therapy, especially gain of negative minimal residual disease (MRD), has been linked to prolonged survival in multiple myeloma (MM). However, flow-MRD examination focuses on the numbers, but not on the biological characteristics of residual plasma cells (PCs). To explore whether the genetic features of residual tumor cells affect the survival time of patients with MM, we investigated the clonality of cytogenetic abnormalities (CAs) of the residual PCs using fluorescence in situ hybridization (iFISH) in the National Longitudinal Cohort of Hematological Diseases in China (NCT04645199). **Methods:** A total of 396 patients diagnosed with newly diagnosed MM (NDMM) between January 2014 and March 2020 were included in this study. EDTA-anticoagulated BM aspirate samples were collected at diagnosis for all 396 patients included in this study, and clonal PCs were enriched by CD138+ magnetic beads (Miltenyi Biotec, Paris, France). iFISH was then performed with probes specific for CAs as follows: 13q14, 17p13, 1q21, 14q32 (5'IGH, 3'IGH), t(4;14)(p16;q32), t(11;14)(q13;q32), and t(14;16)(q32;q23), and a total of 200 interphase nuclei were analyzed. **Results:** Persistent CAs after induction therapy were detected in about half of the patients (118/269, 43%), and patients with undetectable CAs showed significantly improved survival compared with those with genetically detectable MRD (median progression-free survival [mPFS]: 59.7 months vs. 35.7 months, P < 0.001; median overall survival [mOS]: 97.1 months vs. 68.8 months, p = 0.011). Additionally, different patterns of therapy-induced clonal evolution were observed by comparing the clonal structure of residual PCs with paired baseline samples. Patients who maintained at high-risk during follow-up had the worst survival (mPFS: 23.0 months; mOS:40.4 months), while those returned to lower risk or had iFISH- at both time points had the best survival (mPFS: 59.7 months; mOS: 97.2 months). **Conclusions:** These foundings highlighted the prognostic value of genetic testing in residual tumor cells after induction therapy, which may provide a deep understanding of clonal evolution and guide the clinical therapeutic strategies.

Minor clone of del(17p) provides a reservoir for relapse in multiple myeloma

Jian Cui[1], Wenqiang Yan[2], Jingyu Xu[2], Jiahui Liu[1], Huishou Fan[1], Lugui Qiu[2], Gang An[2]

[1]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College; [2]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Introduction: As a secondary high-risk cytogenetic abnormality, The deletion of chromosome 17p [del(17p)], especially in high subclonal fraction, is associated with poor prognosis in multiple myeloma. Although del(17p) is detected in approximately 5-10% of newly diagnosed multiple myeloma (NDMM) patients, its prevalence increases to more than 10% in patients at relapse, mainly due to the emergence of new clones with acquired del(17p) during follow-up. However, the impact of del(17p) at relapse on survival at different clonal sizes remains unclear, despite the fact that patients who acquire del(17p) during follow-up have significantly shorter overall survival (OS) compared to controls. Furthermore, the patterns of clonal evolution of del(17p) between diagnosis and relapse and its prognostic value have not been fully understood. **Methods:** The present study was based on the National Longitudinal Cohort of Hematological Diseases in China (NCT04645199). A total of 995 patients in the diagnosis dataset and 293 patients in the relapse dataset have been identified with the required cytogenetic data (tested for chr1q gain, del(17p), del(13q), and IgH rearrangement). Among these patients, 197 had paired iFISH data at diagnosis and first relapse. **Results:** We found a higher frequency of high-risk cytogenetic abnormalities (CAs) and more CAs in MM at relapse than those at diagnosis. Minor clone (present in 10%-50% of malignant PCs) of del(17p) at relapse (hazard ratio = 1.86) but not at diagnosis (hazard ratio = 1.39) was associated with a poor prognosis in MM. Our analysis of paired iFISH results revealed that 56 and 12 patients developed one or more than one new CAs at relapse, with the majority being secondary cytogenetic events, such as del(17p) and gain/amp(1q). We then classified patients into six groups based on the change patterns in clonal size of del(17p) between the two time points. Patients in group A, who experienced the loss of del(17p) at relapse, as well as those in group B, who had a decreasing clonal size from the major to the minor clone at relapse, and those in group C, who did not have del(17p) at both time points, all had similarly superior outcomes (with a second OS of 50.3 months, 16.6 months, and 26.9 months, respectively). In contrast, patients in group D, who newly acquired del(17p) at relapse, had a relatively worse survival (with a second OS of 20.2 months). Of the remaining 16 patients, those with a stable clone of del(17p) between two time points (group E) and those with an obvious increase in clonal size of del(17p) (group F) both had the poorest outcomes (with a second OS of 12.5 months and 12.8 months, respectively). **Conclusions:** In conclusion, our data confirmed the adverse impact of a minor clone

Use of optical genome mapping in the cytogenetic diagnosis of multiple myeloma

Javier de la Rubia[1], Cristian García-Ruiz[2], Díaz-González Álvaro[2], Ana Vicente[3], Mario Arnao[4], María José Cortti[5], Alberto Romero[6], M. Ángeles Escola[7], Esperanza Such[2]

[1]Hematology Department, University Hospital La Fe; [2]Instituto de Investigación Sanitaria La Fe; [3]Hospital Universitario La Fe; [4]Hospital La Fe; [5]Hospital de Manises; [6]Hospital de Maniseshysician; [7]Department of Hematology, Hospital Provincial. Castellón

Introduction: Prognosis of patients with multiple myeloma (MM) is highly heterogeneous. Most of them present genetic alterations and chromosomal abnormalities, with translocations persisting throughout the disease. Cytogenetic studies are usually performed using specific fluorescence in situ hybridization (FISH) probes on selected CD138+ plasma cells. Recently, a new diagnostic technique based on the optical mapping of the genome (Optical Genome Mapping, OGM) is available, which allows the detection of both structural alterations and copy number changes at the whole genome level in a single assay. The main objective of this work was to evaluate and compare OGM performance in total bone marrow (BM) with FISH conducted in selected plasma cells. **Methods:** A total of 10 patients diagnosed with MM were included in this study. All cases were analyzed by FISH on selected CD138+ plasma cells. In parallel, high molecular weight DNA was extracted from total BM, fluorescently marked with the DLE-1 enzyme, and charged in a Shapyr chip for analysis in a Shapyr system (Bionano, San Diego, CA, USA). **Results:** The median age of the patients was 56.5 years old (range, 31–83). Seven were R-ISS stage II and three R-ISS III. Median BM infiltration by plasma cells was 22.5% (range, 6–85%). FISH detected alterations in 8 patients, was negative in 1 patient and non-assessable in 1 case. All patients included in the study were assessable by OGM. In patients #1 and #10, FISH and OGM were concordant, but OGM detected more chromosomal alterations, including multiple losses and gains of material, translocations, and monosomies. Regarding patient #2, with a negative FISH panel, OGM detected multiple CNV and a t(8;18) resulting in a potential TCF4::MYC fusion gene. OGM resolved the case with non-assessable FISH (patient #3) and detected multiple CNV, including a deletion of TP53. Patients #4, #5, #8, and #9 with positive FISH results had a negative result by OGM, likely in the context of low infiltration of plasma cells in BM. Likewise, cases #6 and #7 had a non-concordant result between FISH and OGM, given that OGM did not detect the alterations found by FISH. **Conclusions:** In this study, we analyzed the potential use of OGM in cytogenetic diagnosis of MM using total BM. Our preliminary data suggest that OGM is useful to detect chromosomal alterations and CNV in cases with negative and non-assessable FISH, particularly in patients with high BM infiltration of plasma cells. However, we observed that OGM was negative and non-concordant with FISH for some patients with low plasma cell infiltration and further, refining CD138+ selection will be needed to extend OGM to patients with low BM infiltration.

Introduction: Early intervention for High-Risk Smoldering Multiple Myeloma (HR-SMM) achieves deeper and more prolonged responses compared to newly diagnosed MM (NDMM). It is unclear if this benefit is due to treatment of a less complex entity or inaccuracy in clinical HR-SMM definition. **Methods:** To gain biologic insight into treatment outcomes, we performed the first whole genome sequencing (WGS) analysis of treated HR-SMM for 27 patients treated with carfilzomib, lenalidomide, and dexamethasone (KRd) and R maintenance (NCT01572480). We pooled genomic features with 24 patients with HR-SMM treated with Elotuzumab (Elo)R+/-d; (E-PRISM) and compared to 701 patients with NDMM from CoMMpass. **Results:** After a median follow-up of 24.6 months, median PFS was unreached. After 8 cycles of KRd, 21 (78%) achieved negativity for minimal residual disease (Flow-MRD; LOD 10-5). At 1 year of maintenance, 48% sustained MRD-negativity and 7% lost MRD-negativity. Accrual began in 2012. 3 patients would today be reclassified as MM per 2014 IMWG criteria. One such patient had the only biochemical progression. Otherwise, 11% were HR by Mayo2008 criteria, 52% by Mayo 20/2/20, 67% by PETHEMA, and 78% by RLM criteria (Rajkumar et al. Blood. 2015). 67% met criteria by 2 or more scores and the median 5-year risk of progression per Pangea was 19% (range 5-82). Across pooled HR-SMM, frequency of HR IgH translocations was similar (t(4;14), t(14;16), t(14;20); $p>0.05$) as compared to NDMM from CoMMpass. Driver genes (Rustad et al. Blood Can Disc. 2020) were interrogated together with copy number variation at their loci. Mutations of RAS pathway genes (KRAS, NRAS, and BRAF) were diminished in SMM (22% vs. 48%; $p = < 0.001$), as were gains at the MYC locus (8q24; 6% vs 25%; $p < 0.001$) and gains/amps at 1q (19% vs 33%; $p = 0.039$). Aberrations at key tumor suppressors were less common in HR-SMM ($p < 0.05$): CDKN2C (4 vs 15%), CYLD (8% vs 28%), MAX (8% vs 25.0%), NFKBIA (4% vs 15%), RB1 (20% vs 49%), TENT5C (12% vs 29%), TP53 (4% vs 14%) and TRAF3 (4% vs 20%). There was no biallelic inactivation of TRAF3 as compared to 10% in NDMM ($p = 0.010$).

of del(17p) at relapse and highlighted the importance of designing optimal therapeutic strategies to eliminate high-risk CAs.

Introduction: Prognosis of patients with multiple myeloma (MM) is highly heterogeneous. Most of them present genetic alterations and chromosomal abnormalities, with translocations persisting throughout the disease. Cytogenetic studies are usually performed using specific fluorescence in situ hybridization (FISH) probes on selected CD138+ plasma cells. Recently, a new diagnostic technique based on the optical mapping of the genome (Optical Genome Mapping, OGM) is available, which allows the detection of both structural alterations and copy number changes at the whole genome level in a single assay. The main objective of this work was to evaluate and compare OGM performance in total bone marrow (BM) with FISH conducted in selected plasma cells. **Methods:** A total of 10 patients diagnosed with MM were included in this study. All cases were analyzed by FISH on selected CD138+ plasma cells. In parallel, high molecular weight DNA was extracted from total BM, fluorescently marked with the DLE-1 enzyme, and charged in a Shapyr chip for analysis in a Shapyr system (Bionano, San Diego, CA, USA). **Results:** The median age of the patients was 56.5 years old (range, 31–83). Seven were R-ISS stage II and three R-ISS III. Median BM infiltration by plasma cells was 22.5% (range, 6–85%). FISH detected alterations in 8 patients, was negative in 1 patient and non-assessable in 1 case. All patients included in the study were assessable by OGM. In patients #1 and #10, FISH and OGM were concordant, but OGM detected more chromosomal alterations, including multiple losses and gains of material, translocations, and monosomies. Regarding patient #2, with a negative FISH panel, OGM detected multiple CNV and a t(8;18) resulting in a potential TCF4::MYC fusion gene. OGM resolved the case with non-assessable FISH (patient #3) and detected multiple CNV, including a deletion of TP53. Patients #4, #5, #8, and #9 with positive FISH results had a negative result by OGM, likely in the context of low infiltration of plasma cells in BM. Likewise, cases #6 and #7 had a non-concordant result between FISH and OGM, given that OGM did not detect the alterations found by FISH. **Conclusions:** In this study, we analyzed the potential use of OGM in cytogenetic diagnosis of MM using total BM. Our preliminary data suggest that OGM is useful to detect chromosomal alterations and CNV in cases with negative and non-assessable FISH, particularly in patients with high BM infiltration of plasma cells. However, we observed that OGM was negative and non-concordant with FISH for some patients with low plasma cell infiltration and further, refining CD138+ selection will be needed to extend OGM to patients with low BM infiltration.

Introduction: Early intervention for High-Risk Smoldering Multiple Myeloma (HR-SMM) achieves deeper and more prolonged responses compared to newly diagnosed MM (NDMM). It is unclear if this benefit is due to treatment of a less complex entity or inaccuracy in clinical HR-SMM definition. **Methods:** To gain biologic insight into treatment outcomes, we performed the first whole genome sequencing (WGS) analysis of treated HR-SMM for 27 patients treated with carfilzomib, lenalidomide, and dexamethasone (KRd) and R maintenance (NCT01572480). We pooled genomic features with 24 patients with HR-SMM treated with Elotuzumab (Elo)R+/-d; (E-PRISM) and compared to 701 patients with NDMM from CoMMpass. **Results:** After a median follow-up of 24.6 months, median PFS was unreached. After 8 cycles of KRd, 21 (78%) achieved negativity for minimal residual disease (Flow-MRD; LOD 10-5). At 1 year of maintenance, 48% sustained MRD-negativity and 7% lost MRD-negativity. Accrual began in 2012. 3 patients would today be reclassified as MM per 2014 IMWG criteria. One such patient had the only biochemical progression. Otherwise, 11% were HR by Mayo2008 criteria, 52% by Mayo 20/2/20, 67% by PETHEMA, and 78% by RLM criteria (Rajkumar et al. Blood. 2015). 67% met criteria by 2 or more scores and the median 5-year risk of progression per Pangea was 19% (range 5-82). Across pooled HR-SMM, frequency of HR IgH translocations was similar (t(4;14), t(14;16), t(14;20); $p>0.05$) as compared to NDMM from CoMMpass. Driver genes (Rustad et al. Blood Can Disc. 2020) were interrogated together with copy number variation at their loci. Mutations of RAS pathway genes (KRAS, NRAS, and BRAF) were diminished in SMM (22% vs. 48%; $p = < 0.001$), as were gains at the MYC locus (8q24; 6% vs 25%; $p < 0.001$) and gains/amps at 1q (19% vs 33%; $p = 0.039$). Aberrations at key tumor suppressors were less common in HR-SMM ($p < 0.05$): CDKN2C (4 vs 15%), CYLD (8% vs 28%), MAX (8% vs 25.0%), NFKBIA (4% vs 15%), RB1 (20% vs 49%), TENT5C (12% vs 29%), TP53 (4% vs 14%) and TRAF3 (4% vs 20%). There was no biallelic inactivation of TRAF3 as compared to 10% in NDMM ($p = 0.010$).

In a genome-corrected comparison, APOBEC (SBS2+SBS13) mutational signatures were diminished in KRd WGS compared to 60 dara-KRd-treated NDMM (Maura et al., ASH 2022; 37% vs 87%, p < 0.001) and in E-PRISM vs CoMMpass (17% vs 45%, p = 0.006). Finally, pooling the HR-SMM treated with KRd and Elo-R+/-d, gain/amp1q was associated with a composite of MRD-positivity, loss of MRD-negativity at 1 year, and progressive disease (39% vs 11%; p = 0.047). **Conclusions:** In patients treated on 2 parallel clinical trials for HR-SMM, we found a uniform and relative simplicity in genomic features, which may explain the superior outcomes of contemporary trials. These results support the use of genomics to contextualize advantages of early intervention in SMM (i.e., to avoid overtreatment of non-progressors and to better identify cases likely to progress without therapy).

