in IL-6 dependent myeloma cell lines ($p < 0.003$). Presence of DDR protein (tp53, ATR, ATM) mutations were associated with higher Drug Sensitivity scores in Nutlin-3a, UMI77, and Doxorubicin ($p< 0.05$). Among the drug combinations evaluated, BTK or PI3K inhibitors combined with PARP inhibitors, as well as DNA damage checkpoint inhibitors with ATM/ATR inhibitors exhibited the highest bayesynergy and Bliss scores for synergistic efficacy. Interestingly, combined BTK/PARP inhibition showed best efficacy in IKZF mutant cell lines, indicating a potential role in IMID-refractory disease. **Conclusions:** Our study underscores the significance of establishing ex vivo drug response panels in addition to NGS and immunochemistry data to advance precision medicine approaches in multiple myeloma. Addressing potential vulnerabilities created by common mechanisms of resistance may be more widely applicable than targeting rare activating mutations in RRMM. Therefore, by leveraging targeted therapy, patients can achieve favourable treatment responses, thus enabling them to gain access to subsequent immunotherapy options and maximize their therapeutic benefits.

Introduction: With the emergence of new therapeutic options, it is crucial to gain a comprehensive understanding of the toxicity profile associated with anti-multiple myeloma (MM) drug regimens (AMDRs). Previous studies have indicated that the occurrence of adverse events (AEs) may be influenced by specific genes and genetic factors. This study aims to investigate the link between genes, drug regimens, and AEs in AMDRs. By exploring the genetic evidence of neuro and renal AEs associated with specific regimens, we aim to understand the interplay between genetics and treatment-related toxicity in MM patients. **Methods:** The study used the 1DATA databank to integrate spontaneous reports (401,576 patients) of Human Drug AEs from openFDA, MedDRA, and ATC classification. An empirical Bayes approach converted RR values and variability to empirical Bayes geometric mean (EBGM). The 5th EBGM percentile (EB05) served as the lower bound for confidence intervals. Gene targets from AMDRs were obtained from DGIdb and DisGeNET. A comprehensive MM pharmacovigilance (PV) pharmacogenetics (PG) network was created using STRING and Gephi. The network depicted connections among drugs, genes, and MM through protein interactions. Gene expression data from MM patients and cells were obtained from MMRF CoMMpass and NCI's GDC using QIAGEN Ingenuity Pathway Analysis (QIAGEN IPA). **Results:** The first comparison was associated with the MM cell dataset for patients treated with K vs the control group, and three other MMRF datasets (KRd vs Rd, VRd vs Rd, and KRd vs VRd). We observed peripheral neuropathy was reported in VRd (EBGM = 3.47, EB05 = 3.11) and V (EBGM = 1.47, EB05 = 1.26) with EB05>1 in both regimens. We also found that NF-κB signaling pathway related to peripheral neuropathy was downregulated in MMRF (VRd vs Rd). Next, signaling pathways related to the renal (renal cell carcinoma signaling) and nervous (NF-κB signaling pathway related to peripheral neuropathy) systems were selected from the canonical pathways of four data comparisons (K vs control group, KRd vs Rd, VRd vs Rd, and KRd vs VRd) and we analyzed genes that were significantly altered. PV and PG analytics related to these systems associated with renal, nervous, and respiratory AEs were presented below. **Conclusions:** Doublet and triplet therapies like Rd, VRD, and KRd exhibited higher toxicity than V and K in PV. Dexamethasone-containing combinations showed worsened AE profiles. This novel methodology revealing nephro- and neuro-toxicity associations with specific AMDRs can potentially mitigate AEs and improve treatment tolerability.

Introduction: Multiple myeloma (MM) is a diverse disease both clinically and genetically. This study aims to analyze the impact of cytogenetic abnormalities detected through fluorescence in situ hybridization (FISH) and the role of co-segregation on prognosis in newly diagnosed MM patients. **Methods:** We have investigated the presence of t(4;14), t(14;16), 17p deletion, +1q (gain/amplification) and 1p deletion by FISH on CD38 purified plasma cells. The cut-off level for considering a positive result was set at 10% for IGH translocations (fusion/break-apart probes), and 20% for gains and deletions. For +1q, gain was defined as 3 copies (1q gain), and 1q amplification as ≥4 copies (amp1q). Statistical analyses were performed to compare different groups and evaluate progression-free survival (PFS) and overall survival (OS). The Cox proportional hazards regression model was employed to estimate hazard ratios and 95% confidence intervals. **Results:** A total of 1304 patients enrolled in 4 trials (GEM05MAS65, GEM05MENOS65, GEM2010, and GEM2012) were included in the study. The frequencies of genetic abnormalities were: del(17p) in 8%, t(4;14) in 12%, t(14;16) in 3%, +1q in 43%, and del(1p) in 8%. The median follow-up was 61 months. The median PFS was 44 months, and the median OS was not yet reached. Patients with t(4;14) had a shorter PFS (median 28 m vs. 45 m, p< 0.001)) and OS (3-year OS 61% vs. 80%. p< 0.001). It was frequently found in association with other genetic alterations (71% of cases), which significantly worsened its negative impact on survival. However, the presence of t(14;16) did not impact survival. Del(17p) was found to be associated with poor prognosis using a cut-off level of ≥20% positive cells. No significant differences in outcome among the other cutoff groups analyzed (≥30% up to ≥70%) were observed. Patients with ≥80% cells with 17p deletion had a particularly poor prognosis, with a median PFS of just over one year. Co-segregation with other genetic abnormalities did not significantly affect the outcome in patients with del(17p). Patients with + 1q had significantly shorter PFS (36.5 m vs. 53 m, p=0.0001) and OS (81 m vs. NR, p=0.0002). In our series, no significant outcome differences were found between 1q gain and amplifications. Del(1p) was also associated with inferior PFS in the overall series, but no differences in OS were observed. Interestingly, upon analyzing patients with +1q ordel(1p) as the sole abnormality its negative prognostic impact disappeared. **Conclusions:** In conclusion, our study confirmed the prognostic significance of high-risk cytogenetic abnormalities in a large cohort of MM patients. We also demonstrated the importance of considering the co-occurrence of high-risk alterations to accurately assess prognosis. Thus, while del(17p) retains its adverse prognosis even as a solitary abnormality, the negative prognosis of 1q gains was mitigated if this abnormality occured as the sole aberration.

Deep learning-based classifier for malignant plasma cell identification from single-cell RNA-seq data

Sarthak Satpathy[1], William Pilcher[1], Vaishali Prahalad[1], Manoj Bhasin[1]

[1]Emory University

Introduction: Recent characterization of Multiple myeloma (MM) using single-cell profiling has revealed that plasma cells (PCs) exhibit high heterogeneity and are patient-specific. Existing methods for characterizing malignancy in PCs rely on marker-based annotation or CNV detection, which necessitate human intervention and are cumbersome. To overcome this, we have developed an unbiased deep learning (DL)-based method that can automatically identify malignant PCs by analyzing single-cell profiles, leveraging its high accuracy and transferable learning ability. **Methods:** Publicly available single-cell RNA sequencing data of 10,790 MM and 9,329 normal PCs were obtained (GSE193531) for 26 subjects with MM (n=8), smoldering multiple myeloma (SMM) (n=12), and monoclonal gammopathy (MGUS) (n=6), as well as 9 normal bone marrow (NBM) samples. The autoencoder-based DL model was trained and cross-validated on different sets of patients within the training dataset. Model performance was further evaluated on 3,523 normal PCs and 11,656 MM cells from the Human Cell Atlas and studies of MM immune microenvironment characterization. Correlative analysis between predicted malignancy and survival was performed using a Cox regression model. Additionally, gene-regulatory analysis was performed on the gene signature of malignant-classified PCs to gain molecular insights. **Results:** Our autoencoder-based DL model, designed to classify malignant and normal PCs, achieved 100% accuracy on the training and test data. Further independent validation on a different patient set consisting of 6,193 normal and 7,786 malignant cells achieved ~98% accuracy in predicting malignant (F1=0.98) and normal phenotypes (F1=0.98). We applied this model to predict the proportion of malignant PCs in

Deep learning-based classifier for malignant plasma cell identification from single-cell RNA-seq data

Sarthak Satpathy[1], William Pilcher[1], Vaishali Prahalad[1], Manoj Bhasin[1]

[1]Emory University

Introduction: Recent characterization of Multiple myeloma (MM) using single-cell profiling has revealed that plasma cells (PCs) exhibit high heterogeneity and are patient-specific. Existing methods for characterizing malignancy in PCs rely on marker-based annotation or CNV detection, which necessitate human intervention and are cumbersome. To overcome this, we have developed an unbiased deep learning (DL)-based method that can automatically identify malignant PCs by analyzing single-cell profiles, leveraging its high accuracy and transferable learning ability. **Methods:** Publicly available single-cell RNA sequencing data of 10,790 MM and 9,329 normal PCs were obtained (GSE193531) for 26 subjects with MM (n=8), smoldering multiple myeloma (SMM) (n=12), and monoclonal gammopathy (MGUS) (n=6), as well as 9 normal bone marrow (NBM) samples. The autoencoder-based DL model was trained and cross-validated on different sets of patients within the training dataset. Model performance was further evaluated on 3,523 normal PCs and 11,656 MM cells from the Human Cell Atlas and studies of MM immune microenvironment characterization. Correlative analysis between predicted malignancy and survival was performed using a Cox regression model. Additionally, gene-regulatory analysis was performed on the gene signature of malignant-classified PCs to gain molecular insights. **Results:** Our autoencoder-based DL model, designed to classify malignant and normal PCs, achieved 100% accuracy on the training and test data. Further independent validation on a different patient set consisting of 6,193 normal and 7,786 malignant cells achieved ~98% accuracy in predicting malignant (F1=0.98) and normal phenotypes (F1=0.98). We applied this model to predict the proportion of malignant PCs in

sequential samples of MGUS and SMM patients, and found average malignancies of 12.66% and 77.55%, respectively. Furthermore, from our recently published MM immune microenvironment study, our model predicted significantly higher malignancy for rapid progressors (mean 0.688 ± 0.048) compared to non-progressors (mean 0.371±0.039, Welch's t-test, p 1, p0.25), of which 75 were ribosomal genes. Higher malignancy was also correlated with higher cytogenic risk (p< 0.05) and aneuploidy (p< 0.01) in PCs from the MM patients. **Conclusions:** This DL-based model for predicting malignant PCs could prove to be valuable in the prognosis of MM and in assessing the progression kinetics of precursor stages (i.e., MGUS or SMM) to MM. Further evaluation of the accuracy of malignancy prediction based on blood profiles may lead to the development of a less invasive tool for tracking MM to support better outcomes.