Evaluation of single nucleotide variants in BRCA1, CDKN1A, TP53BP, and XRCC1 in multiple myeloma patients undergoing hematopoietic stem cell transplantation: association with clinical outcomes

David Garrido[1], Sergio Lopresti[2], Flavia Stella[2], Camila Galvano[3], Ana Inés Catalán[4], Carolina Ottati[4], Ariela Fundia[3], Daniela Lens[4], Irma Slavutsky[3], Eloísa Riva[5]

[1]Hospital de Clínicas Dr. Manuel Quintela; [2]Hospital Prof. Dr. Alejandro Posadas; [3]Institute of Experimental Medicine CONICET-Academia Nacional de Medicina; [4]Departamento Básico de Medicina, Hospital de Clínicas Dr. Manuel Quintela; [5]Hospital Británico. Montevideo, Uruguay

Introduction: High-dose melphalan (HDM) followed by autologous hematopoietic stem cell transplantation (ASCT) remains the standard upfront treatment for transplant-eligible multiple myeloma (MM) patients. However, clinical responses to this strategy are highly variable. We hypothesize that single nucleotide variants (SNVs) in DNA repair genes may influence clinical outcomes in the transplant setting. Aims: To determine the association of SNV in CDKN1A (rs1801270), TP53BP1 (rs560191), BRCA1 (rs4986850, rs1799949, and rs799917), and XRCC1 (rs25487) genes, with the response and progression-free survival (PFS) in patients with MM treated with HDM as pre-transplant conditioning **Methods:** An observational, analytic, and retrospective study, including adult patients with active MM, diagnosed at the Hospital de Clínicas (HC), Uruguay, and Hospital Posadas, Argentina, who received HDM and ASCT as consolidation therapy either frontline or second-line. Evaluated outcomes included response rate and PFS. DNA was purified from peripheral blood or bone marrow. Genotyping of SNVs was performed by conventional PCR and Sanger sequencing. Statistical analysis was performed with SPSS v.26 at p< 0.05. **Results:** We included 34 MM patients with a median age of 53.5 years at diagnosis, 64.7% males, and 35.3% females. The frequency of MM types was 61.8% IgG, 23.6% IgA, and 14.7% light chain myeloma. Risk groups included 26.5% ISS1, 44.1% ISS2, and 29.4% ISS3. Bortezomib-based regimens were used in 97.1%. Six patients received ASCT as second-line consolidation therapy. The median PFS for the whole group was 29.2 months. In patients receiving ASCT as first-line consolidation therapy, a ≥CR after transplantation, and ISS-1 were associated with improved PFS, achieving 48.9 months (p< 0.01) and 54.1 months (p< 0.01), respectively. The frequency of ≥CR before and after ASCT was 26.5% and 52.9%, respectively. The allele frequencies found were rs25487 G 75%, A 25%; rs799917 C 56.4%, T 43.6%; rs4986850 G 89.7%, A 10.3%; rs1799949 G 63.2%, A 36.8%; rs1801270 C 73.5%, A 26.5%; and rs560191 G 77.9%, C 22.1%. No significant differences were found between observed genotype frequencies and those predicted from the Hardy-Weinberg equilibrium. Higher CR rates after the first ASCT were associated with CDKN1A rs1801270 CC (73.3%) and TP53BP1 rs560191 GC/CC (70%) genotypes. Patients with homozygous genotype for BRCA1 rs799917 TT had a significantly lower median PFS compared to CT/CC carriers (p< 0.01) which was similar in patients receiving ASCT only as first-line consolidation (48.9 months vs 16.7 months, p=0.1) **Conclusions:** These preliminary results would indicate that homozygosity for the alternative BRCA1 rs799917 T allele would be associated with treatment failure. To our knowledge, this is the first study evaluating the impact of single nucleotide variants (SNVs) in DNA repair genes in the HDM-ASCT clinical outcomes in Latin America, Further studies are required to validate our results.

Introduction: Extramedullary disease (EMD) is an aggressive manifestation of multiple myeloma (MM), where MM plasma cells (PCs) become independent of the bone marrow (BM) microenvironment and infiltrate other tissues and organs. The incidence of EMD is increasing and is associated with worse prognosis and drug resistance. Unfortunately, the molecular processes underpinning the pathogenesis of extramedullary form of MM that could help better tailor treatment, are poorly understood. Therefore, we performed the most comprehensive multiomics study

In a genome-corrected comparison, APOBEC (SBS2+SBS13) mutational signatures were diminished in KRd WGS compared to 60 dara-KRd-treated NDMM (Maura et al., ASH 2022; 37% vs 87%, p < 0.001) and in E-PRISM vs CoMMpass (17% vs 45%, p = 0.006). Finally, pooling the HR-SMM treated with KRd and Elo-R+/-d, gain/amp1q was associated with a composite of MRD-positivity, loss of MRD-negativity at 1 year, and progressive disease (39% vs 11%; p = 0.047). **Conclusions:** In patients treated on 2 parallel clinical trials for HR-SMM, we found a uniform and relative simplicity in genomic features, which may explain the superior outcomes of contemporary trials. Unfortunately, the molecular processes underpinning the pathogenesis of extramedullary form of MM that could help better tailor treatment, are poorly understood. Therefore, we performed the most comprehensive multiomics study

In a genome-corrected comparison, APOBEC (SBS2+SBS13) mutational signatures were diminished in KRd WGS compared to 60 dara-KRd-treated NDMM (Maura et al., ASH 2022; 37% vs 87%, p < 0.001) and in E-PRISM vs CoMMpass (17% vs 45%, p = 0.006). Finally, pooling the HR-SMM treated with KRd and Elo-R+/-d, gain/amp1q was associated with a composite of MRD-positivity, loss of MRD-negativity at 1 year, and progressive disease (39% vs 11%; p = 0.047). **Conclusions:** In patients treated on 2 parallel clinical trials for HR-SMM, we found a uniform and relative simplicity in genomic features, which may explain the superior outcomes of contemporary trials. These results support the use of genomics to contextualize advantages of early intervention in SMM (i.e., to avoid overtreatment of non-progressors and to better identify cases likely to progress without therapy).

Introduction: High-dose melphalan (HDM) followed by autologous hematopoietic stem cell transplantation (ASCT) remains the standard upfront treatment for transplant-eligible multiple myeloma (MM) patients. However, clinical responses to this strategy are highly variable. We hypothesize that single nucleotide variants (SNVs) in DNA repair genes may influence clinical outcomes in the transplant setting. Aims: To determine the association of SNV in CDKN1A (rs1801270), TP53BP1 (rs560191), BRCA1 (rs4986850, rs1799949, and rs799917), and XRCC1 (rs25487) genes, with the response and progression-free survival (PFS) in patients with MM treated with HDM as pre-transplant conditioning **Methods:** An observational, analytic, and retrospective study, including adult patients with active MM, diagnosed at the Hospital de Clínicas (HC), Uruguay, and Hospital Posadas, Argentina, who received HDM and ASCT as consolidation therapy either frontline or second-line. Evaluated outcomes included response rate and PFS. DNA was purified from peripheral blood or bone marrow. Genotyping of SNVs was performed by conventional PCR and Sanger sequencing. Statistical analysis was performed with SPSS v.26 at p< 0.05. **Results:** We included 34 MM patients with a median age of 53.5 years at diagnosis, 64.7% males, and 35.3% females. The frequency of MM types was 61.8% IgG, 23.6% IgA, and 14.7% light chain myeloma. Risk groups included 26.5% ISS1, 44.1% ISS2, and 29.4% ISS3. Bortezomib-based regimens were used in 97.1%. Six patients received ASCT as second-line consolidation therapy. The median PFS for the whole group was 29.2 months. In patients receiving ASCT as first-line consolidation therapy, a ≥CR after transplantation, and ISS-1 were associated with improved PFS, achieving 48.9 months (p< 0.01) and 54.1 months (p< 0.01), respectively. The frequency of ≥CR before and after ASCT was 26.5% and 52.9%, respectively. The allele frequencies found were rs25487 G 75%, A 25%; rs799917 C 56.4%, T 43.6%; rs4986850 G 89.7%, A 10.3%; rs1799949 G 63.2%, A 36.8%; rs1801270 C 73.5%, A 26.5%; and rs560191 G 77.9%, C 22.1%. No significant differences were found between observed genotype frequencies and those predicted from the Hardy-Weinberg equilibrium. Higher CR rates after the first ASCT were associated with CDKN1A rs1801270 CC (73.3%) and TP53BP1 rs560191 GC/CC (70%) genotypes. Patients with homozygous genotype for BRCA1 rs799917 TT had a significantly lower median PFS compared to CT/CC carriers (p< 0.01) which was similar in patients receiving ASCT only as first-line consolidation (48.9 months vs 16.7 months, p=0.1) **Conclusions:** These preliminary results would indicate that homozygosity for the alternative BRCA1 rs799917 T allele would be associated with treatment failure. To our knowledge, this is the first study evaluating the impact of single nucleotide variants (SNVs) in DNA repair genes in the HDM-ASCT clinical outcomes in Latin America, Further studies are required to validate our results.

Multiomics profiling of extramedullary multiple myeloma tumors and their microenvironment

Tomas Jelinek[1], David Zihala[2,3], Tereza Sevcikova[2,3], Anjana Anilkumar Sithara[2,3,4], Veronika Kapustova[2,3], Hana Sahinbegovic[2,3,4], Ondrej Venglar[2,3,4], Ludmila Muronova[2,3], Lucie Broskevicova[2,3], Daniel Bilek[4], Tereza Popkova[2,3], Hana Plonkova[3], Jan Vrana[2,3], Vladimir Zidlik[5], Pavel Hurnik[5], Martin Havel[6], Matous Hrdinka[2,3], Zuzana Chyra[2,3], Michal Simicek[2,3], Roman Hájek[1,7]

[1]University Hospital Ostrava and University of Ostrava, Ostrava, Czech Republic; [2]Department of Hematooncology, University of Ostrava, Ostrava, Czech Republic; [3]Department of Hematooncology, University Hospital Ostrava, Ostrava, Czech Republic; [4]Faculty of Science, University of Ostrava, Ostrava, Czech Republic; [5]Department of Pathology, University Hospital Ostrava, Ostrava, Czech Republic; [6]Department of Imagining Methods, University Hospital Ostrava, Czech Republic; [7]Faculty of Medicine, Ostrava, Czech Republic

Introduction: Extramedullary disease (EMD) is an aggressive manifestation of multiple myeloma (MM), where MM plasma cells (PCs) become independent of the bone marrow (BM) microenvironment and infiltrate other tissues and organs. The incidence of EMD is increasing and is associated with worse prognosis and drug resistance. Unfortunately, the molecular processes underpinning the pathogenesis of extramedullary form of MM that could help better tailor treatment, are poorly understood. Therefore, we performed the most comprehensive multiomics study

of EMD cells to date combining the whole exome sequencing (WES), bulk RNA sequencing (RNA-seq) and single cell RNA sequencing (scRNA-seq) data from the largest cohort of EMD samples ever sequenced (N=15) collected between 2017-2023. **Methods:** WES was performed for 15 EMD samples and 8 paired NDMM samples using Twist Comprehensive Human Exome. RNAseq was performed for 15 EMD, 8 paired NDMM, 7 unpaired NDMM and 15 unrelated RRMM samples using SMARTer Stranded Total RNA-Seq Kit v2. scRNAseq was performed for 5 EMD samples using Cedhromium 3' library kit. All sequencing was performed on Illumina platform. Only FACS/MACS sorted aberrant PCs were used in case bulk DNA/RNA sequencing. Chromosomal aberrations were evaluated using the combination of FISH and WES. **Results:** We show that combination of genomic lesions 1q21 gain/amplification and at least one mutated gene in MAPK signaling are the most frequent mutations in EMD, present in 14/15 (93%) and 13/15 (87%) EMD samples, respectively. Analyses of bulk RNAseq data showed up-regulation of pathways connected to cell proliferation and upregulation of potent growth factor IL6. Interestingly, CXCR4 gene, important for a homing of plasma cells in bone marrow, was significantly downregulated as well as production of immunoglobulins, with IGL being more prevalent than IGH. We focused on expression of molecular targets for modern immunotherapy, which could be effective in EMD. However, we observed decrease in expression of CD38, GPRC5D, SLAMF7 in EMD cells and lower expression of HLA molecules, which are important for action of immunotherapeutics. Intriguingly, our data suggested novel EMD targets with elevated expression of genes EZH2 and CD70, that are already in use in non-myeloma oncology. In addition, we identified CD8+ T and NK cells as the most abundant immune subsets in EMD microenvironment. **Conclusions:** We performed the largest genomic study of EMD tumors to date and revealed that combination of 1q21 gain/amp and mutations in MAPK pathway are presumably defining genomic features of EMD. Next, transcriptomic profiling of EMD cells suggested high proliferative potential, decreased BM homing, decreased IG production, autocrine growth regulation and decreased expression of some key therapeutically relevant molecules. Finally, for the first time, we dissected the microenvironment of EMD tumors. Overall, our findings represent a significant contribution to understanding of biology and resistance of EMD.

[1]Department of Biostatistics and Health Data Science, School of Medicine, Indiana University; [2]Melvin and Bren Simon Comprehensive Cancer Center, Division of Hematology and Oncology, School of Medicine, Indiana University; [3]Genentech Inc.; [4]Indiana University School of Medicine, Indianapolis, IN, USA

Introduction: Myeloma is a plasma cell malignancy in which a high-risk set of patients can be defined by genomic markers including cytogenetic groups such as loss of 1p, gain or amplification (gain/amp) 1q, and TP53 abnormalities. Increasingly, other markers are also being identified that are associated with progression such as PHF19. **Methods:** Bone marrow aspirates from smoldering multiple myeloma (SMM; n=10), newly diagnosed multiple myeloma (NDMM; n=22), and relapsed/refractory multiple myeloma (RRMM; n=17) patients were collected. Samples underwent CD138+ sorting and single cell multiomic sequencing (RNA-seq and ATAC-seq; 10X Genomics). The multiomic single cell data were integrated using Seurat via weighted nearest neighbors (WNN). Copy number variants (CNVs) were generated using InferCNV. The transcription factor (TF) databases, hTFtarget and TF2DNA were used to identify TFs regulating genes of interest. Previously published paired ChIP-seq and RNA-seq from myeloma cell lines were used to determine TF binding sites. Finally, differences in TF, cell cycle inhibitors, and epigenetic regulator chromatin accessibility and expression in subclones within patient samples with high-risk CNVs were evaluated. **Results:** We previously reported a subset of myeloma cells present primarily in RRMM patients that we denoted relapse/refractory plasma cells (RRPC) that express PHF19 ($P < 0.0001$) and are enriched for amp(1q) ($P < 0.0001$). To determine how PHF19 expression is controlled we examined TF binding sites and identified 92 TFs predicted to bind to the promoter region. Given the association of the RRPCs with amp(1q) we identified seven TF loci encoded on 1q including ZNF648, ATF3, KDM5B, PBX1, RBBP5, RFX5, and USF1 of which PBX1 ($log2FC=0.78$, $P < 0.0001$), RFX5 ($log2FC=0.81$, $P < 0.0001$), and RBBP5 ($log2FC=0.93$, $P < 0.0001$) were significantly up-regulated in RRPCs. ChIP-seq and RNA-seq data were available for PBX1 in MM1S and U266 cell lines, and indicated PBX1 binding at the promoter of PHF19 which was in the top 4% of MM1S ChIP-seq peaks and the top 8% of U266 ChIP-seq peaks. Silencing PBX1 via shRNA significantly decreased PHF19 expression in both cell lines. In our single cell data PBX1 ($log2FC=0.78$, $P < 0.0001$), PHF19 ($log2FC=2.43$ $P < 0.0001$), and FOXM1, a previously identified target of PBX1 in myeloma, ($log2FC=3.64$, $P < 0.0001$) were upregulated in RRPCs. PHF19 expression was detectable in 47% of RRPCs compared to only 9% of cells in other clusters (5.22 fold increase) and PBX1 expression was detectable in 22% of RRPCs compared to only 10% of cells in other clusters (2.44 fold increase). **Conclusions:** Here we show a link between amp(1q), increased expression of the transcription factor PBX1 which leads to increased expression of the high-risk marker PHF19. This link gives further strength and biological meaning to the impact of amp(1q) on high-risk disease.

Internal tandem duplications of the BCMA transmembrane domain are common in hyperdiploid multiple myeloma and associated with constitutive NF-kB signaling

Bryce Turner[1], Daniel Enriquez[1], Christophe Legendre[1], Felix Madrid[1], Shari Kyman[1], Jennifer Rogers[2], George Mulligan[2], Sagar Lonial[3], Jonathan Keats[1,4]

[1]TGen; [2]MMRF; [3]Winship Cancer Institute, Emory University, Atlanta, GA, USA; [4]City of Hope

Introduction: Recent reports have highlighted a number of genetic resistance events in patients who have progressed on BCMA and GPRC5D targeted immunotherapies. We have leveraged the multi-dimensional data in the MMRF CoMMpass study to define the incidence of target allele loss in patients. Moreover, the usage of multiple advanced mutation callers identified recurrent internal tandem duplications (ITD) in TNFRSF17/BCMA reminiscent of the FLT3 ITD seen in AML. **Methods:** Whole genome, exome, and RNA sequencing results from IA22 of the MMRF CoMMpass study were processed through an updated pipeline with alignment to the GRCh38 reference genome. Small variant calling was performed with 5 independent variant callers; Mutect2, Strelka2, Octopus, VarDict, and Lancet. Copy number was determined using GATK CNV with an optimized diploid centering model, structural events were identified using Manta and gene expression estimates were determined using Salmon. **Results:** Integration of the available gene expression, copy number and mutational data facilitated the comprehensive evaluation of the current antibody, bispecific or CAR-T target antigens. At diagnosis all patients expressed the target genes and none had bi-allelic loss of a target loci, however, single copy loss was detected for FCRL5 (0.8%), CD38 (5.6%), GPRC5D (13.2%), and BCMA (3.4%). Four hyperdiploid patients had very high expression of BCMA, which were associated with high level amplifications (5, 12, or 30 copies) or an IgH translocation. High confidence mutation calls (>=3 callers) identified eight patients with SNV or INDEL mutations in BCMA. Two patients had inactivating nonsense or frameshift mutations while the remaining five had large 37-58 nucleotide ITD. Since large insertions are one of the most difficult events to identify we curated the single variant caller results and identified three additional patients with ITD of 46-73 nucleotides. Interestingly, all of these patients have a hyperdiploid karyotype and the ITD occur within the transmembrane domain with a minimal duplication of amino acids 61-66. The ITD are predicted to be gain-of-function events, as each patient was characterized by a high NF-kB gene expression index, exceeding the 90th percentile observed in the cohort in all cases. **Conclusions:** As we begin to prioritize the use of different immune-based therapies it will be important to consider the relative risk each patient has to develop resistance based on the preexisting loss of one target gene copy, as some targets are frequently lost (GPRC5D) while others are rarely lost (FCRL5). Some hyperdiploid patients have hyperactivation of NF-kB signaling as a result of BCMA overexpression by high level copy number gains and immunoglobulin translocations or ITD. These patients are likely dependent on BCMA mediated signaling and would likely be exquisitely sensitive to BCMA targeted therapies. It will be essential to determine if current BCMA directed therapies can still bind these BCMA ITD isoforms.

Longitudinal profiling identifies genetic mechanisms of resistance to four different drug classes in a t(4;14) positive patient

Jonathan Keats[1,2], Azra Borogovac[2], Shari Kyman[1], Jessica Molnar[1], Shukmei Wong[1], Daniel Enriquez[1], Bryce Turner[1], Christophe Legendre[1], Danielle Metz[1], Murali Janakiram[2], Scott Goldsmith[2], Myo Htut[2], Flavia Pichiorri[2], Amrita Krishnan[2]

[1]TGen; [2]City of Hope National Comprehensive Cancer Center

Introduction: Myeloma patients have many therapeutic options available but multiple relapses remains a common scenario. Genomic profiling may help us better understand resistance mechanisms and ultimately select optimal therapies. We present a t(4;14) patient treated with radiation therapy and CyBorD followed by VRd induction, HDT+ASCT, and 27 months of proteasome inhibitor based maintenance therapy (CR). At relapse they received daratumumab based salvage in combination with lenalidomide and then pomalidomide. Subsequent progression was treated with a BCMA directed bispecific with initial sCR but progression occurred seven months later. Subsequent therapy with Isa-Kd resulted in a short PR before progressing two months later and being unresponsive to SVd. The first profiled bone marrow was collected during leukapheresis for cilta-cel but due to progressive disease the patient received an FCRL5 directed bispecific, and a second sample was collected at progression after a brief sCR to this agent. Unfortunately, the patient did not respond to subsequent therapy including a GPRC5D directed bispecific and the stored cilta-cel product. **Methods:** Plasma cells were enriched from bone marrow and peripheral blood using the human CD138+ Positive Selection Kit on an Applied Cells MARS CS Flex Cell Separator. PCR-free short read WGS and mRNA sequencing libraries were sequenced on a NovaSeq 6000. Long-read WGS libraries were sequenced on PromethION R10.4.1 flow cells. **Results:** WGS confirmed the presence of t(4;14), gain(1q21) and del(13q14). Additional events detected included: t(8;22)-IgL::MYC, chromothripsis within and between chromosomes 4 and 17, plus bi-allelic deletions of BCL2L11/BIM, RB1, and CDKN2A/CDKN2B suggesting an apoptosis resistant and proliferative tumor. Therapeutic resistance to anti-CD38 agents and IMiDs started with one copy deletions of CD38 and IKZF3 created by the chromothripsis event. Convergent evolution occurred to inactivate the second CD38 allele with three clones having different interstitial deletions. The second IKZF3 allele was inactivated by a frameshift mutation. This sample also had bi-allelic loss of TNFRSF17/BCMA with eleven different deletions overlapping TNFRSF17/BCMA and a 3 bp deletion in the extracellular domain (Ser30), indicating the presence of multi-clonal resistance. A significant clonal selection was evident in the second timepoint with single inactivation events detected in BIM, CD38, and BCMA. Interestingly, the three copies of FCRL5 detected initially were fully intact even after evaluation with long read sequencing but the expression of FCRL5 was almost undetectable by RNAseq (0.6 TPM) compared to the median seen in the MMRF CoMMpass cohort (243 TPM). **Conclusions:** This case represents the first known bi-allelic loss of CD38 and acquired loss of FCRL5

Introduction: Recent reports have highlighted a number of genetic resistance events in patients who have progressed on BCMA and GPRC5D targeted immunotherapies. We have leveraged the multi-dimensional data in the MMRF CoMMpass study to define the incidence of target allele loss in patients. Moreover, the usage of multiple advanced mutation callers identified recurrent internal tandem duplications (ITD) in TNFRSF17/BCMA reminiscent of the FLT3 ITD seen in AML. **Methods:** Whole genome, exome, and RNA sequencing results from IA22 of the MMRF CoMMpass study were processed through an updated pipeline with alignment to the GRCh38 reference genome. Small variant calling was performed with 5 independent variant callers; Mutect2, Strelka2, Octopus, VarDict, and Lancet. Copy number was determined using GATK CNV with an optimized diploid centering model, structural events were identified using Manta and gene expression estimates were determined using Salmon. **Results:** Integration of the available gene expression, copy number and mutational data facilitated the comprehensive evaluation of the current antibody, bispecific or CAR-T target antigens. At diagnosis all patients expressed the target genes and none had bi-allelic loss of a target loci, however, single copy loss was detected for FCRL5 (0.8%), CD38 (5.6%), GPRC5D (13.2%), and BCMA (3.4%). Four hyperdiploid patients had very high expression of BCMA, which were associated with high level amplifications (5, 12, or 30 copies) or an IgH translocation. High confidence mutation calls (>=3 callers) identified eight patients with SNV or INDEL mutations in BCMA. Two patients had inactivating nonsense or frameshift mutations while the remaining five had large 37-58 nucleotide ITD. Since large insertions are one of the most difficult events to identify we curated the single variant caller results and identified three additional patients with ITD of 46-73 nucleotides. Interestingly, all of these patients have a hyperdiploid karyotype and the ITD occur within the transmembrane domain with a minimal duplication of amino acids 61-66. The ITD are predicted to be gain-of-function events, as each patient was characterized by a high NF-kB gene expression index, exceeding the 90th percentile observed in the cohort in all cases. **Conclusions:** As we begin to prioritize the use of different immune-based therapies it will be important to consider the relative risk each patient has to develop resistance based on the preexisting loss of one target gene copy, as some targets are frequently lost (GPRC5D) while others are rarely lost (FCRL5). Some hyperdiploid patients have hyperactivation of NF-kB signaling as a result of BCMA overexpression by high level copy number gains and immunoglobulin translocations or ITD. These patients are likely dependent on BCMA mediated signaling and would likely be exquisitely sensitive to BCMA targeted therapies. It will be essential to determine if current BCMA directed therapies can still bind these BCMA ITD isoforms.

Introduction: Myeloma patients have many therapeutic options available but multiple relapses remains a common scenario. Genomic profiling may help us better understand resistance mechanisms and ultimately select optimal therapies. We present a t(4;14) patient treated with radiation therapy and CyBorD followed by VRd induction, HDT+ASCT, and 27 months of proteasome inhibitor based maintenance therapy (CR). At relapse they received daratumumab based salvage in combination with lenalidomide and then pomalidomide. Subsequent progression was treated with a BCMA directed bispecific with initial sCR but progression occurred seven months later. Subsequent therapy with Isa-Kd resulted in a short PR before progressing two months later and being unresponsive to SVd. The first profiled bone marrow was collected during leukapheresis for cilta-cel but due to progressive disease the patient received an FCRL5 directed bispecific, and a second sample was collected at progression after a brief sCR to this agent. Unfortunately, the patient did not respond to subsequent therapy including a GPRC5D directed bispecific and the stored cilta-cel product. **Methods:** Plasma cells were enriched from bone marrow and peripheral blood using the human CD138+ Positive Selection Kit on an Applied Cells MARS CS Flex Cell Separator. PCR-free short read WGS and mRNA sequencing libraries were sequenced on a NovaSeq 6000. Long-read WGS libraries were sequenced on PromethION R10.4.1 flow cells. **Results:** WGS confirmed the presence of t(4;14), gain(1q21) and del(13q14). Additional events detected included: t(8;22)-IgL::MYC, chromothripsis within and between chromosomes 4 and 17, plus bi-allelic deletions of BCL2L11/BIM, RB1, and CDKN2A/CDKN2B suggesting an apoptosis resistant and proliferative tumor. Therapeutic resistance to anti-CD38 agents and IMiDs started with one copy deletions of CD38 and IKZF3 created by the chromothripsis event. Convergent evolution occurred to inactivate the second CD38 allele with three clones having different interstitial deletions. The second IKZF3 allele was inactivated by a frameshift mutation. This sample also had bi-allelic loss of TNFRSF17/BCMA with eleven different deletions overlapping TNFRSF17/BCMA and a 3 bp deletion in the extracellular domain (Ser30), indicating the presence of multi-clonal resistance. A significant clonal selection was evident in the second timepoint with single inactivation events detected in BIM, CD38, and BCMA. Interestingly, the three copies of FCRL5 detected initially were fully intact even after evaluation with long read sequencing but the expression of FCRL5 was almost undetectable by RNAseq (0.6 TPM) compared to the median seen in the MMRF CoMMpass cohort (243 TPM). **Conclusions:** This case represents the first known bi-allelic loss of CD38 and acquired loss of FCRL5

expression. These events, along with the loss of BCMA highlight the need for more advanced clinical testing to assess the actionability of the diverse therapeutic targets available to treat patients today.

ADAR1-regulated cytoplasmic dsRNA-immune sensing pathway is a novel mechanism of lenalidomide resistance in multiple myeloma

Mun Yee Koh[1], Tae-Hoon Chung[1], Sabrina Hui Min Toh[1], Nicole Xin Ning Tang[1], Jianbiao Zhou[1], Leilei Chen[1,2], Wee Joo Chng[3], Phaik Ju Teoh[1,4,5]

[1]Cancer Science Institute of Singapore, National University of Singapore; [2]Department of Anatomy, Yong Loo Lin School of Medicine, National University of Singapore; [3]Department of Hematology-Oncology, National University Cancer Institute Singapore, Singapore, Singapore; [4]Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore; [5]Dana-Farber Cancer Institute, Department of Hematology-Oncology, Harvard Medical School, Boston, MA

Introduction: Immunomodulatory drugs (IMiDs) such as lenalidomide and pomalidomide are one of the main cornerstone treatments in multiple myeloma (MM). However, acquired resistance to IMiDs commonly underlies relapse, rendering MM generally incurable. IMiDs bind directly to cereblon (CRBN), the substrate adaptor of the CRL4(CRBN) E3 ubiquitin ligase, and promote the proteasomal degradation of IKZF1 and IKZF3, resulting in MM cell growth inhibition. While resistance to IMiDs has been commonly associated with abnormalities in CRBN and the corresponding factors within the same pathway, the underlying mechanisms in the majority of the cases remain unclear. Adenosine-to-inosine RNA editing, a post-transcriptional modification of dsRNA, catalysed by ADAR1, has shown biological and clinical relevance in MM. ADAR1 is important in the regulation of innate immune response via the dsRNA sensing pathway. Nevertheless, how ADAR1 expression and its aberrant RNA editing could affect cancer immunogenicity and importantly, in regulating IMiDs responses in MM, remain largely unexplored. This study elucidates the role of ADAR1 in mediating MM responses to IMiDs, specifically lenalidomide. **Methods:** A combination of public MM patients' dataset analyses (MMRF CoMMpass, APEX, HOVON, UAMS), generation of isogenic lenalidomide-resistant (LenR) cells and MM models with differential ADAR1 expression were utilised to assess the functional role of ADAR1, its effect in regulating lenalidomide responses in MM and the plausible biological mechanism of actions. **Results:** We observed a close association between ADAR1 expression with lenalidomide sensitivity in a panel of MM cells and in CoMMpass patients' (n=776 len-treated patients of a total of 911), which portends clinical significance. MM cells with ADAR1 knockdown demonstrated enhanced lenalidomide sensitivity, associated with the accumulation of endogenous dsRNAs, activation of the dsRNA-sensing pathways and increased interferon (IFN) responses. Conversely, ADAR1 overexpression reduced lenalidomide sensitivity in an RNA-editing dependent manner, which was observed concomitantly with suppression of the dsRNA-sensing pathway. Assessment of the LenR cells versus len-sensitive revealed higher ADAR1 expression, in association with increased RNA editing frequency, impediment of dsRNAs accumulation and suppression of the dsRNA-sensing pathway. Importantly, we identified the MDA5 as the predominant dsRNA sensor stimulating MM immunogenicity to lenalidomide, with ADAR1 as the upstream regulator. Concordantly, these in vitro findings were supported by our in vivo observations. **Conclusions:** In summary, we identified ADAR1-mediated suppression of dsRNA-sensing pathway as a novel mechanism regulating lenalidomide resistance. Our study harbours crucial translational value as ADAR1 is located at chromosome 1q21 which is frequently amplified in the MM patients. Further studies involve investigating the association of ADAR1 with CRBN pathway.