Single cell multi-omic correlation of single nucleotide variants, copy number variation and surface epitopes for clonal profiling of myeloma

Adam Sciambi[1], Cedric Dos Santos[2], Yang Li[1], Joanne Nguyen[1], Priyam Priyam[1], Vivek Chopra[2], Habib Hamidi[2], Michael Nixon[3], Yann Nouet[4], Todd Druley[1], Herve Avet-Loiseau[5]

[1]Mission Bio, Inc.; [2]Genentech Inc.; [3]Roche, Inc.; [4]F. Hoffmann-La Roche Ltd.; [5]Oncopole

Introduction: Multiple myeloma (MM) is a cancer of plasma cells with approximately 200,000 new diagnoses each year and a 54% 5-year overall survival rate. As myeloma cells expand, clonal genetic differences lead to relapse due to acquired resistance in 100% of patients, mandating regular, long-term surveillance. Improvements in precision medicine for MM have come from monoclonal antibodies and antibody-drug conjugates that specifically target the offending cells. However, while existing diagnostic modalities offer exquisite sensitivity, they are limited in exploring subclonal genetic changes and putative antibody targets on refractory myeloma cells, leaving the clinician to use their best judgment on salvage therapy. Knowing the actual targets on the refractory disease would better facilitate precision medicine. **Methods:** Using cryopreserved, human MM patient samples processed on the Mission Bio Tapestri platform, we were able to simultaneously quantify subclones by single-cell single nucleotide variants (SNV), copy number variants (CNV), and surface protein analysis. We show complex clonal evolution of MM in individual samples as copy gains and losses were sequentially acquired and correlated with expression changes of MM markers. These single time point samples were thawed from frozen bone marrow mononuclear cells previously enriched for CD38, stained with a 45-plex antibody-oligo cocktail to label common heme-specific surface markers for sequencing analysis, and processed with a 733-plex DNA primer panel that combined whole-genome CNV coverage with MM gene hotspots. **Results:** Across the cases analyzed, complex branching phylogenetic trees were reconstructed with as many as five subclones and clear associated shifts in MM-marker expression. When averaged across subclones, each of the samples had CNV profiles that matched patient records, ranging from a single gene-level copy gain to arm-level gains and losses across the majority. The progression of protein expression within different samples could be mapped together on a single plot and correlated with generally higher MM-markers as subclonal genetic variants were acquired, though occasional branches saw reversal. The fraction of other cell phenotypes, such as T-cells and those with low viability, decreased within subclones as mutational burden grew. The drop in low viability implied improved clonal robustness (at least to handling) with disease progression. **Conclusions:** This high-resolution, single cell assay offers a potential new modality for the diagnosis and surveillance of patients with suspected MGUS, SGUS or high-risk MM. We have demonstrated: 1) exceptional results from cryopreserved human specimens, 2) the ability to use genetic lesion profiling to positively identify subclonal MM and, most importantly, 3) correlate cell surface protein expression of potential therapeutic targets with each clonal and subclonal population.

CoMMsol: a machine learning model for outcome-specific copy number alterations' clonality cut-offs definition in multiple myeloma

Vincenza Solli[1,2], Ajsi Kanapari[1,2], Gaia Mazzocchetti[1,2], Andrea Poletti[1,2], Ilaria Vigliotta[1,2], Marina Martello[1,2], Ignazia Pistis[2], Enrica Borsi[2], Barbara Taurisano[1,2], Silvia Armuzzi[1,2], Lucia Pantani[1,2], Elena Zamagni[1,2], Michele Cavo[2], Carolina Terragna[2]

[1]Department of Medical and Surgical Sciences - University of Bologna, Bologna, Italy; [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Seràgnoli Institute of Hematology, Bologna, Italy

Introduction: Multiple Myeloma (MM) genetic architecture is complex and heterogeneous and includes a vast amount of Copy Number Alterations (CNAs), whose presence and recurrence can be used to stratify patients (pts) into prognostic subgroups. Due to the sub-clonal composition of MM, CNAs call is not trivial, especially when small clonal frequencies should be discriminated from background. At the same time, the set-up of experimental cut-offs is crucial to assess the CNAs prognostic role. To date, a fixed 10% cut-off is commonly employed for all CNAs' call. **Aims:** 1)To employ a machine learning(ML) approach to define the best clonality cut-offs for each CNAs, able to predict for early relapse (ER)(i.e. within 18 months from the start of therapy); 2) to select baseline CNAs most significantly correlated to the achievement of ER. **Methods:** 743 newly diagnosed MM pts with SNPs array-derived genomic data and clinical annotations were included in the study. Analyzes were performed by R Studio 4.1.2 scripts and packages. **Results:** Overall, 155/743pts relapsed within 18 months from the start of therapy. By ML computational approach, we set up a model (named coMMsol) able to select, for each observed CNAs, the best clonality cut-off significantly predictive of ER. Among CNAs called according to this model, the one significantly correlated to ER were amp1q, amp2p, del2p, del12p, del17p, del19p. By stratifying pts according to the presence of at least one of these CNAs, two groups of 249 and 494 pts, either carrying or not ≥1 ER-CNAs were identified,

sequential samples of MGUS and SMM patients, and found average malignancies of 12.66% and 77.55%, respectively. Furthermore, from our recently published MM immune microenvironment study, our model predicted significantly higher malignancy for rapid progressors (mean 0.688 ± 0.048) compared to non-progressors (mean 0.371±0.039, Welch's t-test, p 1, p0.25), of which 75 were ribosomal genes. Higher malignancy was also correlated with higher cytogenic risk (p< 0.05) and aneuploidy (p< 0.01) in PCs from the MM patients. **Conclusions:** This DL-based model for predicting malignant PCs could prove to be valuable in the prognosis of MM and in assessing the progression kinetics of precursor stages (i.e., MGUS or SMM) to MM. Further evaluation of the accuracy of malignancy prediction based on blood profiles may lead to the development of a less invasive tool for tracking MM to support better outcomes.

Introduction: Multiple myeloma (MM) is a cancer of plasma cells with approximately 200,000 new diagnoses each year and a 54% 5-year overall survival rate. As myeloma cells expand, clonal genetic differences lead to relapse due to acquired resistance in 100% of patients, mandating regular, long-term surveillance. Improvements in precision medicine for MM have come from monoclonal antibodies and antibody-drug conjugates that specifically target the offending cells. However, while existing diagnostic modalities offer exquisite sensitivity, they are limited in exploring subclonal genetic changes and putative antibody targets on refractory myeloma cells, leaving the clinician to use their best judgment on salvage therapy. Knowing the actual targets on the refractory disease would better facilitate precision medicine. **Methods:** Using cryopreserved, human MM patient samples processed on the Mission Bio Tapestri platform, we were able to simultaneously quantify subclones by single-cell single nucleotide variants (SNV), copy number variants (CNV), and surface protein analysis. We show complex clonal evolution of MM in individual samples as copy gains and losses were sequentially acquired and correlated with expression changes of MM markers. These single time point samples were thawed from frozen bone marrow mononuclear cells previously enriched for CD38, stained with a 45-plex antibody-oligo cocktail to label common heme-specific surface markers for sequencing analysis, and processed with a 733-plex DNA primer panel that combined whole-genome CNV coverage with MM gene hotspots. **Results:** Across the cases analyzed, complex branching phylogenetic trees were reconstructed with as many as five subclones and clear associated shifts in MM-marker expression. When averaged across subclones, each of the samples had CNV profiles that matched patient records, ranging from a single gene-level copy gain to arm-level gains and losses across the majority. The progression of protein expression within different samples could be mapped together on a single plot and correlated with generally higher MM-markers as subclonal genetic variants were acquired, though occasional branches saw reversal. The fraction of other cell phenotypes, such as T-cells and those with low viability, decreased within subclones as mutational burden grew. The drop in low viability implied improved clonal robustness (at least to handling) with disease progression. **Conclusions:** This high-resolution, single cell assay offers a potential new modality for the diagnosis and surveillance of patients with suspected MGUS, SGUS or high-risk MM. We have demonstrated: 1) exceptional results from cryopreserved human specimens, 2) the ability to use genetic lesion profiling to positively identify subclonal MM and, most importantly, 3) correlate cell surface protein expression of potential therapeutic targets with each clonal and subclonal population.