A retrospective assessment of biologically relevant genomic perturbations and variants of unknown significance in a cohort of plasma cell disorder at our institution; a single center experience

Swarup Kumar[1], Kaylyn Kirk[1], Katharine Hooper[1], Ritika Vankina[1]

[1]UConn Health

Introduction: Significant advances in understanding genomic profiles of plasma cell disorder patients have been made recently. However, the spectrum of genomic variants of uncertain significance (VUS) including their frequency and malignant transformation potential has not been well studied. In our cohort, we assessed the prevalence of biologically relevant variants and VUS using the Tempus xT® platform which is a targeted panel of 648 genes identified by DNA next-generation sequencing (NGS) enriched for clinically relevant and cancer driver genes and genes of emerging or uncertain clinical significance. We also assessed MSigDb (Human Molecular Signatures Database) hallmark gene set pathways that can be impacted by genomic VUS using a web-based tool Enrich R® providing various types of visualization summaries of collective functions of gene lists. **Methods:** Genomic data from bone marrow aspirate samples of sixty-four patients in our institution with monoclonal gammopathies (MGUS), smoldering myeloma (SM), multiple myeloma (MM), AL amyloidosis (AMY) and Waldenstrom's macroglobulinemia (WM) was abstracted using the Tempus xT® NGS platform and compared. Enrich-R® was then used to identify the top 3 Hallmark 2020 MSigDb pathways that were relevant amongst VUS. **Results:** Amongst all patients, 55 biologically relevant mutations and 292 VUS mutations were identified. Twenty-seven of the biologically relevant mutations (49%) were in MM (24/64) with the median number per patient being 1 (0-4). The most frequently observed mutations were that of DNMT3A LOF (6, 22.22%) and KRAS GOF (3, 11.11%). 132 VUS mutations with median of 5 (0-23) mutations per patient were also identified of which KMT2D LOF (5, 3.79%) and NOTCH1 GOF (4, 3.03%) were the most frequently identified. Amongst patients with MGUS (17/64), 6 (12%) biologically relevant mutations were identified whilst 70 VUS mutations with median 4 (1-8) mutations per patient

expression. These events, along with the loss of BCMA highlight the need for more advanced clinical testing to assess the actionability of the diverse therapeutic targets available to treat patients today.

Amongst patients with MGUS (17/64), 6 (12%) biologically relevant mutations were identified whilst 70 VUS mutations with median 4 (1-8) mutations per patient

were also identified. Most frequent VUS were ARID1B LOF (4, 5.71%) and ATM LOF(2, 2.86%). Mean tumor mutational burden (TMB;m/mB) of all disease states was 1.67 in patients with AMY, WM (1.4), and MM (1.32) in comparison to that of MGUS (0.37) and SM (0.23) patients (p 0.08; Mann Whitney U). Identified VUS were input into curated hallmark MSigDb gene sets in EnrichR that identified the following targets in MM patients, E2F Target, G2-M Checkpoint and p53 pathway and in MGUS patents, PI3K/AKT/mTOR signaling, p53 pathway, and Estrogen response late in descending order of importance. **Conclusions:** We herein report the genomic profile of plasma cell disorders using a commercially available assay at the time of diagnosis. Higher TMB and number of VUS per patient trended towards malignant disease states, suggesting that estimation of the known and unknown genomic burden can inform transformation potential. Pathway analysis of VUS genes can also be informative of their biological relevance if truly differentially expressed.

Single cell analysis identifies new insights into the development of venetoclax resistant in multiple myeloma patients

Noemie Leblay[1], Remi Tilmont[1], Mansour Poorebrahim[1], Sungwoo Ahn[1], Ranjan Maity[1], Holly Lee[1], Elie Barakat[1], Benjamin Barwick[2], Lawrence Boise[2], Nizar Bahlis[3], Paola Neri[3]

[1]University of Calgary; [2]Emory University; [3]Arnie Charbonneau Cancer Institute, University of Calgary

Introduction: The BCL2 inhibitor venetoclax has shown promising results in multiple myeloma (MM) patients harboring the t(11;14). However, among these patients the responses are not universal, suggesting that several factors influence its response. We have previously demonstrated that MM cells adapt to its selective pressure by transitioning from B cell-like to a mature plasma cell-like transcriptional and epigenetic signatures. In this study, we used MM primary samples and cell lines to functionally validate some of the key factors involved in venetoclax resistance. **Methods:** Serial BM aspirates were collected from 15 relapsed MM patients; 6 harboring t(11;14) and 9 without the translocation, prior to initiation of therapy and at the time of relapse. All t(11;14) patients were treated with venetoclax. Chromatin accessibility and mRNA profiling of isolated CD138+ MM cells were performed using Chromium Single Cell ATAC and 3' Reagent Kits (10x Genomics) respectively. Pairwise sequencing was performed on NexSeq 500 platform. Cell Ranger, Seurat and ArchR were used for sample demultiplexing, barcode processing, single-cell 3' gene counting and data analysis. Overexpression of MCL1, NOXA, and RUNX1 were induced with lentivirus transduction. **Results:** By comparing the epigenome and transcriptome of pre- and post-venetoclax samples from t(11;14) patients, we identified MCL1 as the major event responsible for venetoclax resistance. As such the overexpression of MCL1 in the venetoclax-sensitive KMS12BM induced resistance to venetoclax through the shifting of BIM loading from BCL2 to MCL1. Furthermore, the MCL1 upregulation was associated with downregulation of the apoptotic sensitizer NOXA and low NOXA/MCL1 ratio. Of interest, ectopic expression of NOXA in the venetoclax-resistant U266 led to loss of MCL1 binding to BIM, confirming the important role of NOXA in priming BCL2 dependency. Furthermore, based on scATAC seq data that showed an enrichment of RUNX1 binding in venetoclax-resistant cells we have decided to overexpress RUNX1 in KMS12BM. As expected, we observed a significant reduction in venetoclax-induced cell death in these cells when compared with WT through downregulation of BCL2. Of note, we also observed an enrichment of RUNX1 binding in non-t(11;14) cells when compared with t(11;14). As such, treatment with the RUNX1 inhibitor AI-10-49 in the non-t(11;14) OPM2 cells resulted in overexpression of NOXA and loss of MCL1 binding to BIM confirming the dual effect of RUNX1 on MCL1 dependence by repressing NOXA and BCL2. **Conclusions:** Taken together these data underline the complexity of the mechanisms involved in venetoclax resistance and showed that the loss of BCL2 dependency can be due to NOXA downregulation and upregulation of MCL-1 and RUNX-1. Therefore, the use of agents that can prime BCL2-dependency through upregulation of NOXA and shifting BIM loading to BCL2 (RUNX1 inhibitors) could be explored in combination with venetoclax in MM patients who acquire MCL1 dependence following treatment.

Introduction: In preclinical CRISPR studies, knockout (KO) of Cereblon (CRBN) or members of its pathway (CRBN-pathway genes, CRBNPGs) are the top perturbations causing MM cell resistance to immunomodulatory thalidomide derivatives (IMiDs), but partial CRBN loss-of-function (LOF) still preserves substantial IMiD responsiveness. Mutations of CRBNPGs were reported in relapses from IMiD±Dex treatment, but it is unclear if they cause complete LOF of CRBNPGs in a way that can explain why MM

were also identified. Most frequent VUS were ARID1B LOF (4, 5.71%) and ATM LOF(2, 2.86%). Mean tumor mutational burden (TMB;m/mB) of all disease states was 1.67 in patients with AMY, WM (1.4), and MM (1.32) in comparison to that of MGUS (0.37) and SM (0.23) patients (p 0.08; Mann Whitney U). Identified VUS were input into curated hallmark MSigDb gene sets in EnrichR that identified the following targets in MM patients, E2F Target, G2-M Checkpoint and p53 pathway and in MGUS patents, PI3K/AKT/mTOR signaling, p53 pathway, and Estrogen response late in descending order of importance. **Conclusions:** We herein report the genomic profile of plasma cell disorders using a commercially available assay at the time of diagnosis. Higher TMB and number of VUS per patient trended towards malignant disease states, suggesting that estimation of the known and unknown genomic burden can inform transformation potential. Pathway analysis of VUS genes can also be informative of their biological relevance if truly differentially expressed.

Introduction: The BCL2 inhibitor venetoclax has shown promising results in multiple myeloma (MM) patients harboring the t(11;14). However, among these patients the responses are not universal, suggesting that several factors influence its response. We have previously demonstrated that MM cells adapt to its selective pressure by transitioning from B cell-like to a mature plasma cell-like transcriptional and epigenetic signatures. In this study, we used MM primary samples and cell lines to functionally validate some of the key factors involved in venetoclax resistance. **Methods:** Serial BM aspirates were collected from 15 relapsed MM patients; 6 harboring t(11;14) and 9 without the translocation, prior to initiation of therapy and at the time of relapse. All t(11;14) patients were treated with venetoclax. Chromatin accessibility and mRNA profiling of isolated CD138+ MM cells were performed using Chromium Single Cell ATAC and 3' Reagent Kits (10x Genomics) respectively. Pairwise sequencing was performed on NexSeq 500 platform. Cell Ranger, Seurat and ArchR were used for sample demultiplexing, barcode processing, single-cell 3' gene counting and data analysis. Overexpression of MCL1, NOXA, and RUNX1 were induced with lentivirus transduction. **Results:** By comparing the epigenome and transcriptome of pre- and post-venetoclax samples from t(11;14) patients, we identified MCL1 as the major event responsible for venetoclax resistance. As such the overexpression of MCL1 in the venetoclax-sensitive KMS12BM induced resistance to venetoclax through the shifting of BIM loading from BCL2 to MCL1. Furthermore, the MCL1 upregulation was associated with downregulation of the apoptotic sensitizer NOXA and low NOXA/MCL1 ratio. Of interest, ectopic expression of NOXA in the venetoclax-resistant U266 led to loss of MCL1 binding to BIM, confirming the important role of NOXA in priming BCL2 dependency. Furthermore, based on scATAC seq data that showed an enrichment of RUNX1 binding in venetoclax-resistant cells we have decided to overexpress RUNX1 in KMS12BM. As expected, we observed a significant reduction in venetoclax-induced cell death in these cells when compared with WT through downregulation of BCL2. Of note, we also observed an enrichment of RUNX1 binding in non-t(11;14) cells when compared with t(11;14). As such, treatment with the RUNX1 inhibitor AI-10-49 in the non-t(11;14) OPM2 cells resulted in overexpression of NOXA and loss of MCL1 binding to BIM confirming the dual effect of RUNX1 on MCL1 dependence by repressing NOXA and BCL2. **Conclusions:** Taken together these data underline the complexity of the mechanisms involved in venetoclax resistance and showed that the loss of BCL2 dependency can be due to NOXA downregulation and upregulation of MCL-1 and RUNX-1. Therefore, the use of agents that can prime BCL2-dependency through upregulation of NOXA and shifting BIM loading to BCL2 (RUNX1 inhibitors) could be explored in combination with venetoclax in MM patients who acquire MCL1 dependence following treatment.

Introduction: In preclinical CRISPR studies, knockout (KO) of Cereblon (CRBN) or members of its pathway (CRBN-pathway genes, CRBNPGs) are the top perturbations causing MM cell resistance to immunomodulatory thalidomide derivatives (IMiDs), but partial CRBN loss-of-function (LOF) still preserves substantial IMiD responsiveness. Mutations of CRBNPGs were reported in relapses from IMiD±Dex treatment, but it is unclear if they cause complete LOF of CRBNPGs in a way that can explain why MM

were also identified. Most frequent VUS were ARID1B LOF (4, 5.71%) and ATM LOF(2, 2.86%). Mean tumor mutational burden (TMB;m/mB) of all disease states was 1.67 in patients with AMY, WM (1.4), and MM (1.32) in comparison to that of MGUS (0.37) and SM (0.23) patients (p 0.08; Mann Whitney U). Identified VUS were input into curated hallmark MSigDb gene sets in EnrichR that identified the following targets in MM patients, E2F Target, G2-M Checkpoint and p53 pathway and in MGUS patents, PI3K/AKT/mTOR signaling, p53 pathway, and Estrogen response late in descending order of importance. **Conclusions:** We herein report the genomic profile of plasma cell disorders using a commercially available assay at the time of diagnosis. Higher TMB and number of VUS per patient trended towards malignant disease states, suggesting that estimation of the known and unknown genomic burden can inform transformation potential. Pathway analysis of VUS genes can also be informative of their biological relevance if truly differentially expressed.

Introduction: In preclinical CRISPR studies, knockout (KO) of Cereblon (CRBN) or members of its pathway (CRBN-pathway genes, CRBNPGs) are the top perturbations causing MM cell resistance to immunomodulatory thalidomide derivatives (IMiDs), but partial CRBN loss-of-function (LOF) still preserves substantial IMiD responsiveness. Mutations of CRBNPGs were reported in relapses from IMiD±Dex treatment, but it is unclear if they cause complete LOF of CRBNPGs in a way that can explain why MM

patients (pts) relapse after IMiD-containing regimens. **Methods:** We evaluated the molecular profiling alterations of 42 CRBNPGs (vs. a set of 42 known MM driver genes; defined by prior studies e.g. Ansari-Pour et al Blood 2023) in pts of the MMRF CoMMpass study (IA22) who had genomic or transcriptional analyses in ≥2 paired bone marrow samples before vs. after IMiD-based treatment (baseline, relapse[s]). **Results:** Among 179 pts fulfilling inclusion criteria, 32 pts (17.9%) had at least one mutated CRBNPG at any timepoint (ptsmut). Of 25 CRBNPGs mutated in any pt, FAM83F was most frequently affected (n=4; 12.5%), followed by CRBN and IKZF3 (n=3 each; 9.4%). 19 pts (59.4%) had a CRBNPG mutation at baseline; 13 pts (40.6%) developed a new CRBNPG mutation at relapse; and 2 pts (6.3%) had >1 mutation (2 and 5 genes). Increase in variant allele frequencies (VAF) of at least one CRBNPG mutation occurred in 14 pts (43.8% of ptsmut), but VAF at relapse were < 0.5. Interestingly, preexisting CRBNPG mutations were not detectable at relapse in 9 pts (28.1%) or had decline in VAF in 3 pts. Clinical response (≥partial response) to IMiDs was documented in 11/13 pts (84.6%) who developed a new CRBNPG mutation and 11/14 pts (78.6%) with VAF increase, while 2 and 3 pts, respectively, had stable or progressive disease. Out of 19 pts with a mutation present at baseline, 2 (10.5%) were non-responsive to IMiD treatment. Importantly, no evidence for complete LOF for any CRBNPG (e.g., via combination of mutation, downregulation/alternative splicing, DNA copy number loss, fusion, etc) was identified at relapse or baseline. Most pts received IMiDs+Proteasome inhibitor (PI), but in our preclinical CRISPR studies, KO of CRBNPGs did not cause sensitization (or resistance) to PIs, thus genomic results for CRBNPGs conceivably were not skewed by PI use, e.g. via elimination of cells with complete LOF of CRBNPGs. In this set of pts, mutations in known MM driver genes (e.g., KRAS, BRAF, ARID1A, TP53, IRF4 among the most frequently affected) were detected at relapse in 26 pts (81.3% of ptsmut) with heterogeneous VAF changes at relapse vs. baseline. **Conclusions:** A minority of MM pts relapsing from IMiD-based treatments harbor genomic defects of CRBNPGs but typically not complete LOF for any such gene, and new/enriched mutations in known MM driver genes cannot be excluded as alternative explanations, beyond CRBNPGs, for these relapses. Additional and more complex, genomic or non-genomic, mechanisms may account for resistance to these regimens.

Enhanced expression of DNp73 promotes drug resistance and immune evasion in multiple myeloma by targeting the MYC and MYCN pathways

Lanting Liu[1], Lixin Gong[1], Hao Sun[1], Lugui Qiu[1], Mu Hao[1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin 300020, China

Introduction: Multiple myeloma (MM) remains an incurable malignancy of plasma cells. The complex bone marrow microenvironment promotes resistance to both current anti-myeloma agents and emerging immunotherapies. Among genomic drivers of the disease, alterations of the tumor suppressor TP53 are associated with poor outcomes. DNp73, an inhibitor of the p53 tumor suppressor family, drives drug resistance and cancer progression in several solid malignancies. However, the biological functions and molecular mechanisms of DNp73 in MM remain unclear. In this study, we investigated the role of DNp73 in the drug resistance of MM, and disclosed the corresponding mechanism of how DNp73 promotes the immune escape of MM cells. **Methods:** We constructed DNp73 overexpression and sh-RNA interference plasmids to obtain stable cell lines. The effects of DNp73 on proliferation and drug sensitivity were determined by flow cytometry and xenotransplantation model. RNA-seq and CHIP-seq were performed to detect the mechanisms of drug resistance in MM cells. The DNA damage repair and invasion ability of MM cells were detected by immunofluorescence and transwell assay. To validate the role of DNp73 in immune escape, we performed phagocytosis assays. **Results:** Our previous study reported that miR-15a was downregulated in MM cells and correlated with the inferior outcome of MM patients. Further analysis demonstrated that DNp73 was a direct target of p65, loss of miR-15a led to the activation of NF-κB-p65 pathway in MM cells. In addition, the level of miR-15a was negatively correlated with the expression of DNp73 in MM cells of patients ($r=-0.672$, $p< 0.05$). After DNp73 was down-regulated, cell proliferation and drug resistance were effectively inhibited. Further in vivo study indicated the tumor volume in DNp73 knockdown group was reduced, and increased sensitivity to the carfilzomib, epirubicin and pomalidomide was observed ($p< 0.01$). Of note, RNA-seq analysis indicated that DNp73 expression was positively correlated with MYCN, MYC and CDK7 transcriptional programs in MM. GSEA analysis showed that MYC targets and DNA damage repair pathways were significantly enriched in DNp73-OE cells. Compared to control group, DNp73-OE cells were resistant to irradiation-induced cell death($p< 0.01$). Meanwhile, DNp73 knockdown significantly reduced the migration and invasion of cells($p< 0.01$). CHIP-seq data showed that DNp73 could bind to the promoter region of MYCN. DNp73 overexpression protects MM cells from phagocytosis, treated with anti-human CD47 antibody increased phagocytosis of macrophages($p< 0.01$). **Conclusions:** In the present study, we demonstrated that miR-15a downregulation activated NF-κB, which promoted DNp73 expression at transcription level. DNp73 is a potential oncogene involved in MM pathogenesis, which promotes MM cells growth and immune evasion by targeting MYC and MYCN pathway.

In vitro functional characterization of a multiple myeloma susceptibility locus

Angelica Macauda[1], Mehrnoosh Shokouhi[1], Rainer Will[1], Romano Liotti[2], Pelin Ünal[1], Jose Manuel Maldonado-Sanchez[1], Federico Canzia[1]

[1]German Cancer Research Center (DKFZ); [2]University of Pisa

Introduction: Several genome-wide association studies (GWAS) have been conducted to identify germline variants predisposing to multiple myeloma (MM). Up to date, 24 loci were found to be associated with MM risk, but very little information is available about their functional role. GWAS design takes advantage of the linkage disequilibrium (LD) structure of the human genome, thus the main GWAS findings are single-nucleotide polymorphisms (SNPs) that show the strongest association with MM risk (measured as the lowest p-values), but they are not necessarily the functionally causal variants. The functional characterization of the causal risk variants would lead to a better understanding of disease development. For these reasons we aimed at exploring in vitro the function of the GWAS-identified rs3747481 SNP through CRISPR-Cass9 knock-in technology in the U266B1 MM cell line. **Methods:** To maximize the probability to capture the casual variant, we focused on chr16 q23.1, the locus with the smallest number of SNPs in high LD (r2>0.8). A cell pool of U266B1 containing the edited locus of interest was generated by the company Synthego (https://www.synthego.com/) with CRISPR-Cas9 knock-in technology. The isogenic cell colonies were then generated using a CloneSelect Single-Cell Printer. Successfully growing colonies with the three possible genotypes at rs3747481 were functionally tested. In particular, we measured: differences in proliferation, migration and gene expression of the nearby gene RNF40. The last test was also performed in 25 MM bone marrow samples with known genotypes at rs3747481. Kruskal-Wallis and T test were used to analyse the statistical significance. **Results:** rs3747481 was of particular functional interest, due to the following reasons: it is a missense variant (protein change: P359L), has a high CADD PHRED score (22.1) and, according to GTEx portal, it is associated with the expression level of the RNF40 gene. We successfully isolated two T/T colonies and one C/T colony for functional testing (T is the MM risk associated allele). A 2.3-fold decrease in proliferation was observed in T/T colonies and 2.9 for colonies with C/T genotype compared to the C/C wild type (p=0.02). The migration assay showed a significant increase in cell migration of 3-fold (p=0.002) for the cells carrying the T allele. A significant increase of the expression of RNF40 was also observed when comparing the 3 genotypes in the cell lines, with the highest expression in T/T cells (p=0.001). A similar difference was observed in the BM patients as well, although not significant. **Conclusions:** We successfully edited the genotypes of interest and observed a decrease in proliferation and an increase in migration in colonies with the MM risk allele, as well as a significant increase in the expression of RNF40. These findings confirmed the functional role of rs3747481. However, further experiments will be needed to better understand the biological mechanism of action of the polymorphism.

Introduction: In the U.S. population, having African ancestry (AA) conveys a higher risk of multiple myeloma (MM) than white ancestry (WA), however, published whole genomic sequencing (WGS) data is predominantly from WA populations. The Polyethnic-1000 (P1000) is a multi-institutional initiative with the New York Genome Center, investigating cancers having a higher prevalence in AA populations. We hypothesize that self-described race and ethnicity, according to limited proscribed categories, are insufficient to delineate biological contribution to MM development. Unique biological insights may require comprehensive definition of genetic origin, considering heterogeneity within historically defined groups. **Methods:** We applied Admixture, a composition profile based on SNPs corresponding to geographical reference populations, to both targeted sequencing (MSK-Heme-IMPACT) and WGS. Admixture estimates proportion per patient from 5 super populations (African [AFR], American [AMR], European [EUR], East Asian, South Asian), with WGS allowing resolution of 23 subpopulations. From patients self-identifying as Black or Hispanic, 111 samples had IMPACT and 101 WGS. Results were compared with the CoMMpass dataset and WA WGS, to a total WGS cohort of 1221. **Results:** Genomic complexity hidden by self-reported race and ethnicity was revealed by genetically determined Admixture. IMPACT data estimated that while 42 (38%) had AFR super family contribution ≥0.9, 37 (33%) had 0.5-0.8 and 32 (29%) had < 0.5. 24% self-identifying as Hispanic had ≥0.5 AFR. From WGS, 46/101 had ≥ 0.25 from at least 2/23 subpopulations (consistent with grandparents) with 94 having ≥0.125 from different subpopulations (consistent with great-grandparents). From those with ≥0.25 from different populations, 33 were within AFR while 11 were across super-populations. Hierarchical clustering analysis of the P1000 samples together with 134 CoMMpass samples having AFR > 0.1 produced 3 main patient clusters; 2 with predominantly AFR ancestry, clustering by proportion of AFR contribution, while 1 cluster was highly admixed with EUR and AMR. Clustering based on subpopulations was highly analogous. Considering the entire WGS cohort produced 6 clusters; 5 had a predominant super population, with the majority of AFR collapsed into 1 cluster, while 1 cluster was heterogenous in composition. Self-described WA patients also had significant admixture revealed. **Conclusions:** Self-reported race and ethnicity don't allow consideration of the significant variability of genetic admixture present in our patients, with likely insufficient granularity on inherited risk of MM. Our genomic datasets could benefit from increasing AA and Hispanic representation. Clustering analysis should consider both the entire cohort and separately analyze non-WA samples, to allow adequate resolution of genetic

Introduction: Several genome-wide association studies (GWAS) have been conducted to identify germline variants predisposing to multiple myeloma (MM). Up to date, 24 loci were found to be associated with MM risk, but very little information is available about their functional role. GWAS design takes advantage of the linkage disequilibrium (LD) structure of the human genome, thus the main GWAS findings are single-nucleotide polymorphisms (SNPs) that show the strongest association with MM risk (measured as the lowest p-values), but they are not necessarily the functionally causal variants. The functional characterization of the causal risk variants would lead to a better understanding of disease development. For these reasons we aimed at exploring in vitro the function of the GWAS-identified rs3747481 SNP through CRISPR-Cass9 knock-in technology in the U266B1 MM cell line. **Methods:** To maximize the probability to capture the casual variant, we focused on chr16 q23.1, the locus with the smallest number of SNPs in high LD (r2>0.8). A cell pool of U266B1 containing the edited locus of interest was generated by the company Synthego (https://www.synthego.com/) with CRISPR-Cas9 knock-in technology. The isogenic cell colonies were then generated using a CloneSelect Single-Cell Printer. Successfully growing colonies with the three possible genotypes at rs3747481 were functionally tested. In particular, we measured: differences in proliferation, migration and gene expression of the nearby gene RNF40. The last test was also performed in 25 MM bone marrow samples with known genotypes at rs3747481. Kruskal-Wallis and T test were used to analyse the statistical significance. **Results:** rs3747481 was of particular functional interest, due to the following reasons: it is a missense variant (protein change: P359L), has a high CADD PHRED score (22.1) and, according to GTEx portal, it is associated with the expression level of the RNF40 gene. We successfully isolated two T/T colonies and one C/T colony for functional testing (T is the MM risk associated allele). A 2.3-fold decrease in proliferation was observed in T/T colonies and 2.9 for colonies with C/T genotype compared to the C/C wild type (p=0.02). The migration assay showed a significant increase in cell migration of 3-fold (p=0.002) for the cells carrying the T allele. A significant increase of the expression of RNF40 was also observed when comparing the 3 genotypes in the cell lines, with the highest expression in T/T cells (p=0.001). A similar difference was observed in the BM patients as well, although not significant. **Conclusions:** We successfully edited the genotypes of interest and observed a decrease in proliferation and an increase in migration in colonies with the MM risk allele, as well as a significant increase in the expression of RNF40. These findings confirmed the functional role of rs3747481. However, further experiments will be needed to better understand the biological mechanism of action of the polymorphism.

A novel genomewide RNA-Targeting CRISPR/Cas13 screen identifies a plasma cell-specific long non-coding RNA (LncRNA) essential for myeloma cell growth

Domenico Maisano[1], Anil Aktas-Samur[1], Claire Gao[1], Na Liu[1], Vanessa Favasuli[1], Pietro Folino[1], Annamaria Gulla[2], Kenneth Anderson[3], Carl Novina[1], Mariateresa Fulciniti[1], Mehmet Samur[1], Eugenio Morelli[1], Nikhil Munshi[4]

[1]Dana-Farber Cancer Institute; [2]Candiolo Cancer Institute; [3]LeBow Institute for Myeloma Therapeutics and Jerome Lipper Center for Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts; [4]Dana-Farber Cancer Institute, Boston, MA, USA, Veterans Affairs Boston Healthcare System/Harvard Medical School

Introduction: Long non-coding RNAs (lncRNAs) are abundant RNA molecules that outnumber protein-coding genes in the human genome. They play significant roles in biological processes by interacting with proteins and other nucleic acids. Our previous work using RNA-seq data and a CRISPRi screen identified a series of lncRNAs as independent predictors of clinical outcome and confirmed their functional significance in promoting MM cell growth. However, CRISPRi focuses just on lncRNAs with defined transcription start sites. **Methods:** To find tumor-promoting lncRNAs in a genomewide unbiased manner, we have exploited the RNA-targeting activity of the CRISPR-Cas13d endonuclease, which enables the selective knockdown of lncRNA transcripts of any genomic origin. We have used it to perform viability screens in five MM cell lines, targeting > 6,000 lncRNAs whose expression was identified using RNA-seq data from CD138+ MM cells from 360 MM patients. We developed a pooled lentiviral library comprising 60,000 sgRNAs, with 9 of them per lncRNA and > 500 non-targeting sgRNAs as negative controls. This library was infected at a low MOI (< 0.3) into five MM cell lines (AMO1, H929, KMS11, OPM2, R8226) expressing Cas13d. After three weeks, we employed MAGeCK robust rank aggregation (RRA) algorithm to identify sgRNAs that displayed either depletion or enrichment within the MM cell population. **Results:** We identified 155 lncRNAs essential for MM cell proliferation. A novel lncRNA named MYND1, was one of the most abundant lncRNAs in MM and normal plasma cells (median TPM>25), whereas it is significantly lower or absent in 54 normal tissues and cell types. RT-qPCR confirmed the plasma-cell specificity of MYND1 and its higher expression in MM cells compared to plasma cells. Furthermore, using subcellular qRT-PCR, we detected MYND1 mostly in the nucleus. Higher MYND1 expression predicted a worse clinical outcome in the newly diagnosed MM patients (n=360) enrolled in the IFM/DFCI clinical trial 2009 (NCT01191060). Knocking down MYND1 using antisense oligonucleotides in three MM cell lines (AMO1, H929, and KMS11) caused significant time-dependent inhibition of MM cell viability. Following MYND1 depletion in AMO1 cells, RNA-seq and GSEA identified significant modulation of expression of splice variants and inhibition of spliceosome-related gene signatures. MYND1 shares half of its sequence with U1 small nuclear RNA, a key component of the spliceosome complex. We confirmed the extensive interaction of MYND1 with spliceosome components HNRNPC, HNRNPH2, and HNRNPH3 in MM cells using ChIRP-MS and in vitro using RPPD-MS. **Conclusions:** The functional impact of modulating MYND1 on spliceosome proteins is currently under investigation. Furthermore, ongoing nucleotide pairing analysis and structure simulations are being conducted to determine the optimal MYND1 targeting strategy. Our preliminary study suggests that MYND1 supports splicing activity, thus promoting MM cell growth and survival, and is a potential therapeutic target.

Effect of amplification or gain of 1Q21 in patients with multiple myeloma treated with daratumumab

Irene Zamanillo[1], Lucia Medina de Alba[1], Rafael Alonso[1], Jose Maria Sanchez[1], Clara Cuellar[1], Manuela Fernandez-Guijarro[2], Joaquín Martínez-López[1]

[1]University Hospital 12 de Octubre; [2]Hospital 12 de Octubre, Instituto de Investigación Hospital 12 de Octubre (i+12), Centro Nacional de Investigaciones Oncológicas (CNIO), Universidad Complutense

Introduction: Gain and amplification of 1q21 have been proposed as prognostic markers in patients with multiple myeloma, and there is evidence that these alterations may be associated with worse responses to anti-CD38 monoclonal antibodies (1, 2, 3). In this study, we analyzed the effect of 1q alterations on the prognosis of patients with multiple myeloma treated with isatuximab and daratumumab. **Methods:** We collected retrospective data from 117 patients treated with daratumumab at our center. Patients were considered eligible if they had cytogenetic studies and response evaluation. +1q alterations were classified as gain if 3 copies of the gene were found and amplification if 4 or more copies were present determined by FISH. **Results:** The median age at diagnosis was 66 years, and 54.7% were women. A total of 23.1% had high-risk ISS-R at diagnosis, and 16.2% had extramedullary involvement. Most of the cohort (80 patients, 68.4%) were relapsed or refractory to previous lines, and received daratumumab therapy after a median of 1 previous line (0-6). In the majority of the cases, daratumumab was administered in combination with other anti-myeloma agents, and only 14.5% of patients received it as monotherapy. A total of 26.5% of patients had 1q gain, and 24.7% had amplification. Overall, the progression-free survival (PFS) in the group of patients with 1q gain or amplification was 14 months compared to 28 months in those without any alteration in 1q, showing a hazard ratio (HR) for PFS of 1.75 (CI 1.05-2.88). Analyzing patients with gain and amplification separately, only patients with 1q amplification maintained a statistically significant difference in the risk of progression (12 vs 28 months; p=0.019; HR 1.9, CI 1.06-3.40), while patients with 1q gain showed a non-significant trend towards shorter PFS (19

origin. Ongoing studies will incorporate genetic admixture alongside somatic genomic assessment to accurately investigate progression risk from precursor disease to MM.