Introduction: Multiple Myeloma (MM) genetic architecture is complex and heterogeneous and includes a vast amount of Copy Number Alterations (CNAs), whose presence and recurrence can be used to stratify patients (pts) into prognostic subgroups. Due to the sub-clonal composition of MM, CNAs call is not trivial, especially when small clonal frequencies should be discriminated from background. At the same time, the set-up of experimental cut-offs is crucial to assess the CNAs prognostic role. To date, a fixed 10% cut-off is commonly employed for all CNAs' call. **Aims:** 1)To employ a machine learning(ML) approach to define the best clonality cut-offs for each CNAs, able to predict for early relapse (ER)(i.e. within 18 months from the start of therapy); 2) to select baseline CNAs most significantly correlated to the achievement of ER. **Methods:** 743 newly diagnosed MM pts with SNPs array-derived genomic data and clinical annotations were included in the study. Analyzes were performed by R Studio 4.1.2 scripts and packages. **Results:** Overall, 155/743pts relapsed within 18 months from the start of therapy. By ML computational approach, we set up a model (named coMMsol) able to select, for each observed CNAs, the best clonality cut-off significantly predictive of ER. Among CNAs called according to this model, the one significantly correlated to ER were amp1q, amp2p, del2p, del12p, del17p, del19p. By stratifying pts according to the presence of at least one of these CNAs, two groups of 249 and 494 pts, either carrying or not ≥1 ER-CNAs were identified,

sequential samples of MGUS and SMM patients, and found average malignancies of 12.66% and 77.55%, respectively. Furthermore, from our recently published MM immune microenvironment study, our model predicted significantly higher malignancy for rapid progressors (mean 0.688 ± 0.048) compared to non-progressors (mean 0.371±0.039, Welch's t-test, p 1, p0.25), of which 75 were ribosomal genes. Higher malignancy was also correlated with higher cytogenic risk (p< 0.05) and aneuploidy (p< 0.01) in PCs from the MM patients. **Conclusions:** This DL-based model for predicting malignant PCs could prove to be valuable in the prognosis of MM and in assessing the progression kinetics of precursor stages (i.e., MGUS or SMM) to MM. Further evaluation of the accuracy of malignancy prediction based on blood profiles may lead to the development of a less invasive tool for tracking MM to support better outcomes.

Introduction: Multiple Myeloma (MM) genetic architecture is complex and heterogeneous and includes a vast amount of Copy Number Alterations (CNAs), whose presence and recurrence can be used to stratify patients (pts) into prognostic subgroups. Due to the sub-clonal composition of MM, CNAs call is not trivial, especially when small clonal frequencies should be discriminated from background. At the same time, the set-up of experimental cut-offs is crucial to assess the CNAs prognostic role. To date, a fixed 10% cut-off is commonly employed for all CNAs' call. **Aims:** 1)To employ a machine learning(ML) approach to define the best clonality cut-offs for each CNAs, able to predict for early relapse (ER)(i.e. within 18 months from the start of therapy); 2) to select baseline CNAs most significantly correlated to the achievement of ER. **Methods:** 743 newly diagnosed MM pts with SNPs array-derived genomic data and clinical annotations were included in the study. Analyzes were performed by R Studio 4.1.2 scripts and packages. **Results:** Overall, 155/743pts relapsed within 18 months from the start of therapy. By ML computational approach, we set up a model (named coMMsol) able to select, for each observed CNAs, the best clonality cut-off significantly predictive of ER. Among CNAs called according to this model, the one significantly correlated to ER were amp1q, amp2p, del2p, del12p, del17p, del19p. By stratifying pts according to the presence of at least one of these CNAs, two groups of 249 and 494 pts, either carrying or not ≥1 ER-CNAs were identified,

the first one with significantly shorter PFS and OS (PFS HR 2.15, CI 1.79-2.58 p< 0001, OS HR 2.37, CI 1.86-3.02 p< 0.0001). The worse prognostic impact was observed even in the absence of both amp1q and del17p, observed in 38/249 (15%) pts (PFS HR 2.57, CI 1.79-3.70 p< 00001, OS HR 2.49, CI 1.57-3.94 p=0.0001), compared to 494pts. The risk of relapse defined by the presence of ≥1 ER-CNAs was independent from those conferred both by R-IIS 3 (HR=1.51 CI 0.17-2.39-2.2; p=0.01) and by low quality (< stable disease) first-line best clinical response (HR=2.59 CI0.33-2.84 p=0.004). Notably, the type of induction therapy was not descriptive in this multivariate model, suggesting that ER is strongly related to pts' baseline genomic architecture, and not to induction therapy they were provided to. **Conclusions:** ML approach allowed to define CNAs-specific dynamic clonality cut-offs, improving the CNAs calls' accuracy to identify MM pts with the highest probability to ER. The use of these ER-related cut-offs pinpointed few CNAs, whose presence at baseline is highly predictive of ER, including amp2p, del2p, del12p, and del19p, whose biological role in MM needs further investigations. As being outcome-dependent, the coMMsol method is dynamic and might be adjusted according to the selected outcome variable of interest (e.g. MRD-negativity) thus providing outcome-specific clonality cut-offs. Introduction: Oncogenic RAS mutations are frequent genomic drivers in MM. Specific inhibitors of the G12C and G12D KRAS mutants are clinically active in solid tumors with these mutations, which however are rare in MM patients. Nevertheless, we studied these inhibitors in G12C/D KRAS mutant MM cells to assess its functional consequences and potential mechanisms of escape from KRAS inhibition, and facilitate potential similar efforts when other KRAS mutations, more prevalent in MM, may become targetable in the future. **Methods:** We assessed the response of G12C (KHM1B, XG7) and G12D (KARPAS620, KP6) KRAS mutant MM cell lines to G12C- (MRTX1257) and G12D- (MRTX1133) specific KRAS inhibitors (within the concentration range achievable in patients with solid tumors) both as single agents and in combination with clinically established anti-MM agents. Effects of these inhibitors on cell viability and proliferation (bioluminescence assays), signaling downstream of KRAS (Western blots) and transcriptional networks (RNA-seq) were analyzed. Induction of cell death, apoptosis and cell cycle distribution were assessed by flow cytometry. Genome-scale CRISPR activation studies identified genes whose gain-of-function (GOF) can enhance or suppress the MM cell response to KRAS inhibition. **Results:** Both KRAS inhibitors exhibited potent and mutant-specific activity in their respective MM lines (IC50 in the range of 5-150 nM after 3-7d treatment), with effective abrogation of downstream phosphorylation for MAPK and AKT pathway members. MRTX1257 predominantly reduced proliferation of XG7 cells, whereas MRTX1133 led to potent cell death induction of KARPAS620 and KP6 cells. Combinations of MRTX1257 with investigational or established anti-MM drugs, including melphalan, bortezomib or pomalidomide, led to no antagonism and in some cases – including combination with MEKi trametinib – caused supra-additive effects. MRTX1257 downregulated known Ras effector genes (e.g., ETV4, ETV5), negative regulators of Ras signaling (e.g., DUSP6, SPRY4, reflecting a Ras-driven negative feedback loop controlling expression of these genes) and genes involved in cell cycle regulation (e.g., D-type cyclin), anti-apoptosis, and DNA replication/repair; and upregulated genes involved in cell cycle arrest and stress responses. In CRISPR activation studies, GOF of KRAS itself, upstream surface receptors (e.g., EGFR), SHOC2 (which encodes for a scaffold protein serving as positive regulator of RAS-MAPK signaling) were among key "hits" promoting MM cell escape from KRAS inhibitor treatment. **Conclusions:** This study documents mutant-specific activity of KRAS G12C and G12D inhibitors in MM cells and provides functional insights into the pharmacological inhibition of KRAS in MM. Ongoing in vitro and in vivo studies are examining the targeting of genes/pathways associated with escape from KRAS inhibition, as a framework for future efforts to improve the rates, depth and durability of responses to KRAS inhibition in MM.

Combinations of MRTX1257 with investigational or established anti-MM drugs, including melphalan, bortezomib or pomalidomide, led to no antagonism and in some cases – including combination with MEKi trametinib – caused supra-additive effects. MRTX1257 downregulated known Ras effector genes (e.g., ETV4, ETV5), negative regulators of Ras signaling (e.g., DUSP6, SPRY4, reflecting a Ras-driven negative feedback loop controlling expression of these genes) and genes involved in cell cycle regulation (e.g., D-type cyclin), anti-apoptosis, and DNA replication/repair; and upregulated genes involved in cell cycle arrest and stress responses. In CRISPR activation studies, GOF of KRAS itself, upstream surface receptors (e.g., EGFR), SHOC2 (which encodes for a scaffold protein serving as positive regulator of RAS-MAPK signaling) were among key "hits" promoting MM cell escape from KRAS inhibitor treatment. **Conclusions:** This study documents mutant-specific activity of KRAS G12C and G12D inhibitors in MM cells and provides functional insights into the pharmacological inhibition of KRAS in MM. Ongoing in vitro and in vivo studies are examining the targeting of genes/pathways associated with escape from KRAS inhibition, as a framework for future efforts to improve the rates, depth and durability of responses to KRAS inhibition in MM.

Introduction: Extensive research has been conducted to elucidate the molecular mechanisms underlying the pathophysiology of Multiple Myeloma. The role of BMPs (Bone Morphogenetic Proteins) and their downstream gene expression regulators, such as Smad (Small Mother Against Decapentaplegic) transcription factors in the molecular-level imbalance of bone metabolism remains uncertain. Most studies were conducted in preclinical models which did not account the effect of the human microenvironment. In our study, we investigated the transcriptional levels of BMP-2, BMP-6 and Smad6 in human bone marrow aspirates. **Methods:** Our study included 39 patients (19 newly diagnosed patients, 20 refractory/relapsed patients) and 10 controls (patients with other non-Hodgkin lymphomas without bone marrow infiltration). RNA isolation of bone marrow mononuclear cells was conducted using the Omega Biotek® EZNA Total RNA kit, and RNA quantification by using a Nanodrop2000® spectrophotometer. cDNA synthesis was performed using the QuantiTect® Reverse Transcription Kit (50), Qiagen®. The primers for BMP-2, BMP-6, and Smad6 were designed by Qiagen®. B2-microglobulin was the reference gene. The RT-PCR was conducted using the QuantiNova SYBR Green PCR kit from Qiagen®. We validated our PCR products using gel electrophoresis and melt curves. PCR reactions were conducted in duplicate. Differential expression was calculated using the ΔΔCt method and graphs were created using the GraphPad Prism program. **Results:** There was no significant difference in gene expression of BMP-2 between controls and newly diagnosed patients (p=ns), and relapsed patients (p=ns). On the other hand, BMP-6 was found to be increased by 4.8 times in newly diagnosed patients (p = 0.0004) and 2.56 times in relapse patients (p = 0.0226). Finally, for Smad6, no statistically significant difference was found between controls and newly diagnosed patients (p = 0.2861), but it decreased by 1.5 times in relapsed patients (p = 0.012). **Conclusions:** BMPs and, to a lesser extent, Smads have been investigated in the past as potent regulators of bone metabolism in Multiple Myeloma, mostly in preclinical setting. Our findings in bone marrow aspirates of myeloma patients suggest that BMP-2 did not show a significant difference between controls and patients, indicating that it may not have a significant impact on bone metabolism. Conversely, the increased BMP-6 levels may indicate either increased fixation in the matrix and an inability to act through a positive feedback mechanism or involvement in the induction of genes that inhibit apoptosis. Smad6 expression is reduced in R/R patients, suggesting that MM cells have developed mechanisms of dependence on BMPs and induces Smad6 repression through alternative signaling pathways or inhibitors. The role of BMPs and Smads still appears unclear; further experiments may elucidate their role on signaling pathways in MM.