Effect of amplification or gain of 1Q21 in patients with multiple myeloma treated with daratumumab

Irene Zamanillo[1], Lucia Medina de Alba[1], Rafael Alonso[1], Jose Maria Sanchez[1], Clara Cuellar[1], Manuela Fernandez-Guijarro[2], Joaquín Martínez-López[1]

[1]University Hospital 12 de Octubre; [2]Hospital 12 de Octubre, Instituto de Investigación Hospital 12 de Octubre (i+12), Centro Nacional de Investigaciones Oncológicas (CNIO), Universidad Complutense

Introduction: Gain and amplification of 1q21 have been proposed as prognostic markers in patients with multiple myeloma, and there is evidence that these alterations may be associated with worse responses to anti-CD38 monoclonal antibodies (1, 2, 3). In this study, we analyzed the effect of 1q alterations on the prognosis of patients with multiple myeloma treated with isatuximab and daratumumab. **Methods:** We collected retrospective data from 117 patients treated with daratumumab at our center. Patients were considered eligible if they had cytogenetic studies and response evaluation. +1q alterations were classified as gain if 3 copies of the gene were found and amplification if 4 or more copies were present determined by FISH. **Results:** The median age at diagnosis was 66 years, and 54.7% were women. A total of 23.1% had high-risk ISS-R at diagnosis, and 16.2% had extramedullary involvement. Most of the cohort (80 patients, 68.4%) were relapsed or refractory to previous lines, and received daratumumab therapy after a median of 1 previous line (0-6). In the majority of the cases, daratumumab was administered in combination with other anti-myeloma agents, and only 14.5% of patients received it as monotherapy. A total of 26.5% of patients had 1q gain, and 24.7% had amplification. Overall, the progression-free survival (PFS) in the group of patients with 1q gain or amplification was 14 months compared to 28 months in those without any alteration in 1q, showing a hazard ratio (HR) for PFS of 1.75 (CI 1.05-2.88). Analyzing patients with gain and amplification separately, only patients with 1q amplification maintained a statistically significant difference in the risk of progression (12 vs 28 months; p=0.019; HR 1.9, CI 1.06-3.40), while patients with 1q gain showed a non-significant trend towards shorter PFS (19

vs 28 months; p=0.084; HR 1.6, CI 0.9-2.9). The influence of 1q alterations on progression remained significant in the multivariate analysis, including other cytogenetic abnormalities (del17p, t(4;14); t(14;16), del1p) (p=0.011). The differences in PFS, however, did not translate into a shorter overall survival (OS). **Conclusions:** The presence 1q amplification is a poor prognostic factor in patients with multiple myeloma treated with daratumumab and it was associated with shorter PFS in our cohort. Patients with 1q gain showed a trend towards shorter PFS, although it did not reach statistical significance. A larger sample size is needed to confirm this findings.

Introduction: Outcomes for newly diagnosed multiple myeloma (NDMM) patients are heterogenous, with overall survival (OS) ranging from months to over 10 years. Though genomic events strongly contribute to clinical outcomes, yet the "one-size-fits-all" treatment paradigm remains dominant for NDMM. **Methods:** To decipher the molecular and clinical heterogeneity at unprecedented depth and develop the first artificial intelligence individualized prediction model for risk in NDMM (IRMMa), we assembled a large training (n=1933) and validation (n=256) set of patients with NDMM with available clinical-, genomic-, and therapeutic data. The training set was composed by the following cohorts: MMRF CoMMpass (n=1062), Myeloma Genome Project (n=492), Moffit AVATAR (n=177), and MSKCC MyTYPE (n=109). The validation set included patients enrolled in the GMMG-HD6 (NCT02495922) clinical trial with available whole genome sequencing (WGS). **Results:** To integrate clinical, demographic, genomic, and treatment data we compared different methods of predicting OS and event-free survival (EFS). Overall the Neural Cox Non-proportional-hazards (NCNPH)-based model emerged as most accurate in predicting EFS and OS, (c-index 0.69 and 0.73, respectively) and was used as the core-engine of IRMMa. IRMMa's accuracy was significantly higher than all existing prognostic models: ISS (EFS: 0.56; OS: 0.61), R-ISS (EFS: 0.54, OS: 0.57), R2-ISS (EFS 0.56; OS: 0.63). Among all 132 genomic features tested, only twenty significantly improved model accuracy for OS, including deletions on 1p, 1q21 gain/amp, TP53 loss, t(4;14)(NSD2;IGH), a high contribution of the APOBEC mutational signature and copy number variation signatures indicating chromothripsis. Importantly, while the inclusion of each feature improved the model accuracy, IRMMa has been developed as a flexible tool able to predict outcomes with incomplete data. Specifically, because genomic profiling is only rarely performed in current clinical practice, IRMMa performance was tested without genomic data. Despite this, IRMMa still outperformed ISS, R-ISS, and R2-ISS with EFS and OS c-index of 0.69 and 0.71, respectively. IRMMa accuracy and superiority compared to other prognostic models were validated on 256 patients enrolled in the GMMG-HD6 (NCT02495922) clinical trial. As a key innovation, IRMMa is able to predict differences in outcomes across different treatment combinations and strategies. For instance, using IRMMa we were able to predict NDMM patients, in whom high-dose melphalan followed by autologous stem cell transplant (HDM-ASCT) provides a significant advantage, and those in whom HDM-ASCT does not impact outcome. **Conclusions:** Integrating clinical, demographic, genomic, and therapeutic data, we have developed the first individualized risk-prediction model enabling personally tailored therapeutic decisions for NDMM patients.

Introduction: Less than 5% of all multiple myeloma (MM) are diagnosed < 45 years. Previous studies have described the clinical characteristics and validated MM prognostic variables, but the molecular characteristics of this group are unclear. **Methods:** 129 patients with MM diagnosed at age ≤45 at a single center (Weill Cornell, WCM) were reviewed and compared to a randomly selected group of 101 patients ≥ 63 years. All patients met IMWG MM diagnosis and response criteria. Patients ≤ 45 years (55 patients) in the MM Research Foundation (MMRF) CoMMpass were compared to those ≥63 years (548 patients). The control group age >63 was

vs 28 months; p=0.084; HR 1.6, CI 0.9-2.9). The influence of 1q alterations on progression remained significant in the multivariate analysis, including other cytogenetic abnormalities (del17p, t(4;14); t(14;16), del1p) (p=0.011). The differences in PFS, however, did not translate into a shorter overall survival (OS). **Conclusions:** The presence 1q amplification is a poor prognostic factor in patients with multiple myeloma treated with daratumumab and it was associated with shorter PFS in our cohort. Patients with 1q gain showed a trend towards shorter PFS, although it did not reach statistical significance. A larger sample size is needed to confirm this findings.

Myeloma at a younger age presents with distinctive clinical and molecular features

Mateo Mejia Saldarriaga[1], Aubrie Sowa[2], Jorge Contreras[1], David Jayabalan[1], Cara Rosenbaum[1], Roger Pearse[1], Jorge Monge[3], Ruben Niesvizky[4], Mark Bustoros[1]

[1]Weill Cornell Medicine; [2]University College Dublin Medical Schoo; [3]Weill Cornell Medicine Myeloma Center; [4]Division of Oncology & Hematology, Weill Cornell Medicine, New York, NY, USA*

Introduction: Less than 5% of all multiple myeloma (MM) are diagnosed < 45 years. Previous studies have described the clinical characteristics and validated MM prognostic variables, but the molecular characteristics of this group are unclear. **Methods:** 129 patients with MM diagnosed at age ≤45 at a single center (Weill Cornell, WCM) were reviewed and compared to a randomly selected group of 101 patients ≥ 63 years. All patients met IMWG MM diagnosis and response criteria. Patients ≤ 45 years (55 patients) in the MM Research Foundation (MMRF) CoMMpass were compared to those ≥63 years (548 patients). The control group age >63 was

selected to identify those above the median age and diminish overlap between groups. **Results:** African American (AA) were enriched in the ≤ 45 year groups in both cohorts (WCM 31% vs 13%, MMRF 33% vs 15%, p 45 years at diagnosis (183 patients) as a control in the WCM cohort showed similar results. Lower incidence of deletion 13q and gain 1q in the ≤ 45 years cohort (35% vs 50% p = 0.03, and 22% vs 42% p < 0.01) when compared to the ≥ 63 year cohort was seen. There were no differences in the rate of recurrent translocation, deletion, or mutations in MM. Enrichment of the CD-1 (associated with Cyclin D1) subgroup in the ≤ 45 years subgroup, while the LB (low bone) and HP (associated with hyperdiploidy) were enriched in the older group. Mutational signature analysis was done including all single nucleotide variants, the ≥ 63 year had higher mutational burden (3.8 vs 3.3 mut/Mb, p < 0.01), due to higher count and frequency of clock-like signatures (COSMIC 1 and 5), while there were no differences in other signatures. **Conclusions:** Young MM represents a distinct clinical enriched for AA, lower ISS stage and likely higher functional class and physiologic reserve (higher ASCT and lower ECOG), leading to improved PFS/OS, likely derived from better tolerance to highly active therapies and less attrition after progression. We identified a distinct molecular subgroup enriched for CD-1 signature and lower rates of deletion 13q and gain 1q, with a higher mutational burden due to higher clock-like signatures which suggest a later time of disease onset. There were no differences in the rate of recurrent translocation, hyperdiploidy or mutations. Genomic studies focused in AAs/Hispanics germline and somatic factors associated with MM are required to identify the biological origin for the observed differences.

Non-paraskeletal extramedullary disease is associated with high rates of high risk cytogenetic alterations and has a distinct transcriptional profile

Mateo Mejia Saldarriaga[1], Caitlin Unkenholz[1], David Jayabalan[1], Jorge Contreras[1], Roger Pearse[1], Cara Rosenbaum[1], Jorge Monge[1], Ruben Niesvizky[1], Mark Bustoros[1]

[1]Weill Cornell Medicine

Introduction: Extramedullary disease (EMD) is seen in up to a third of patients during multiple myeloma (MM) courses, and it is associated with worse outcomes (overall survival (OS) and progression-free survival (PFS)) despite the upfront use of autologous stem cell transplant (ASCT), proteasome inhibitor, and immunomodulatory drugs combination. However, molecular drivers of EMD are poorly characterized. **Methods:** A 124-patient cohort with EMD (70 paraskeletal (PS) and 48 non-paraskeletal (non-PS)) from a single institution (Weill Cornell, WCM) were compared to a randomly selected non-EMD MM control group (232 patients). The MM Research Foundation (MMRF) CoMMpass registry was queried, and patients who developed non-PS EMD (184 patients) at any point were compared to non-EMD group (957 patients). Baseline characteristics and clinical outcomes were compared. Copy number alterations, structural variants, point mutations, differential expression analysis (DEA) and mutational signature were compared in the MMRF cohort from the sample at diagnosis. Analysis of Whole exome and RNA sequencing of 8 matched bone marrow-EMD biopsies is currently underway and will be available at the meeting. **Results:** EMD is associated with lower M protein (p = 0.02) and higher hemoglobin (p < 0.01) at diagnosis in the MMRF. Lower OS (WCM: HR 3.4, CI 1.5-7.9 p < 0.01, MMRF: HR 1.5, CI 1.2-1.9, p = 0.018) and PFS (MMRF: HR 1.51, 95CI (1.23 - 1.87), p < 0.01) were seen in non-PS EMD after adjusting for ASCT use, presence of anemia, LDH, ISS, and high-risk cytogenetics. The use of ASCT, maintenance, and triplet induction led to improved outcomes, but the effect of EMD was not abrogated. Landmark analysis was performed in the MMRF for ASCT and maintenance with similar results. Non-PS EMD was associated with higher rates of del17p (WCM 29% vs 14%, p 0.02), TP53 mutations (MMRF 9.6% vs 4.4%, p 0.02) and biallelic TP53 inactivation (MMRF 7.3% vs 2.9%, p 0.01), gain 1q (MMRF 44% vs 37%, WCM 47% vs 27%, p 0.01), del13q (WCM 53% vs 33%, p 0.02), Amp 8q24 (MYC, MMRF 27% vs 15%, p < 0.01) and del18q (MMRF 23% vs 14%, p < 0.01) when compared to non-EMD cases. There were no differences in mutations in top 25 recurrent genes. DEA and GSEA showed enrichment of the MYC target, E2F, G2M checkpoint pathways, and of the CD-1 (CCND1), CTA (cancer testis antigen), and PR (proliferative) myeloma subgroups, while there was lower expression of the focal adhesion molecules (FAC) pathway, MS, MF, and LB myeloma subgroups non-EMD samples. There were no differences in tumor mutation burden or selected COSMIC signature frequency between EMD and non-EMD samples. **Conclusions:** Non-PS EMD is associated with worse clinical outcomes, with higher incidence of known high-risk molecular alterations (del17p, gain1q), in addition to other not previously identified such as amp8q24 (MYC). This correlates with enrichment for MYC and lower expression of FAC pathways. Non-PS samples are enriched for CD-1, PR, and CTA, the latter two associated with aggressive disease.

Introduction: Multiple myeloma (MM) is the second most common hematologic malignancy and remains an incurable disease. There is a significant unmet need to identify and characterise biology associated with high-risk and therapy resistance. The Polycomb repressive complex 2 (PRC2) is a chromatin regulatory complex which acts as an epigenetic mediator to control gene transcription by its enzymatic activity to catalyse tri-methylation of histone 3 lysine 27 residues (H3K27me3). The expression of PRC2 members EZH2 and

selected to identify those above the median age and diminish overlap between groups. **Results:** African American (AA) were enriched in the ≤ 45 year groups in both cohorts (WCM 31% vs 13%, MMRF 33% vs 15%, p 45 years at diagnosis (183 patients) as a control in the WCM cohort showed similar results. Lower incidence of deletion 13q and gain 1q in the ≤ 45 years cohort (35% vs 50% p = 0.03, and 22% vs 42% p < 0.01) when compared to the ≥ 63 year cohort was seen. There were no differences in the rate of recurrent translocation, deletion, or mutations in MM. Enrichment of the CD-1 (associated with Cyclin D1) subgroup in the ≤ 45 years subgroup, while the LB (low bone) and HP (associated with hyperdiploidy) were enriched in the older group. Mutational signature analysis was done including all single nucleotide variants, the ≥ 63 year had higher mutational burden (3.8 vs 3.3 mut/Mb, p < 0.01), due to higher count and frequency of clock-like signatures (COSMIC 1 and 5), while there were no differences in other signatures. **Conclusions:** Young MM represents a distinct clinical enriched for AA, lower ISS stage and likely higher functional class and physiologic reserve (higher ASCT and lower ECOG), leading to improved PFS/OS, likely derived from better tolerance to highly active therapies and less attrition after progression. Introduction: Multiple myeloma (MM) is the second most common hematologic malignancy and remains an incurable disease. There is a significant unmet need to identify and characterise biology associated with high-risk and therapy resistance. The Polycomb repressive complex 2 (PRC2) is a chromatin regulatory complex which acts as an epigenetic mediator to control gene transcription by its enzymatic activity to catalyse tri-methylation of histone 3 lysine 27 residues (H3K27me3). The expression of PRC2 members EZH2 and

selected to identify those above the median age and diminish overlap between groups. **Results:** African American (AA) were enriched in the ≤ 45 year groups in both cohorts (WCM 31% vs 13%, MMRF 33% vs 15%, p 45 years at diagnosis (183 patients) as a control in the WCM cohort showed similar results. Lower incidence of deletion 13q and gain 1q in the ≤ 45 years cohort (35% vs 50% p = 0.03, and 22% vs 42% p < 0.01) when compared to the ≥ 63 year cohort was seen. There were no differences in the rate of recurrent translocation, deletion, or mutations in MM. Enrichment of the CD-1 (associated with Cyclin D1) subgroup in the ≤ 45 years subgroup, while the LB (low bone) and HP (associated with hyperdiploidy) were enriched in the older group. Mutational signature analysis was done including all single nucleotide variants, the ≥ 63 year had higher mutational burden (3.8 vs 3.3 mut/Mb, p < 0.01), due to higher count and frequency of clock-like signatures (COSMIC 1 and 5), while there were no differences in other signatures. **Conclusions:** Young MM represents a distinct clinical enriched for AA, lower ISS stage and likely higher functional class and physiologic reserve (higher ASCT and lower ECOG), leading to improved PFS/OS, likely derived from better tolerance to highly active therapies and less attrition after progression. We identified a distinct molecular subgroup enriched for CD-1 signature and lower rates of deletion 13q and gain 1q, with a higher mutational burden due to higher clock-like signatures which suggest a later time of disease onset. There were no differences in the rate of recurrent translocation, hyperdiploidy or mutations. Genomic studies focused in AAs/Hispanics germline and somatic factors associated with MM are required to identify the biological origin for the observed differences.

Non-paraskeletal extramedullary disease is associated with high rates of high risk cytogenetic alterations and has a distinct transcriptional profile

Mateo Mejia Saldarriaga[1], Caitlin Unkenholz[1], David Jayabalan[1], Jorge Contreras[1], Roger Pearse[1], Cara Rosenbaum[1], Jorge Monge[1], Ruben Niesvizky[1], Mark Bustoros[1]

[1]Weill Cornell Medicine

Introduction: Extramedullary disease (EMD) is seen in up to a third of patients during multiple myeloma (MM) courses, and it is associated with worse outcomes (overall survival (OS) and progression-free survival (PFS)) despite the upfront use of autologous stem cell transplant (ASCT), proteasome inhibitor, and immunomodulatory drugs combination. However, molecular drivers of EMD are poorly characterized. **Methods:** A 124-patient cohort with EMD (70 paraskeletal (PS) and 48 non-paraskeletal (non-PS)) from a single institution (Weill Cornell, WCM) were compared to a randomly selected non-EMD MM control group (232 patients). The MM Research Foundation (MMRF) CoMMpass registry was queried, and patients who developed non-PS EMD (184 patients) at any point were compared to non-EMD group (957 patients). Baseline characteristics and clinical outcomes were compared. Copy number alterations, structural variants, point mutations, differential expression analysis (DEA) and mutational signature were compared in the MMRF cohort from the sample at diagnosis. Analysis of Whole exome and RNA sequencing of 8 matched bone marrow-EMD biopsies is currently underway and will be available at the meeting. **Results:** EMD is associated with lower M protein (p = 0.02) and higher hemoglobin (p < 0.01) at diagnosis in the MMRF. Lower OS (WCM: HR 3.4, CI 1.5-7.9 p < 0.01, MMRF: HR 1.5, CI 1.2-1.9, p = 0.018) and PFS (MMRF: HR 1.51, 95CI (1.23 - 1.87), p < 0.01) were seen in non-PS EMD after adjusting for ASCT use, presence of anemia, LDH, ISS, and high-risk cytogenetics. The use of ASCT, maintenance, and triplet induction led to improved outcomes, but the effect of EMD was not abrogated. Landmark analysis was performed in the MMRF for ASCT and maintenance with similar results. Non-PS EMD was associated with higher rates of del17p (WCM 29% vs 14%, p 0.02), TP53 mutations (MMRF 9.6% vs 4.4%, p 0.02) and biallelic TP53 inactivation (MMRF 7.3% vs 2.9%, p 0.01), gain 1q (MMRF 44% vs 37%, WCM 47% vs 27%, p 0.01), del13q (WCM 53% vs 33%, p 0.02), Amp 8q24 (MYC, MMRF 27% vs 15%, p < 0.01) and del18q (MMRF 23% vs 14%, p < 0.01) when compared to non-EMD cases. There were no differences in mutations in top 25 recurrent genes. DEA and GSEA showed enrichment of the MYC target, E2F, G2M checkpoint pathways, and of the CD-1 (CCND1), CTA (cancer testis antigen), and PR (proliferative) myeloma subgroups, while there was lower expression of the focal adhesion molecules (FAC) pathway, MS, MF, and LB myeloma subgroups non-EMD samples. There were no differences in tumor mutation burden or selected COSMIC signature frequency between EMD and non-EMD samples. **Conclusions:** Non-PS EMD is associated with worse clinical outcomes, with higher incidence of known high-risk molecular alterations (del17p, gain1q), in addition to other not previously identified such as amp8q24 (MYC). This correlates with enrichment for MYC and lower expression of FAC pathways. Non-PS samples are enriched for CD-1, PR, and CTA, the latter two associated with aggressive disease.

Introduction: Multiple myeloma (MM) is the second most common hematologic malignancy and remains an incurable disease. There is a significant unmet need to identify and characterise biology associated with high-risk and therapy resistance. The Polycomb repressive complex 2 (PRC2) is a chromatin regulatory complex which acts as an epigenetic mediator to control gene transcription by its enzymatic activity to catalyse tri-methylation of histone 3 lysine 27 residues (H3K27me3). The expression of PRC2 members EZH2 and

cofactors PHF19 have been associated with inferior overall survival in MM patients. Following this observation, using data from over 1500 MM patients, we investigated the genomic and transcriptomic landscape of the PRC2 complex in high-risk MM patients with a view to identify novel therapeutic targets. We utilized the EZH2 inhibitor Tazemetostat (Taz) to identify MM cell lines sensitive and resistant to PRC2 inhibition. Furthermore, we map key transcriptomic differences in the sensitive lines. Through both chemical and genetic disruption, we investigate phenotypic differences in PRC2 activity in MM cell lines with different genetic backgrounds. **Methods:** The Myeloma Genome Project data was used to map the expression of PRC2 genes in MM patients. A panel of MM cell lines were treated with Taz to determine cells with sensitivity to inhibition of EZH2 methyltransferase. For subsequent experiments, cells were treated with either 1μM Taz or DMSO control for 5 days. RNAseq was performed to identify a gene signature associated with sensitivity to EZH2 inhibition and significant pathways associated with EZH2 inhibition in sensitive and resistant cell lines were identified. Using the MMRF patient dataset, a gene set variance analysis was used to assign a PRC2 associated activity score for each patient. ChIP-seq was performed and histone marks (H3K27ac, H3K27me3 and H3K4me3) were analyzed in differentially express genes. Gene expression in interferon response genes across a panel of MM lines was validated by qPCR. The expression of PRC2 components were modulated in MM cell lines by CRISPR-Cas9. Taz sensitivity and phenotypic differences in apoptosis and cell growth were measured. **Results:** Patients with a PRC2 dependant gene signature were identified by mapping genomic and transcriptomic activity of PRC2 and its interactions across MM patients. In addition, MM cell lines showed varying levels of sensitivity to Taz treatment. RNAseq experiments revealed several pathways significantly altered upon EZH2 inhibition in sensitive cell lines including upregulation of IFN response genes and MYC downregulation. Furthermore, upregulation of H3K27ac and H3K4me3, active histone marks, were identified in promoters of IFN response genes in Taz sensitive cells. These significant transcriptional changes of IFN expression were confirmed across a panel of MM cell lines. **Conclusions:** PRC2 plays a role in IFN-related gene expression and may constitute a therapeutic mechanism in high-risk MM patients.

Introduction: APOBEC mutational signatures are among the most important mutational signatures present in the majority of patients with newly diagnosed multiple myeloma (NDMM). APOBEC mutational signatures are primarily caused by two enzymes, APOBEC3A (A3A) and APOBEC3B (A3B). While these genes are expressed in most myeloma cells, their influence on APOBEC mutagenesis appear to be extremely heterogeneous, with some patients having no detectable mutations and others having high contribution (hyper-APOBEC). **Methods:** To decipher the mechanism of APOBEC mutagenesis, we utilized 752 whole genomes from NDMM patients enrolled in the CoMMpass study. 723 and 767 had available whole exome sequencing (WES) and RNA sequencing (RNA-Seq) data, respectively. **Results:** APOBEC activity was identified in 416/723 (57.5%) patients using WES. Of these, 41 (5.8%) had MAF/MAFB translocations. Overall, 48/723 (6.6%) patients were defined as hyper-APOBEC (13 without MAF/MAFB events). We used differential expression (DE) analysis between three groups: hyper-APOBEC with MAF/MAFB (HA_TRA: n=31), hyper-APOBEC without MAF/MAFB (HA_NORM: n=8), and non-hyper-APOBEC without MAF/MAFB (WT: n=510). We identified 534 APOBEC-associated genes which were independent from the MAF/MAFB events. Importantly, A3B was higher in hyper-APOBEC with and without MAF/MAFB, while A3A was mostly expressed in MAF/MAFB samples. Using Spearman's correlation, we identified 50 significantly correlated genes (rho-squared>0.18; $p< 0.00001$) with A3B. Most of the genes belonged to the APOBEC-associated group defined by the DE and showed cell cycle/proliferation activity, suggesting a link between highly proliferative disease and hyper-APOBEC. To validate this finding, we evaluated the link between these genes and hyper-APOBEC among ICGC breast cancers. Overall, 35 of these genes showed similar correlation in hyper-APOBEC breast. Interestingly, most of these genes appear to be negatively controlled by E2F4, and positively controlled by FOXM1 and MYBL2. These three transcription factors are well-established regulators of the DREAM complex, which has been shown to play a key role in APOBEC transcriptional regulation (Roelofs et al., eLife, 2020). Next, we compared 131 genomic events to identify potential differences between the hyper-APOBEC and WT. HA_TRA and HA_NORM showed similarities, including a highly complex genomic profile enriched for 1q gain, 13q and 16q deletions ($p< 0.05$). In terms of gene expression, both groups showed enrichment for GEP70 positivity. Finally, HA_TRA and HA_NORM showed similar poor outcomes compared to WT. **Conclusions:** Patients with hyper-APOBEC NDMM are characterized by a distinct transcriptional profile with high cell proliferation, reduced inhibition by the DREAM complex, and a high level of genomic complexity reflected in poorer clinical outcomes.

Introduction: Multiple myeloma (MM) is often sustained by chromosomal translocations that involve super-enhancers and transcription factors (TF), thus leading to a profound rewiring of transcriptional circuits. This generates MM specific non-oncogene addictions on TFs, including a strong dependency on the poorly characterized basic helix-loop-helix transcription factor (bHLH) TCF3 (E2A). Here we identify and describe Inhibitor of DNA binding 2 (ID2) as a potent tumor suppressor in MM thanks to its ability to prevent TCF3 activity. **Methods:** We combined genome-wide unpublished CRISPRa and CRISPRi screen and RNA-seq of MM patients to identify deregulation of ID2-TCF3 axis in MM. We manipulated ID2 and TCF3 expression by inducible lentiviral platforms and performed both unbiased (RNA-seq, proteomics, ATAC-seq) and hypothesis driven (analysis of cell cycle, proliferation, EMSA assays) experiments to test its role in MM cell. **Results:** We performed a genome-wide CRISPRa screen in three MM cell lines (AMO1, ANBL6 and JJN3), and identified the Inhibitor of DNA binding (ID) genes among the top hits inhibiting MM cell fitness. Importantly, the ID proteins (ID1, ID2, ID3, and ID4) can inhibit bHLH transcription factors, in particular E proteins like TCF3, by preventing their binding to DNA. We have therefore evaluated their expression in MM patients and found that ID2 is specifically and significantly downregulated in malignant plasma vs. normal plasma cells ($p = 0.0059$). Moreover, data from a genome-wide CRISPRi screen in 16 MM cell lines showed that only ID2 KO confers a proliferative advantage in a subset of MM cell lines (CSS score ≥ 0.5), mainly those with naturally higher ID2 expression. Mechanistically, by co-immunoprecipitation and mass-spectrometry we found that ID2 preferentially binds to TCF3 in MM cells, and we used an EMSA assay to find that ID2 overexpression caused a loss of TCF3 DNA-binding activity. This led to transcriptomic changes that caused cell-cycle arrest in G1 and subsequent senescence, with a complete halt in proliferation in three MM cell lines. Importantly, this anti-myeloma effect was partially rescued by TCF3 overexpression. In summary, we hypothesize that the lower ID2 expression observed in MM cells confers a proliferative advantage by allowing higher TCF3 activity, supporting growth and proliferation. Finally, we demonstrated that soluble factors secreted by bone marrow stromal cells induce further downregulation of ID2 expression at the transcriptional and protein levels, together with an increase in TCF3 binding motifs availability in open chromatin regions. Also in this context, overexpression of ID2 reduces TCF3 binding activity and prevents MM proliferation. **Conclusions:** In conclusion, we identified a novel tumor suppressor role for ID2 in MM and propose a model where MM cells unleash the whole oncogenic/proliferative potential of TCF3 by deregulating its inhibitor with the support of the bone marrow milieu.

Mitochondrial protease ClpP is a novel immunogenic vulnerability in multiple myeloma

Tommaso Perini[1], Paola Zordan[2], Rossella Del Pizzo[1], Laura Oliva[1], Maria Materozzi[1], Mehmet Samur[3], Ugo Orfanelli[1], Enrico Milan[2], Nikhil Munshi[4], Bellone Matteo[2], Simone Cenci[1]

[1]IRCCS Ospedale San Raffaele; [2]Vita-Salute San Raffaele University; [3]Dana-Farber Cancer Institute; [4]Dana-Farber Cancer Institute, Boston, MA, USA, Veterans Affairs Boston Healthcare System/Harvard Medical School

Introduction: Mitochondria orchestrate key homeostatic functions in cancer cells. Moreover, due to their bacterial origin, they can release potent immunogenic signals in the cytosol. ClpP, a resident protease of the mitochondrial matrix, has been proposed as a target in OXPHOS-dependent cancer cells, and its ablation is associated with mitochondrial DNA (mtDNA) leakage-driven cGAS-STING activation in fibroblasts. Prompted by the distinctive expression of ClpP in malignant plasma cells (PC) and by the value of activating STING to awaken immunity, we here evaluated ClpP as a possible target with both cell-intrinsic and immunostimulatory effects against multiple myeloma (MM). **Methods:** We manipulated ClpP expression in MM cell lines, by both stable and inducible shRNA-mediated knockdown (KD), and assessed tumor growth in vitro and in vivo. We evaluated the effects of ClpP KD by Seahorse bioenergetic profiling, transcriptomics, proteomics, metabolomics and metabolite tracing experiments. Activation of cGAS-STING and downstream effects on immune cells were evaluated in coculture experiments of MM, dendritic and T cells. **Results:** ClpP mRNA was significantly higher in bone marrow-purified malignant vs. normal PCs, and MM cell lines showed exquisite sensitivity to both acute and inducible KD of ClpP in vitro. Importantly, inducible silencing of ClpP in MM cells delayed tumor growth and prolonged survival in immunodeficient mice. Toxicity proved independent of the currently acknowledged ClpP-controlled mitochondrial functions (mainly OXPHOS surveillance and maintenance of ATP production). Indeed, an integrated proteomic and metabolomic approach revealed derangement in citric acid and urea cycles, together with depletion of the polyamines spermidine, spermine and putrescine upon ClpP KD. Concordantly, inhibition of spermidine biosynthesis or of its usage phenocopied ClpP KD toxicity MM cells. In parallel, unbiased proteomics and RNA-seq, followed by targeted biochemical validation, identified transcriptional upregulation of IFN-stimulated genes and activation of cGAS-STING upon ClpP KD. In line with a downstream secretion of type-I IFNs and proinflammatory molecules, ClpP KD MM cell supernatants significantly boosted maturation and activation of human dendritic cells and enhanced their ability to stimulate IFN-Γ production by CD8+ T cells. **Conclusions:** Overall, our data demonstrate that ClpP is essential to MM cells due to a novel non-bioenergetic function, with both intra- and extra-cellular implications. ClpP manipulation

Introduction: Multiple myeloma (MM) is often sustained by chromosomal translocations that involve super-enhancers and transcription factors (TF), thus leading to a profound rewiring of transcriptional circuits. This generates MM specific non-oncogene addictions on TFs, including a strong dependency on the poorly characterized basic helix-loop-helix transcription factor (bHLH) TCF3 (E2A). Here we identify and describe Inhibitor of DNA binding 2 (ID2) as a potent tumor suppressor in MM thanks to its ability to prevent TCF3 activity. **Methods:** We combined genome-wide unpublished CRISPRa and CRISPRi screen and RNA-seq of MM patients to identify deregulation of ID2-TCF3 axis in MM. We manipulated ID2 and TCF3 expression by inducible lentiviral platforms and performed both unbiased (RNA-seq, proteomics, ATAC-seq) and hypothesis driven (analysis of cell cycle, proliferation, EMSA assays) experiments to test its role in MM cell. **Results:** We performed a genome-wide CRISPRa screen in three MM cell lines (AMO1, ANBL6 and JJN3), and identified the Inhibitor of DNA binding (ID) genes among the top hits inhibiting MM cell fitness. Importantly, the ID proteins (ID1, ID2, ID3, and ID4) can inhibit bHLH transcription factors, in particular E proteins like TCF3, by preventing their binding to DNA. We have therefore evaluated their expression in MM patients and found that ID2 is specifically and significantly downregulated in malignant plasma vs. normal plasma cells ($p = 0.0059$). Moreover, data from a genome-wide CRISPRi screen in 16 MM cell lines showed that only ID2 KO confers a proliferative advantage in a subset of MM cell lines (CSS score ≥ 0.5), mainly those with naturally higher ID2 expression. Mechanistically, by co-immunoprecipitation and mass-spectrometry we found that ID2 preferentially binds to TCF3 in MM cells, and we used an EMSA assay to find that ID2 overexpression caused a loss of TCF3 DNA-binding activity. This led to transcriptomic changes that caused cell-cycle arrest in G1 and subsequent senescence, with a complete halt in proliferation in three MM cell lines. Importantly, this anti-myeloma effect was partially rescued by TCF3 overexpression. In summary, we hypothesize that the lower ID2 expression observed in MM cells confers a proliferative advantage by allowing higher TCF3 activity, supporting growth and proliferation. Finally, we demonstrated that soluble factors secreted by bone marrow stromal cells induce further downregulation of ID2 expression at the transcriptional and protein levels, together with an increase in TCF3 binding motifs availability in open chromatin regions. Also in this context, overexpression of ID2 reduces TCF3 binding activity and prevents MM proliferation. **Conclusions:** In conclusion, we identified a novel tumor suppressor role for ID2 in MM and propose a model where MM cells unleash the whole oncogenic/proliferative potential of TCF3 by deregulating its inhibitor with the support of the bone marrow milieu.