Introduction: Chromosome 17p deletion (del(17p)), a high-risk feature in multiple myeloma (MM), is typically monoallelic. Its biological/clinical significance involves complete loss-of-function (LOF) of the tumor suppressor gene (TSG) TP53, through deletion of one TP53 copy and inactivating mutation (double-hit lesion) of the other copy, whereas biallelic loss is rare. While this combined copy number (CN) loss and mutation of TP53 appear to be favored over biallelic deletion of TP53/17p13, the mechanisms for this phenomenon have not been elucidated. We hypothesized that 17p13 contains multiple genes essential for MM cell survival, thereby favoring retention of at least one copy of this region in MM cells. **Methods:** We curated genes residing in chr17p13 through the UCSC Genome Browser and examined their essentiality scores (CHRONOS 22Q2 or CERES scores from DepMap) in 19 MM cell lines (including 3 TP53 wild-type [WT] lines), to identify genes are that "core"/"pan-cancer" dependencies (CERES/CHRONOS scores 90% of tumor lines across all lineages); preferentially essential for MM cells (compared with all non-MM lines) vs recurrently (but not preferentially) essential for MM cells vs non-essential. Functional assessment of key genes was complemented by in silico analyses of MMRF CoMMpass data (IA22, n=1050) and CRISPR-based LOF studies (of individual genes or in pooled format) or cDNA-overexpression studies. **Results:** Of the 108 chr17p13 genes, we identified 7 "core" essential genes (RPL26, AURKB, EIF4A1, MED31, EIF5A, TRAPPC1, ELP5), 2 MM-preferential dependencies (the glycosylation regulator MPDU1, and the purine biosynthesis gene PFAS); and other genes (e.g. CTDNEP1, CTC1) that were recurrent essentiality (e.g. in >3/19 MM lines). Enrichment of CRISPR KO was observed for TP53 in 2 of 3 TP53 WT MM lines; and 1 for candidate TSG, SAT2. This latter gene had enrichment of its CRISPR-KO in a pooled screen in NCI-H929

Introduction: Chromosome 17p deletion (del(17p)), a high-risk feature in multiple myeloma (MM), is typically monoallelic. Its biological/clinical significance involves complete loss-of-function (LOF) of the tumor suppressor gene (TSG) TP53, through deletion of one TP53 copy and inactivating mutation (double-hit lesion) of the other copy, whereas biallelic loss is rare. While this combined copy number (CN) loss and mutation of TP53 appear to be favored over biallelic deletion of TP53/17p13, the mechanisms for this phenomenon have not been elucidated. We hypothesized that 17p13 contains multiple genes essential for MM cell survival, thereby favoring retention of at least one copy of this region in MM cells. **Methods:** We curated genes residing in chr17p13 through the UCSC Genome Browser and examined their essentiality scores (CHRONOS 22Q2 or CERES scores from DepMap) in 19 MM cell lines (including 3 TP53 wild-type [WT] lines), to identify genes are that "core"/"pan-cancer" dependencies (CERES/CHRONOS scores 90% of tumor lines across all lineages); preferentially essential for MM cells (compared with all non-MM lines) vs recurrently (but not preferentially) essential for MM cells vs non-essential. Functional assessment of key genes was complemented by in silico analyses of MMRF CoMMpass data (IA22, n=1050) and CRISPR-based LOF studies (of individual genes or in pooled format) or cDNA-overexpression studies. **Results:** Of the 108 chr17p13 genes, we identified 7 "core" essential genes (RPL26, AURKB, EIF4A1, MED31, EIF5A, TRAPPC1, ELP5), 2 MM-preferential dependencies (the glycosylation regulator MPDU1, and the purine biosynthesis gene PFAS); and other genes (e.g. CTDNEP1, CTC1) that were recurrent essentiality (e.g. in >3/19 MM lines). Enrichment of CRISPR KO was observed for TP53 in 2 of 3 TP53 WT MM lines; and 1 for candidate TSG, SAT2. This latter gene had enrichment of its CRISPR-KO in a pooled screen in NCI-H929

cells (not studied in DepMap). Supporting this result, targeted CRISPR-KO and overexpression of SAT2 increased vs decreased, the growth of H929 cells and their sensitivity to bortezomib or lenalidomide treatment. CN losses, all monoallelic, of SAT2 were observed in 11.4% of samples, suggesting that the preference for monoallelic CN loss of 17p13 applies not only for TP53 but also other putative TSGs of this locus. In contrast to 17p13, TSGs with recurrent biallelic deletion (e.g. CDKN2C on chr1p32; CN loss in 12% of pts, with 23/152 [15%] biallelic events) have fewer essential genes and longer genomic distances from them (e.g. MPDU1 is within 85kbp of TP53, while the closest essential gene to CDKN2C (BTF3L4) is >1Mbp away). **Conclusions:** 17p13.1 contains several "core" or MM-preferential (MPDU1, PFAS) dependencies, some located close to TP53. This may explain why monoallelic del(17p) events predominate in MM and suggests that therapies targeting MPDU1, PFAS or other dependencies of this locus may have applications for high-risk 17p(del) MM.

Introduction: Multiple myeloma (MM) is a clinically diverse disease with a heterogeneous genomic architecture. Recent improvements in MM treatment outcomes are due to better diagnosis and new therapies. Grasping MM biology and genetics can enhance patient care and expedite drug approval for investigational treatments. Patients are currently stratified into risk groups based on clinical prognosis and cytogenetic markers. Despite advances in therapy, most MM patients will still relapse or become refractory to treatment. There are patient groups that could benefit from alternative therapeutic options. We aimed to identify these groups by analyzing MM patients' clinical and molecular profiles via exome and RNA sequencing and ex vivo drug sensitivity testing. **Methods:** We collected bone marrow aspirates from 173 MM patients. CD138+ cells from these samples were selected, and somatic alterations identified via exome sequencing of DNA and matched skin biopsies. We performed RNA sequencing on CD138+ cells (n = 145) for differential gene expression study and screened them against 142 compounds in a 10,000-fold concentration range. In parallel, we performed proteomics analysis on 39 of these samples using mass spectrometry, providing protein expression data for up to 2753 proteins. **Results:** Our analysis revealed distinct transcriptional and phenotypic consequences of TP53 mutation and del(17p). Mutation to TP53 was associated with upregulation of genes related to the cell cycle, including G2M checkpoint and E2F targets, and the downregulationg of genes controlled by NF-kB in response to TNF. Conversely, samples with del(17p) were characterized by an upregulation of TNF signaling via NF-kB and other immune response pathways. Interestingly, samples with both TP53 mutation and del(17p) exhibited an even more pronounced downregulation of NF-kB compared to solely TP53-mutated samples, while maintaining reduced expression of response to interferon alpha and gamma. These distinct molecular profiles translated into unique drug sensitivity patterns. CD138+ cells with mutation in TP53 showed increased sensitivity to mTOR/PI3K, IGF1R inhibitors and JAK inhibitors ex vivo, an effect that was observable irrespective of the co-occurrence of del(17p). Preliminary proteomic analyses of cell signaling pathways is ongoing. **Conclusions:** Our findings suggest that MM patients with TP53 mutation may benefit from targeted therapies involving mTOR/PI3K, IGF1R and JAK inhibitors, regardless of whether del(17p) is present or not. Improved understanding of those mechanisms would allow for a more nuanced patient stratification that factors in TP53 mutation status and del17p, offering promise for more personalized therapeutic strategies for MM patients. Further research is warranted to explore potential therapeutic options tailored to the unique genetic and response profiles of patients with TP53 mutation and del17p.

Data suggests adverse event (AE) profiles are orchestrated by certain associated genes. The purpose of this study is to explore the interplay of genes, drug regimens and AEs and provide genetic evidence for a linkage between regimen(s) and the presence of an AE. **Methods:** We examined a group of AMDRs retrieved from the FDA AE Reporting System, MM patient data from the MMRF CoMMpass study and MM patient cell line gene

expression data. Drug-associated genes were obtained from the Drug Gene Interaction Database. Genes were then imported to the Online Mendelian Inheritance in Man (OMIM) to search for existing AE clinical features. AE clinical features were then linked to the defined Medical Dictionary for Regulatory Activities (MedDRA) hierarchy. Gene-gene interaction was also determined through the Search Tool for the Retrieval of Interacting Genes/Proteins (STRING). **Results:** Our results suggested that gene expression is highly influenced by multiple AMDRs from the combinations of carfilzomib, bortezomib, lenalidomide or dexamethasone. We found multiple pathways were differentially expressed (signaling pathways, such as eNOS, PI3K, NFAT, NFkB and MAPK), when carfilzomib-lenalidomide-dexamethasone, bortezomib-lenalidomide-dexamethasone, and lenalidomide-dexamethasone regimens were involved, raising the possibility of associations between these pathways and specific AE profiles including cardiovascular disorders, neoplasm, or other serious AEs, see Table for pharmacovigilance (PV) and pharmacogenomics (PG). The occurrence of pericardial disorders increased with high confidence when carfilzomib-lenalidomide-dexamethasone was administered. We also found that the carfilzomib-lenalidomide-dexamethasone regimen compared with other treatments such as lenalidomide-dexamethasone or bortezomib-lenalidomide-dexamethasone were more closely associated with multiple pathways such as cardiac hypertrophy signaling, thrombin signaling, coagulation system, and HIF1a signaling which were likely to be the genetic signaling factors concomitant with presentations of heart failure, cardiac arrhythmias or other cardio-toxicities such as pulmonary hypertension, tumor progression and metastasis. **Conclusions:** Understanding the genomic basis of specific drug-AE combinations could reveal the molecular mechanisms underlying drug-gene-AE associations and characterize the causality of AE and drug use. Our study offers insights for predicting treatment responses when considering alternative agents in MM.

Introduction: Approximately 15-20% of newly diagnosed multiple myeloma (MM) display high-risk features with a poor response to current treatment options and shorter survival than the standard-risk group. Genetic events are used to stratify high-risk MM (hrMM) (e.g. Amp1q). Two hrMM gene signatures, UAMS-70 and EMC-92 (SKY92), have been independently developed and validated to predict poor clinical outcomes. Within the hrMM group, two ultra hrMM subgroups were identified as double hit hrMM (with >2 high-risk cytogenetic abnormalities) and functional hrMM, who did not have hrMM-associated genomic alterations but were refractory to induction therapy or had early relapse within 12 months. These ultra hrMM had an overall worse prognosis than genetically defined hrMM. Clearly, novel approaches are required for treating hrMM, particularly ultra hrMM. However, the lack of mouse models recapitulating hrMM and ultra-hrMM has been a barrier in these challenging settings. Activation of a human MYC transgene in germinal center B cells induces a highly penetrant, but relatively indolent MM in primary Vk*MYC mice. Subsequent selection via transplantation and bortezomib (Btz) treatment established transplantable t-Vk*MYC lines (e.g. t-Vk12653) that shows reduced response to Btz in vivo. We recently generated a highly malignant MM mouse model driven by GC expression of hMYC transgene and endogenous NRASQ61R (named "VQ mice"). **Methods:** We performed genomic and transcriptomic profiling of MM models using whole exome sequencing, copy number variation analysis, and RNA-Seq. **Results:** We report that Group A VQ MM and t-Vk12653 share similar transcriptome and several hrMM features, including hyperproliferation, extramedullary disease, exhaustion of CD4 and CD8 T cells, and partial response to Btz treatment. In comparison to control plasma cells, they express higher EMC-92 hrMM scores but not UAMS-70 hrMM gene signature. Compared to Group A VQ and t-Vk12653 MM models, Group B VQ expresses additional hrMM and ultra hrMM features, including downregulation of Fam46c, expression of UAMS-70 and EMC-92 hrMM gene signatures and Amp1q-associated PBX1-FOXM1 gene signatures, upregulation of cancer growth pathways associated with functional hrMM, and de novo resistance to venetoclax in vitro and to Btz and anti-TIGIT immune checkpoint blockade in vivo. Our results suggest that Group A VQ MM and t-Vk12653 may represent Revised International Staging System (R-ISS) Stage III MM without ultra hrMM, while Group B VQ represent R-ISS Stage III MM with ultra hrMM features. Interestingly, trametinib (Tra), an FDA-approved MEK inhibitor, is the only single agent we tested so far that significantly prolongs the survival of both Group A and B VQ

expression data. Drug-associated genes were obtained from the Drug Gene Interaction Database. Genes were then imported to the Online Mendelian Inheritance in Man (OMIM) to search for existing AE clinical features. AE clinical features were then linked to the defined Medical Dictionary for Regulatory Activities (MedDRA) hierarchy. CD38 targeting in multiple myeloma

Andrea Abel[1], Laia Querol Cano[1], Annemiek van Spriel[1], Roel Hammink[1], Martin ter Beest[1]

[1]Radboud Institute for Molecular Life Sciences (RIMLS)

Introduction: Despite recent advances in cancer immunotherapies targeting specific tumor proteins, there is a lack of response in patients that cannot be always explained by the expression levels of these targets. We hypothesize that the organization of the targeted proteins on the surface of the tumor cells plays a key role in antibody accessibility in the crowded membrane, and therefore in the effectiveness of these immunotherapies. CD38 is a glycoprotein highly expressed in MM cells, which has postulated it as a therapeutic target using clinical antibodies in MM patients. The most effective clinical antibody is Daratumumab, which presents a remarkable complement dependent cytotoxicity (CDC) effect. We are interested in studying CD38 organization on the surface of multiple myeloma (MM) cells, since we hypothesize that if CD38 is in a more clustered organization rather than randomly distributed, this will facilitate Daratumumab binding, as well as the IgG hexamer formation needed for CDC-mediated tumor cell killing. Similarly, we also aim to unravel the mechanisms determining CD38 membrane organization on MM. **Methods:** We study CD38 organization at the surface of Daratumumab resistant and sensitive MM cell line models combining advance confocal microscopy. Furthermore, to prove our hypothesis we also artificially modulate CD38 clustering using nanofilaments containing Daratumumab antibodies and optogenetics, which is a novel method to modulate protein clustering/distribution using light, which we expect will translate into an enhanced Daratumumab-mediated CDC killing. To characterize the mechanisms that determine CD38 organization, we are exploring the role of the actin network, as well as the role of membrane organizers such as Tetraspanins and Galectins. This is being studied by microscopy and immunoprecipitation followed by mass spectrometry. **Results:** Our confocal analysis has revealed that both CDC sensitive and resistant MM lines present a similar number of CD38 clusters, although these appear to be larger in our sensitive cell models. We have also seen that the actin network and galectins seem to play a role in CD38 organization. We have successfully immunoprecipitated CD38 and are waiting for the Mass Spectrometry results to dive into the binding partners of CD38. **Conclusions:** CD38 is organized in clusters, which appear to be bigger in the CDC sensitive cells, correlating with our hypothesis that a more clustered organization of CD38 leads to an enhanced CDC effect of Daratumumab. Ongoing experiments with the clustering modulators, both intracellularly and extracellularly, will confirm whether enhancing CD38 clustering also leads to an enhanced Daratumumab-mediated tumor cell killing. In parallel, the actin network and galectins appear to be playing a role in determining CD38 surface organization. Moreover, identifying CD38 binding partners at the plasma membrane of MM cells will shed light into the mechanisms governing its distribution and open novel avenues to modulate its clustering.

Introduction: Patients with multiple myeloma (MM) have been a highly vulnerable population during the COVID-19 pandemic, with an attenuated response to initial vaccinations. Whilst studies have reported the immune response to COVID-19 vaccination in MM patients at isolated time points, little is known about how immunity evolves over successive doses, the effect of the fourth dose and the predictors of poor response. Here, we report results of a longitudinal study that aimed to understand the dynamics of immune responses to doses 2-4 of COVID-19 vaccination in MM. **Methods:** We conducted a national prospective study to investigate COVID-19 immunity acquired by infection or vaccination in patients with MM. The study was open from December 2020 to October 2022 to any UK resident with a diagnosis of MM. The online Rare UK Diseases Study (RUDY) digital platform was used to obtain informed consent and patient-reported clinical details. Patients provided up to three longitudinal serum samples taken ≥3 weeks following doses 2-4. COVID-19 spike (S) and nucleocapsid (N) IgG antibodies were measured by turbidimetry (Abbott), with positive values taken as >1.4 IU/mL and >50 IU/mL, respectively. Collected heparin samples were used to isolate peripheral blood mononuclear cells (PBMCs) and perform a S-protein interferon gamma release assay (IGRA) (Oxford Immunotec T IGRA) to quantify COVID-19-specific effector T cells, with positive results defined as >8 interferon gamma-releasing cells/1 million PBMCs.

mice. Its survival benefit is only observed in immunocompetent but not in immunodeficient NSG mice, suggesting that Tra functions through an intact immune system. **Conclusions:** Our study provides a strong rational to develop Tra-based immunotherapies for treating RAS-driven hrMM and ultra hrMM.

Introduction: Patients with multiple myeloma (MM) have been a highly vulnerable population during the COVID-19 pandemic, with an attenuated response to initial vaccinations. Whilst studies have reported the immune response to COVID-19 vaccination in MM patients at isolated time points, little is known about how immunity evolves over successive doses, the effect of the fourth dose and the predictors of poor response. Here, we report results of a longitudinal study that aimed to understand the dynamics of immune responses to doses 2-4 of COVID-19 vaccination in MM. **Methods:** We conducted a national prospective study to investigate COVID-19 immunity acquired by infection or vaccination in patients with MM. The study was open from December 2020 to October 2022 to any UK resident with a diagnosis of MM. The online Rare UK Diseases Study (RUDY) digital platform was used to obtain informed consent and patient-reported clinical details. Patients provided up to three longitudinal serum samples taken ≥3 weeks following doses 2-4. COVID-19 spike (S) and nucleocapsid (N) IgG antibodies were measured by turbidimetry (Abbott), with positive values taken as >1.4 IU/mL and >50 IU/mL, respectively. Collected heparin samples were used to isolate peripheral blood mononuclear cells (PBMCs) and perform a S-protein interferon gamma release assay (IGRA) (Oxford Immunotec T IGRA) to quantify COVID-19-specific effector T cells, with positive results defined as >8 interferon gamma-releasing cells/1 million PBMCs.

Results: In total, 141 MM patients (median age 66.6 years, 45% female) provided three longitudinal samples following doses 2-4, which were assayed for humoral (n=138) and T-cell (n=61) immune responses. Median Anti-S titres increased from post-2nd (1,065 IU/mL; 93% positive) to post-3rd (6,024 IU/mL; 96% positive) to post-4th (11,179 IU/mL; 98% positive) doses [p< 0.0001]. Longitudinal Anti-S responses were greater in those with a positive T-spot [p< 0.05] or previous natural COVID-19 infection [p< 0.001] and positively correlated with serum IgM [r=0.39-0.44, p< 0.0001]. In comparison, positive T-cell IGRA responses to S-antigen were observed in 62%, 56% and 70% of patients following doses 2-4, respectively. IGRA responses were stronger in patients who had received a mix of recombinant protein and mRNA-based vaccines (compared to mRNA-based alone) [p< 0.01] and positively correlated with lymphocyte count after four doses [r=0.35, p=0.0014]. Both poor myeloma disease status (as defined by International Myeloma Working Group response group) and concurrent anti-CD38/BCMA therapy predicted lower Anti-S and IGRA responses. **Conclusions:** In summary, our data support a robust humoral and cellular immune response to COVID-19 booster doses, including in those with an initial poor response. Our data establish the laboratory and clinical profile of poor vaccine responders, that could be targeted for more intensive COVID-19 risk management, and provide insights to interrogate the biological basis of variable immunity in MM.

Introduction: Bivalent (Ancestral and Omicron BA.4/BA.5) mRNA booster vaccines have been deployed starting in Fall of 2022 to provide continued immunity against the antigenically diverse Omicron variants. We analyzed the immune responses to bivalent booster vaccination in Multiple Myeloma (MM) patients and identified a subset of patients with suboptimal vaccine responses necessitating further investigation into the underlying immune mechanisms. **Methods:** We studied the humoral and cellular immune responses before and after bivalent booster immunization in 44 MM patients. Spike binding IgG antibody levels were measured by ELISA (FDA EUA approved Kantaro). Immune profiling was performed using high-dimensional flow cytometry. The frequencies of dendritic cells (DCs), B cells, Natural Killer (NK) cells and T follicular help cells (TFH) were compared between responders and non-responders. Additionally, we measured spike specific T cell function using the QuantiFERON SARS-CoV-2 (Qiagen) assay as well as flow cytometry-based T cell assays quantifying interferon-gamma (IFNg) production. **Results:** We stratified the antibody responses from 44 MM patients post vaccination into non responders (100 AU/mL, n=36, post vaccine: 281 AU/mL). All non-responders were either on anti-B cell maturation antigen (BCMA) bispecific or anti-CD38 directed therapy. Non-responders exhibited a deficiency in several components of the immune machinery expressing CD38 and BCMA responsible for the production of the humoral and cellular responses. After bivalent vaccination, non-responders exhibited lower frequency of cDCs (p< 0.01), B Cells (p< 0.05) and activated TFH cells (p< 0.05). Furthermore, immature NK cells were the predominant population in non-responders while responders had more cytotoxic mature NK phenotype (p< 0.05) after bivalent vaccination. T cell responses to SARS-CoV-2 correlated with spike binding antibody levels: Non responders also had reduced T cell activity reinforcing the notion that T cell fail to compensate in MM patients. Of note, QuantiFERON SARS-CoV-2 Ag1/Ag2 results correlated with Ancestral strain IFNg production measured by FACS-based T cell assays (R2 = 0.52, p = 0.013). **Conclusions:** Our study highlights the variability of the immune response to bivalent COVID-19 vaccination in MM patients. A subset of MM patients receiving anti-CD38 and anti-BCMA therapy develop defects in cDCs, B cells, NK cells and TFH cells, thereby unable to develop antibody and T cell responses to SARS-CoV-2 vaccinations. Our results indicate that the QuantiFERON SARS-CoV-2 assay could be deployed for clinical use bridging the need for suitable laboratory tests to measure SARS-CoV-2 specific T cell responses. Ongoing studies will determine whether the compromised immune machinery and reduced T cell activity identified here can discriminate patients at high risk for infectious complications from anti-BCMA therapies.

Immunological aging is associated with worse clinical outcome in elderly newly diagnosed multiple myeloma patients

Wassilis Bruins[1], Carolien Duetz[1], Kaz Groen[1], Charlotte Korst[1], A. Vera de Jonge[1], Christie Verkleij[1], Rosa Rentenaar[1], Meliha Cosovic[1], Niels van de Donk[1,2], Sonja Zweegman[1], Tuna Mutis[1]

Introduction: Multiple myeloma (MM) typically affects the elderly, with a median age at diagnosis of 69 years. In healthy individuals, aging negatively affects the functional fitness of immune effector cells. However, the impact of aging on the immune system in MM patients remains largely unclear. We therefore profiled the phenotype of T and NK cells related to age and frailty status. Within the older patients, we then sought for the existence of patients with a younger immune profile, and evaluated whether this impacted survival. **Methods:** 261 newly diagnosed MM patients were included among which younger (range 34-65 years) and older (range 66-92 years) patients retrieved from the HO131 (EudraCT: 2014-004781-

Results: In total, 141 MM patients (median age 66.6 years, 45% female) provided three longitudinal samples following doses 2-4, which were assayed for humoral (n=138) and T-cell (n=61) immune responses. Median Anti-S titres increased from post-2nd (1,065 IU/mL; 93% positive) to post-3rd (6,024 IU/mL; 96% positive) to post-4th (11,179 IU/mL; 98% positive) doses [p< 0.0001]. Longitudinal Anti-S responses were greater in those with a positive T-spot [p< 0.05] or previous natural COVID-19 infection [p< 0.001] and positively correlated with serum IgM [r=0.39-0.44, p< 0.0001]. In comparison, positive T-cell IGRA responses to S-antigen were observed in 62%, 56% and 70% of patients following doses 2-4, respectively. IGRA responses were stronger in patients who had received a mix of recombinant protein and mRNA-based vaccines (compared to mRNA-based alone) [p< 0.01] and positively correlated with lymphocyte count after four doses [r=0.35, p=0.0014]. Both poor myeloma disease status (as defined by International Myeloma Working Group response group) and concurrent anti-CD38/BCMA therapy predicted lower Anti-S and IGRA responses. **Conclusions:** In summary, our data support a robust humoral and cellular immune response to COVID-19 booster doses, including in those with an initial poor response. Our data establish the laboratory and clinical profile of poor vaccine responders, that could be targeted for more intensive COVID-19 risk management, and provide insights to interrogate the biological basis of variable immunity in MM.

Introduction: Multiple myeloma (MM) typically affects the elderly, with a median age at diagnosis of 69 years. In healthy individuals, aging negatively affects the functional fitness of immune effector cells. However, the impact of aging on the immune system in MM patients remains largely unclear. We therefore profiled the phenotype of T and NK cells related to age and frailty status. Within the older patients, we then sought for the existence of patients with a younger immune profile, and evaluated whether this impacted survival. **Methods:** 261 newly diagnosed MM patients were included among which younger (range 34-65 years) and older (range 66-92 years) patients retrieved from the HO131 (EudraCT: 2014-004781-

15) and HO143 (EudraCT: 2016-002600-90) trials, respectively. Older patients were further classified as intermediate fit or frail according to the IMWG frailty score. Comprehensive immune-profiling of T and NK cells was performed by flow cytometry on study-entry peripheral blood (PB) and bone marrow (BM) samples (n=462). Data were analyzed using FlowSOM. Additionally, a lasso penalized logistic regression model was trained using cross validation to identify older patients with younger versus older immune profiles based on T cell populations identified by FlowSOM. Survival differences of these profiles were evaluated in the HO143 trial using Kaplan Meier and cox regression analysis. **Results:** In both BM and PB, older patients displayed a distinct T cell profile compared with younger patients, while NK cell profiles were similar. Older patients showed increased frequencies of activated HLA-DR+CD4+, CD38+ CD8+ and CD25+ CD8+ T cells, regulatory CD4+ T cells (Tregs) and senescent (CD28-CD57+KLRG1+) CD8+ T cells. Additionally, we observed a higher proportion of effector memory CD8+ T cells and a lower proportion of naive and central memory CD8+ T cells in older patients. Explorative analysis of T cell populations identified by FlowSOM confirmed these findings and additionally revealed decreased naive γδ T cells and increased CD38+ Tregs in older patients. Subgroup analysis of intermediate fit and frail patients revealed higher PD1 expression on CD4+ T cells in frail than in intermediate fit patients, independent of age. Preliminary results of the logistic regression model identified 13.3% of older patients having a younger T cell profile. Notably, these patients had superior overall survival (HR 3.7; 95% CI 1.16-11.85, p = 0.027) and progression free survival (HR 2.0; 95% CI 1.09-3.84 p = 0.026) in the HO143 trial compared with their peers, which was independent of age, ISS stage and cytogenetic profile. **Conclusions:** Older MM patients had more differentiated, senescent, and activated T cells than younger patients. Importantly, we identified a subgroup of older patients having a younger T cell profile, which was associated with superior survival in the HO143 trial. These new insights may improve tailoring immunotherapies and risk stratification in older MM patients.

Mezigdomide (CC-92480) activates innate and adaptive immune populations in the bone marrow microenvironment of heavily pre-treated multiple myeloma patients

Lucia Chen[1], Michael Amatangelo[2], Oliver van Oekelen[1], Bhaskar Upadhyaya[1], Alessandro Lagana[1], Geoffrey Kelly[1], Seunghee Kim-Schulze[1], Adolfo Aleman[1], Tracy Chow[2], Antonina Kurtova[3], Anita Gandhi[3], Sarah Gooding[4], Sundar Jagannath[5], Anjan Thakurta[6], Erin Flynt[3], Udo Oppermann[7], Samir Parekh[1]

[1]Icahn School of Medicine at Mount Sinai; [2]Bristol Myers Squibb, Princeton, NJ, USA; [3]Bristol Myers Squibb, Summit, NJ, USA; [4]MRC Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, UK; [5]Mount Sinai Medical Center, New York, NY, USA; [6]Radcliffe Department of Medicine, University of Oxford, Oxford, UK; [7]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, UK

Introduction: Mezigdomide (MEZI) is a novel cereblon E3 ligase modulator (CELMoD) that induces potent degradation of aiolos and ikaros. MEZI plus dexamethasone (MEZI+DEX) has demonstrated promising clinical efficacy in triple-class refractory multiple myeloma (MM) patients (pts) with ≥3 prior lines of therapy in the phase 1/2 study, CC-92480-MM-001. We report results from high-resolution mass-cytometry immune profiling of sequentially collected bone marrow (BM) samples from MM pts before and during MEZI+DEX treatment from part 1 and 2 of this study. **Methods:** A CyTOF panel of 39 markers was used for in-depth immune-phenotyping of paired longitudinal BM aspirates from MEZI+DEX-treated MM pts at baseline and mid cycle 2 or 3 of treatment. Approximately 3.6 million cells were analyzed from 38 pts dosed with 0.8-1mg of MEZI for 14 or more days of a 28-day cycle. Detailed analyses of B, T and NK cell populations were conducted using both manual hierarchical gating and a computational R workflow. **Results:** Significant changes within the BM tumour microenvironment (TME) were seen with MEZI+DEX treatment. Compared with baseline samples, on-treatment samples showed an increase in total NK (median 10.7% vs 16.5%, p=0.034) and NKT cells (median 7.6% vs 13.8%, p < 0.001). CD4 and CD8 effector memory (CCR7-CD45RA-) T cells increased on treatment (CD4 median 58.2% vs 73.9%, p < 0.001; and CD8 median 51.2% vs 71.1% p < 0.0001) with concurrent reductions in CD4 and CD8 central memory (CCR7+CD45RA-), naïve (CCR7+CD45RA+) and TEMRA (CD45RA+CCR7-) populations. Activated populations of T and NK cells also expanded on treatment. HLADR+ CD4 and CD8 T cells both increased more than three-fold (p< 0.0001), and significant increases in HLADR+ NK cells (median: 11.7% vs 17.9%, p=0.02) and ICOS+ CD4 T cells (median: 8.6% vs 14.1%, p< 0.001) were observed. Concurrently, T and NK cells showed a considerable reduction in the proportion of cells expressing the inhibitory markers KLRG1 (CD4 median 23.8% vs 15.8%, p=0.0016; CD8 median: 52.6% vs 41.0%, p=0.0013; NK median: 19.2% vs 14.9%, p=0.043) and TIGIT (CD8 median: 25.8% vs 8.2%, p< 0.0001; NK median: 18.1% vs 5.6%, p< 0.0001). Similar immune activation was observed regardless of number of prior lines of therapy and in pts refractory to pomalidomide or daratumumab. **Conclusions:** MEZI+DEX significantly activates NK and T cells in the BM TME of heavily pre-treated triple-class refractory MM pts, suggesting an important immunomodulatory mechanism of action. Marked reduction of inhibitory markers, such as KLRG1 and TIGIT, was observed in T cells and NK cells suggesting a potential role for MEZI+DEX in addressing immune cell exhaustion and promoting transition to a cytotoxic TME phenotype. While further studies are required to interrogate the role of these activated immune populations in the clearance of MM cells, this data supports the potential of MEZI+DEX to enhance the activity of other immune redirecting therapies for the treatment of MM.

15) and HO143 (EudraCT: 2016-002600-90) trials, respectively. Older patients were further classified as intermediate fit or frail according to the IMWG frailty score. Comprehensive immune-profiling of T and NK cells was performed by flow cytometry on study-entry peripheral blood (PB) and bone marrow (BM) samples (n=462). Data were analyzed using FlowSOM. Introduction: The tumor microenvironment is considered essential to maintain tumor cell survival and growth, subclonal evolution, and stage of the disease. Interactions between tumor cells and immune cells form immunosuppressive tumor-supporting niche by regulating of immune cell responses either by reducing the antitumoral activity of immune cells, expanding of immune-suppressive cells or specific mechanisms of tumor-promoting cell polarization and activation. Therefore, revealing insights into the immune myeloma microenvironment will enhance our understanding of the pathogenesis of multiple myeloma (MM). **Methods:** Our pipeline has been designed for profiling of the complex immune landscape of the adaptive and innate immune bone marrow microenvironment during MM evolution and progression in BM samples from patients with MGUS, smoldering MM (SMM), and active MM by mass cytometry analysis (CyTOF). **Results:** Our data showed that both naïve and effector cytotoxic T cells, g/d T cells, immature and mature B cells were reduced in both premalignant and active myeloma stages. In addition, downregulation of immature T cells, naïve and effector memory T helper cells was showed in active MM, revealing profound adaptive immune-suppression in myeloma microenvironment. Profiling of the innate immune microenvironment, an increase in myeloblasts, non-canonical monocytes, erythroblasts, and platelets, and a decrease in pro-monocytes was observed in both premalignant and active MM conditions. Importantly, the transformation from MGUS to SMM was associated with alterations in central/effector memory T helper cells and/or effector cytotoxic T cells, as well as increases in monocytic and neutrophil subsets. Evaluation of myeloma B lymphopoiesis revealed a decrease in B cell progenies, immature and transitional B, and unswitched memory B cells, but an increase in switched memory B cells and plasmablasts along with PC subsets in SMM and active MM stages. In addition, modulation by immune checkpoints, including PD-1/PD-L1, TIGIT/PVR, CD137/ CD137-L, CTLA-4, BTLA and KIR expression, was indicated in innate and adaptive immune subsets of myeloma microenvironment. Corresponding analysis of immune subsets of each patient revealed stratification of MM patients with high frequencies of plasma cell subsets, plasmablasts, switched memory B cells, and myelocytes that were associated with poor clinical outcomes. **Conclusions:** In conclusion, exploring the immune tumor microenvironment revealed profound adaptive immune-suppression and extensive innate immune-infiltration in both premalignant and active MM stages. Therefore, our in-depth characterization of the immune ecosystem at various stages of MM demonstrates the utility of CyTOF technology for defining disease heterogeneity and prognosis in patients with MM. Introduction: Accessory stromal and immune cells are implicated in multiple myeloma (MM) pathogenesis, although the predictive role of peculiar tumor microenvironment (TME) cells toward specific treatments has been not fully clarified. Recent computational tools allow to infer quantitative and qualitative features of TME starting from bulk transcriptomic data, enabling associations of peculiar cellular components with patients' prognosis. The aim of this work was the development of a prognostic molecular model based on TME factors to improve risk stratification of MM patients. **Methods:** A total of 59 real-life pre-treatment BM aspirates underwent immunomagnetic separation of the CD138-negative cells to generate GEP by microarray (Clariom S). This training cohort included patients receiving induction therapy by bortezomib, cyclophosphamide and dexamethasone (VCD; n=55) or bortezomib, melphalan, prednisone (VMP; n = 4), and showing stringent complete response/complete response (responders; n=24) or stable disease/progression disease (non-responders; n=35).

Introduction: Accessory stromal and immune cells are implicated in multiple myeloma (MM) pathogenesis, although the predictive role of peculiar tumor microenvironment (TME) cells toward specific treatments has been not fully clarified. Recent computational tools allow to infer quantitative and qualitative features of TME starting from bulk transcriptomic data, enabling associations of peculiar cellular components with patients' prognosis. The aim of this work was the development of a prognostic molecular model based on TME factors to improve risk stratification of MM patients. **Methods:** A total of 59 real-life pre-treatment BM aspirates underwent immunomagnetic separation of the CD138-negative cells to generate GEP by microarray (Clariom S). This training cohort included patients receiving induction therapy by bortezomib, cyclophosphamide and dexamethasone (VCD; n=55) or bortezomib, melphalan, prednisone (VMP; n = 4), and showing stringent complete response/complete response (responders; n=24) or stable disease/progression disease (non-responders; n=35).

Molecular information, including cytogenetic alterations (i.e., t(4;14), t(14;16), t(14;20), amp(1q), and del(17p)) and clinical stage (R- ISS) were available for each case. We applied the CIBERSORTx to the CD138-deriving GEP to digitally purify specific stromal and immune cell types as well as their transcriptional profiles. Thus, we identified differentially expressed genes (DEGs) comparing GEP of each purified TME cytotype between the responders and non-responders subgroup, and applying a fine-tuned statistical filtering to obtain a final gene signature. This signature was finally used to build a PFS-based predictor by a penalized Cox regression. **Results:** Our approach led to the identification of 16 genes selected by a penalized Cox model, which also provided a prognostic expression threshold capable of stratifying cases into high- and low-risk groups. These 16 genes were related to monocytes/macrophages, CD8 T cells, dendritic, natural killer and stromal cells. According to the model, 43 patients (73%) were classified as at high risk and 16 (27%) at low risk. Interestingly, the high-risk group showed a considerably worse PFS when compared with the low-risk group (log-rank P < 0.0001). Moreover, our predictor was independent from the cytogenetics risk and R-ISS in multivariate analyses. **Conclusions:** In conclusion, we demonstrated that genes reflecting TME composition hold a remarkable prognostic value in MM and may help in improving patient risk stratification independently from cytogenetic features of tumor compartment and clinical stage. Although the model was built on bortezomib-based therapy response and is under independent validation, our methodological approach appears advantageous for i) the generation of new TME-based biological hypotheses; ii) the development of future molecular tools for more accurate risk prediction in MM; and iii) potential replication of our workflow with predictive purposes toward new immunotherapies.

Introduction: The gut microbiota may impact MM development and progression. We have previously demonstrated that Prevotella heparinolytica, a human commensal, expands Th17 cells that migrate to the bone marrow (BM) were they sustain myeloma plasma cells growth. Conversely, P. melaninogenica delays MM progression by limiting Th17 expansion. Through degradation of dietary fibers, Prevotellae generate immunomodulatory short-chain fatty acids (SCFAs) which reduce Th17 differentiation. Thus, we hypothesized that the administration of a high-fiber diet, by expanding SCFA-producing bacteria, restrains Th17 expansion and prevents MM evolution. **Methods:** C57BL/6J mice challenged with Vk*MYC-derived MM cells and transgenic Vk*MYC affected by asymptomatic MM (Early-MM) were orally fed with a high-fiber diet. Gut and BM T cell infiltration and effector functions, along with effects on disease progression and overall mouse survival were taken as indicative of high-fiber diet mediated effects. To assess the impact of dietary fibers on gut microbiota composition 16S ribosomal RNA sequencing was performed on stool samples. SCFAs were quantified by NMR. **Results:** The administration of high-fiber diet in mice challenged with MM cells (t-Vk*MYC) delayed disease appearance and prolonged mice survival. Early-MM VK*MYC mice are being enrolled in a trial investigating the capacity of fiber-rich diet to delay progression to symptomatic (Late)-MM. Because high-fiber diet expands SCFA-producing Prevotellae and mice treated with P. melaninogenica produced higher levels of SCFAs than P. heparinolytica, we treated t-Vk*MYC mice with butyrate. Treatment with butyrate reduced MM aggressiveness in MM mice reducing the Th17/T regulatory cell ratio. **Conclusions:** Modulation of the gut microbiota by probiotics and postbiotics may substantially modulate the immune response thus intercepting the trajectory of MM evolution.

Introduction: Immunomodulatory agents remain the cornerstone of multiple myeloma (MM) treatment. We previously published the phase 2 trial of lenalidomide and dexamethasone (Rd) as initial therapy for MM. From this cohort, we identified a subset of long-term responders (LTRs) after Rd was discontinued. We hypothesized that improved immunosurveillance induced by the immunomodulatory actions of lenalidomide was responsible for these exceptional responses. To that end, we performed single cell transcriptomics to characterize their immune microenvironment. **Methods:** Between 2003 and 2011, 305 patients (pts) with newly diagnosed MM were treated with Rd induction. After exclusion of pts who were treated with stem cell transplantation or discontinued Rd for progression, there were 31 pts who discontinued Rd for reasons other than progression and were observed without treatment. These LTRs were defined as pts who were treated with Rd, with time to progression of 72 months or longer. Age matched controls were pts who received Rd induction but progressed within 72 months of Rd treatment. Single cell RNA sequencing was performed on CD138- sorted bone marrow (BM) at baseline and after 6 to 12 months of Rd. Gene set enrichment analyses using the reactome pathway were utilized to annotate differentially regulated biological processes using WebGestalt (http://www.webgestalt.org/). **Results:** 12 BM samples were available from 10 LTR pts and 12 control pts at baseline and after induction. BM cells were clustered based on gene expression profile and annotated to various cellular lineages using canonical marker genes. The median age at diagnosis among the LTRs was 61.5 years and controls was 53.8 years. The median duration of Rd treatment among LTRs was 72 months (range 5-125)

Molecular information, including cytogenetic alterations (i.e., t(4;14), t(14;16), t(14;20), amp(1q), and del(17p)) and clinical stage (R- ISS) were available for each case. Introduction: Immunomodulatory agents remain the cornerstone of multiple myeloma (MM) treatment. We previously published the phase 2 trial of lenalidomide and dexamethasone (Rd) as initial therapy for MM. From this cohort, we identified a subset of long-term responders (LTRs) after Rd was discontinued. We hypothesized that improved immunosurveillance induced by the immunomodulatory actions of lenalidomide was responsible for these exceptional responses. To that end, we performed single cell transcriptomics to characterize their immune microenvironment. **Methods:** Between 2003 and 2011, 305 patients (pts) with newly diagnosed MM were treated with Rd induction. After exclusion of pts who were treated with stem cell transplantation or discontinued Rd for progression, there were 31 pts who discontinued Rd for reasons other than progression and were observed without treatment. These LTRs were defined as pts who were treated with Rd, with time to progression of 72 months or longer. Age matched controls were pts who received Rd induction but progressed within 72 months of Rd treatment. Single cell RNA sequencing was performed on CD138- sorted bone marrow (BM) at baseline and after 6 to 12 months of Rd. Gene set enrichment analyses using the reactome pathway were utilized to annotate differentially regulated biological processes using WebGestalt (http://www.webgestalt.org/). **Results:** 12 BM samples were available from 10 LTR pts and 12 control pts at baseline and after induction. BM cells were clustered based on gene expression profile and annotated to various cellular lineages using canonical marker genes. The median age at diagnosis among the LTRs was 61.5 years and controls was 53.8 years. The median duration of Rd treatment among LTRs was 72 months (range 5-125)

and 9 months (range 3-34) in controls. Within the memory CD4 T cell compartment there was significant enrichment of ribosomal proteins (RPs) (RPL10,12,13,18,27,29) among the LTRs compared to the controls at diagnosis and after treatment. RPs are required for effective mTOR-mediated, metabolic reprogramming of naïve to effector T cells. PPARγ which is implicated in mTOR mediated metabolic reprogramming of CD4 T cells, was upregulated in the memory CD4 T cell compartment in LTRs. **Conclusions:** We demonstrate high expression of ribosomal proteins in the memory T cell CD4 compartment of LTRs at diagnosis and after treatment with Rd. Our study is limited by small numbers. However, our results show that the BM microenvironment in LTRs after lenalidomide therapy is characterized by a CD4 memory T cell pool with higher capacity for proliferation and differentiation. Our future goal is to compare the transcriptomic landscape of malignant cells between LTR and controls.

Introduction: The interplay between clonal plasma cells and the bone marrow (BM) microenvironment plays a crucial role in the development of multiple myeloma (MM). Therefore, understanding this relationship is crucial for identifying and effectively managing patients at a high risk of neoplastic progression, ultimately improving clinical outcomes. γδ T cells, functioning as a link between innate and adaptive immune systems, contribute to immune responses during cancer progression. However, their role in MM and its early phases, such as monoclonal gammopathy of undetermined significance (MGUS) or smoldering MM (SMM), remains unclear. Thus, this study aimed to determine the role of γδ T cells in the immunopathogenesis of MM and its preneoplastic stages. **Methods:** We conducted scRNAseq analysis on BM CD3+ cells from 3 healthy donors (HD), 5 MGUS/SMM patients, and 9 MM patients, analyzing a total of 12527 γδ T cells. Next, we performed flow cytometric analysis on 11 HD, 13 MGUS, and 29 MM patients to assess their frequency, differentiation/exhaustion profile, and effector functions. Finally, we functionally validated our results in vitro by co-culturing PBMCs or sorted γδ T cells from HD with MM cell lines. **Results:** Through scRNAseq analysis, we identified 7 γδ T cell clusters: 2 naive subpopulations (CD4-/CD8- and CD4+), 3 GZMB effector/terminally differentiated subpopulations (CD8+/TIGIT+/LAG3+, TIM3+/CD27- and GNLY+/FTH1+) and 2 GZMK memory subpopulations (GZMK+ and CXCR3+). Moreover, as MM progressed, we observed a decrease in naive γδ T cells ($p< 0.05$) followed by an increase in TIM3 expression. No significant differences were observed in the frequencies of circulating and BM Vδ1+ and Vδ2+ T cells. However, effector memory Vδ2+ cells increased in MM patients compared to preneoplastic conditions and HD, where naive and central memory populations predominated ($p< 0.05$). Co-culture with the cell line U266 confirmed the expansion in effector memory Vδ2+ T cells ($p< 0.01$) and a decrease in central memory phenotype ($p< 0.001$), indicating an MM-dependent induced phenotypic alteration. Additionally, circulating and BM Vδ2+ T cells acquired an exhausted phenotype as MM progressed, mainly demonstrated by the co-expression of TIM3 and PD1 ($p< 0.05$). This altered phenotype was associated with impaired functions of Vδ1+ and Vδ2+ T cell subsets, as evidenced by reduced TNF-α and IFN-γ expression upon in vitro stimulation, along with overexpression of the CD69 molecule ($p< 0.05$). Notably, lower percentages of circulating and BM PD1+ Vδ2+, as well as BM effector memory Vδ2+ T cells (MGUS/SMM-like profile) were associated with improved patients' 1-year progression-free survival ($p< 0.05$). **Conclusions:** BM γδ T cells acquire a dysfunctional phenotype during MM progression, which significantly impacts patient prognosis. Accordingly, circulating γδ T cells, which mimic the BM milieu, may serve as a potentially less invasive means for follow-up and prognostication of patients affected by monoclonal gammopathies.

Introduction: Multiple myeloma (MM) is the second most common incurable hematologic malignancy, characterized by the accumulation of clonal plasma cells in the bone marrow (BM). MM is preceded by two premalignant conditions, monoclonal

and 9 months (range 3-34) in controls. Within the memory CD4 T cell compartment there was significant enrichment of ribosomal proteins (RPs) (RPL10,12,13,18,27,29) among the LTRs compared to the controls at diagnosis and after treatment. RPs are required for effective mTOR-mediated, metabolic reprogramming of naïve to effector T cells. PPARγ which is implicated in mTOR mediated metabolic reprogramming of CD4 T cells, was upregulated in the memory CD4 T cell compartment in LTRs. **Conclusions:** We demonstrate high expression of ribosomal proteins in the memory T cell CD4 compartment of LTRs at diagnosis and after treatment with Rd. Our study is limited by small numbers. However, our results show that the BM microenvironment in LTRs after lenalidomide therapy is characterized by a CD4 memory T cell pool with higher capacity for proliferation and differentiation. Our future goal is to compare the transcriptomic landscape of malignant cells between LTR and controls.

Introduction: The interplay between clonal plasma cells and the bone marrow (BM) microenvironment plays a crucial role in the development of multiple myeloma (MM). Therefore, understanding this relationship is crucial for identifying and effectively managing patients at a high risk of neoplastic progression, ultimately improving clinical outcomes. γδ T cells, functioning as a link between innate and adaptive immune systems, contribute to immune responses during cancer progression. However, their role in MM and its early phases, such as monoclonal gammopathy of undetermined significance (MGUS) or smoldering MM (SMM), remains unclear. Thus, this study aimed to determine the role of γδ T cells in the immunopathogenesis of MM and its preneoplastic stages. **Methods:** We conducted scRNAseq analysis on BM CD3+ cells from 3 healthy donors (HD), 5 MGUS/SMM patients, and 9 MM patients, analyzing a total of 12527 γδ T cells. Next, we performed flow cytometric analysis on 11 HD, 13 MGUS, and 29 MM patients to assess their frequency, differentiation/exhaustion profile, and effector functions. Finally, we functionally validated our results in vitro by co-culturing PBMCs or sorted γδ T cells from HD with MM cell lines. **Results:** Through scRNAseq analysis, we identified 7 γδ T cell clusters: 2 naive subpopulations (CD4-/CD8- and CD4+), 3 GZMB effector/terminally differentiated subpopulations (CD8+/TIGIT+/LAG3+, TIM3+/CD27- and GNLY+/FTH1+) and 2 GZMK memory subpopulations (GZMK+