Mitochondrial protease ClpP is a novel immunogenic vulnerability in multiple myeloma

Tommaso Perini[1], Paola Zordan[2], Rossella Del Pizzo[1], Laura Oliva[1], Maria Materozzi[1], Mehmet Samur[3], Ugo Orfanelli[1], Enrico Milan[2], Nikhil Munshi[4], Bellone Matteo[2], Simone Cenci[1]

Introduction: Mitochondria orchestrate key homeostatic functions in cancer cells. Moreover, due to their bacterial origin, they can release potent immunogenic signals in the cytosol. ClpP, a resident protease of the mitochondrial matrix, has been proposed as a target in OXPHOS-dependent cancer cells, and its ablation is associated with mitochondrial DNA (mtDNA) leakage-driven cGAS-STING activation in fibroblasts. Prompted by the distinctive expression of ClpP in malignant plasma cells (PC) and by the value of activating STING to awaken immunity, we here evaluated ClpP as a possible target with both cell-intrinsic and immunostimulatory effects against multiple myeloma (MM). **Methods:** We manipulated ClpP expression in MM cell lines, by both stable and inducible shRNA-mediated knockdown (KD), and assessed tumor growth in vitro and in vivo. We evaluated the effects of ClpP KD by Seahorse bioenergetic profiling, transcriptomics, proteomics, metabolomics and metabolite tracing experiments. Activation of cGAS-STING and downstream effects on immune cells were evaluated in coculture experiments of MM, dendritic and T cells. **Results:** ClpP mRNA was significantly higher in bone marrow-purified malignant vs. normal PCs, and MM cell lines showed exquisite sensitivity to both acute and inducible KD of ClpP in vitro. Importantly, inducible silencing of ClpP in MM cells delayed tumor growth and prolonged survival in immunodeficient mice. Toxicity proved independent of the currently acknowledged ClpP-controlled mitochondrial functions (mainly OXPHOS surveillance and maintenance of ATP production). Indeed, an integrated proteomic and metabolomic approach revealed derangement in citric acid and urea cycles, together with depletion of the polyamines spermidine, spermine and putrescine upon ClpP KD. Concordantly, inhibition of spermidine biosynthesis or of its usage phenocopied ClpP KD toxicity MM cells. In parallel, unbiased proteomics and RNA-seq, followed by targeted biochemical validation, identified transcriptional upregulation of IFN-stimulated genes and activation of cGAS-STING upon ClpP KD. In line with a downstream secretion of type-I IFNs and proinflammatory molecules, ClpP KD MM cell supernatants significantly boosted maturation and activation of human dendritic cells and enhanced their ability to stimulate IFN-Γ production by CD8+ T cells. **Conclusions:** Overall, our data demonstrate that ClpP is essential to MM cells due to a novel non-bioenergetic function, with both intra- and extra-cellular implications. ClpP manipulation

unveils an unprecedented role of mitochondrial homeostasis in regulating polyamine biosynthesis and an unexplored dependency of MM on polyamines for survival and proliferation. Furthermore, ClpP ablation activates cGAS-STING in MM cells, paving the way for the exploration of mitochondria as targets to stimulate otherwise indolent anti-tumoral immunity against myeloma.

Novel FKBP12 targeting PROTACs enhances BMP-induced apoptosis in multiple myeloma

Ingrid Quist-Løkken[1], Michael Walz[2], Felix Hausch[2], Toril Holien[1]

[1]Norwegian University of Science and Technology; [2]Technische Universität Darmstadt

Introduction: Multiple myeloma is an incurable disease, which grows resistant to all known therapies. Previously it has been shown that targeting FKBP12 with FK506, also known as Tacrolimus, leads to apoptosis in multiple myeloma cells when FK506 is combined with bone morphogenetic proteins (BMPs). To avoid the immunosuppressive effects of FK506 we wanted to find methods of targeting FKBP12 that are non-immunosuppressive. PROteolysis TArgeting Chimeras (PROTACs) are compounds that specifically degrade proteins of interest and have emerged as a potential therapeutic strategy for cancer. There are a few FKBP12 targeting PROTACs commercially available, one of which has been shown to successfully remove FKBP12 in mice liver cells in vivo. Here, we investigated the efficacy of two novel FKBP12 PROTACs on BMP-induced signaling and apoptosis in multiple myeloma. **Methods:** We compared the effect of two novel FKBP12 specific PROTACs (unpublished) with the commercially available RC32 on BMP activity and apoptosis in multiple myeloma cells. FK506 and FKBP12 knock out cells were used as controls. Specifically, multiple myeloma cell lines were treated with PROTACs combined with BMP4 or BMP6 before analysis of FKBP12 and phospho-SMAD1/5/8 protein levels using western blot. Cell viability dose-response curves were made using CellTiter Glo and we used annexin V/propidium staining to show induction of apoptosis. SMAD1/5/8 activity was also investigated using a reporter cell line, INA-6 BRE-luc. To assess potential immunosuppressive effects, we measured the nuclear translocation of NFAT transcription factors by western blot. **Results:** We show that FKBP12 specific PROTACs potently reduced the protein level of FKBP12 without affecting other relevant FKBPs. The reduction in FKBP12 protein level correlated with increased BMP-induced SMAD1/5/8 phosphorylation. The use of FKBP12 specific PROTACs in multiple myeloma cell lines strongly potentiated BMP-induced apoptosis. The effect on apoptosis was similar to what we saw with the drug FK506 and when we knocked out FKBP12 from multiple myeloma cell lines. Out of these three ways of targeting FKBP12, only FK506 is immunosuppressive as measured by inhibition of NFAT nuclear translocation. **Conclusions:** We here show two novel PROTACs that potently reduce FKBP12 protein levels in multiple myeloma cells. The degradation of FKBP12 potentiates apoptosis in multiple myeloma cell lines when combined with BMPs. Further research is needed to verify efficacy and safety in vivo, but our in vitro results indicate a potential of FKBP12 specific PROTACs in multiple myeloma and supports further investigation.

Introduction: Multiple myeloma (MM) is a genetically complex disease characterized by driver events at diagnosis and precursor stages. Disease progression involves a complex interplay of genetic, epigenetic, and biochemical mechanisms, especially in extensively treated patients. We and others have recently shown that relapsed/refractory MM (RRMM) is characterized by impaired DNA damage response (DDR) and increased genomic instability resulting in drug resistance. To address this challenge, we aimed at exploring the therapeutic vulnerabilities conferred by these mechanistic hallmarks of RRMM using a high-throughput combinatorial drug screening approach in correlation with genetic markers. Additionally, we aimed to explore any potential associations between DDR deregulation and aberrations in the MAPK pathway, considering its known prevalence in drug-refractory MM. **Methods:** Human Myeloma Cell Lines (HMCLs) were used as a disease model. A panel of 26 HMCLs underwent panel Next Generation Sequencing (NGS) to characterize genomic alterations in the MAPK pathway and DDR genes. The high-throughput drug screening was conducted to investigate the single drug response of 29 drugs and 54 drug combinations. The data obtained from the drug screening were analysed using Bayesian Synergy, Synergy finder, and Drug Sensitivity Score (DSS) R packages. **Results:** The molecular characterization of the 26 HMCLs revealed a total of 242 genetic alterations. Mutations in tp53 (71%), KMT2C (42%), CDKN2C (38%), and RAS family proteins (38%) were commonly observed in our study. Three distinct groups were identified based on tumour mutational burden (TMB) scores. Sensitivity to Trametinib (MEK1/2 inhibitor) and SCH772984 (ERK inhibitor) were significantly associated with higher TMB values ($p < 0.05$). Ruxolitinib demonstrated higher effectiveness

unveils an unprecedented role of mitochondrial homeostasis in regulating polyamine biosynthesis and an unexplored dependency of MM on polyamines for survival and proliferation. Furthermore, ClpP ablation activates cGAS-STING in MM cells, paving the way for the exploration of mitochondria as targets to stimulate otherwise indolent anti-tumoral immunity against myeloma.

Introduction: Multiple myeloma (MM) is a genetically complex disease characterized by driver events at diagnosis and precursor stages. Disease progression involves a complex interplay of genetic, epigenetic, and biochemical mechanisms, especially in extensively treated patients. We and others have recently shown that relapsed/refractory MM (RRMM) is characterized by impaired DNA damage response (DDR) and increased genomic instability resulting in drug resistance. To address this challenge, we aimed at exploring the therapeutic vulnerabilities conferred by these mechanistic hallmarks of RRMM using a high-throughput combinatorial drug screening approach in correlation with genetic markers. Additionally, we aimed to explore any potential associations between DDR deregulation and aberrations in the MAPK pathway, considering its known prevalence in drug-refractory MM. **Methods:** Human Myeloma Cell Lines (HMCLs) were used as a disease model. A panel of 26 HMCLs underwent panel Next Generation Sequencing (NGS) to characterize genomic alterations in the MAPK pathway and DDR genes. The high-throughput drug screening was conducted to investigate the single drug response of 29 drugs and 54 drug combinations. The data obtained from the drug screening were analysed using Bayesian Synergy, Synergy finder, and Drug Sensitivity Score (DSS) R packages. **Results:** The molecular characterization of the 26 HMCLs revealed a total of 242 genetic alterations. Mutations in tp53 (71%), KMT2C (42%), CDKN2C (38%), and RAS family proteins (38%) were commonly observed in our study. Three distinct groups were identified based on tumour mutational burden (TMB) scores. Sensitivity to Trametinib (MEK1/2 inhibitor) and SCH772984 (ERK inhibitor) were significantly associated with higher TMB values ($p < 0.05$). Ruxolitinib demonstrated higher effectiveness

in IL-6 dependent myeloma cell lines ($p < 0.003$). Presence of DDR protein (tp53, ATR, ATM) mutations were associated with higher Drug Sensitivity scores in Nutlin-3a, UMI77, and Doxorubicin ($p< 0.05$). Among the drug combinations evaluated, BTK or PI3K inhibitors combined with PARP inhibitors, as well as DNA damage checkpoint inhibitors with ATM/ATR inhibitors exhibited the highest bayesynergy and Bliss scores for synergistic efficacy. Interestingly, combined BTK/PARP inhibition showed best efficacy in IKZF mutant cell lines, indicating a potential role in IMID-refractory disease. **Conclusions:** Our study underscores the significance of establishing ex vivo drug response panels in addition to NGS and immunochemistry data to advance precision medicine approaches in multiple myeloma. Addressing potential vulnerabilities created by common mechanisms of resistance may be more widely applicable than targeting rare activating mutations in RRMM. Therefore, by leveraging targeted therapy, patients can achieve favourable treatment responses, thus enabling them to gain access to subsequent immunotherapy options and maximize their therapeutic benefits.

Introduction: With the emergence of new therapeutic options, it is crucial to gain a comprehensive understanding of the toxicity profile associated with anti-multiple myeloma (MM) drug regimens (AMDRs). Previous studies have indicated that the occurrence of adverse events (AEs) may be influenced by specific genes and genetic factors. This study aims to investigate the link between genes, drug regimens, and AEs in AMDRs. By exploring the genetic evidence of neuro and renal AEs associated with specific regimens, we aim to understand the interplay between genetics and treatment-related toxicity in MM patients. **Methods:** The study used the 1DATA databank to integrate spontaneous reports (401,576 patients) of Human Drug AEs from openFDA, MedDRA, and ATC classification. An empirical Bayes approach converted RR values and variability to empirical Bayes geometric mean (EBGM). The 5th EBGM percentile (EB05) served as the lower bound for confidence intervals. Gene targets from AMDRs were obtained from DGIdb and DisGeNET. A comprehensive MM pharmacovigilance (PV) pharmacogenetics (PG) network was created using STRING and Gephi. The network depicted connections among drugs, genes, and MM through protein interactions. Gene expression data from MM patients and cells were obtained from MMRF CoMMpass and NCI's GDC using QIAGEN Ingenuity Pathway Analysis (QIAGEN IPA). **Results:** The first comparison was associated with the MM cell dataset for patients treated with K vs the control group, and three other MMRF datasets (KRd vs Rd, VRd vs Rd, and KRd vs VRd). We observed peripheral neuropathy was reported in VRd (EBGM = 3.47, EB05 = 3.11) and V (EBGM = 1.47, EB05 = 1.26) with EB05>1 in both regimens. We also found that NF-κB signaling pathway related to peripheral neuropathy was downregulated in MMRF (VRd vs Rd). Next, signaling pathways related to the renal (renal cell carcinoma signaling) and nervous (NF-κB signaling pathway related to peripheral neuropathy) systems were selected from the canonical pathways of four data comparisons (K vs control group, KRd vs Rd, VRd vs Rd, and KRd vs VRd) and we analyzed genes that were significantly altered. PV and PG analytics related to these systems associated with renal, nervous, and respiratory AEs were presented below. **Conclusions:** Doublet and triplet therapies like Rd, VRD, and KRd exhibited higher toxicity than V and K in PV. Dexamethasone-containing combinations showed worsened AE profiles. This novel methodology revealing nephro- and neuro-toxicity associations with specific AMDRs can potentially mitigate AEs and improve treatment tolerability.

Table 1 Drug EBGM>1 (EB05>1)

	Renal		Respiratory		Nervous	
	PV	PG	PV	PG	PV	PG
KRd	5 (2)	5 (2)	7 (4)	3 (3)	13 (2)	6 (1)
K	5 (2)	–	7 (2)	–	13 (1)	3
VRd	4 (1)	3 (1)	7	4	11 (3)	6 (2)
V	3	–	6	2	12 (1)	1
Rd	7 (2)	5 (2)	7 (2)	3 (1)	14 (3)	7 (3)
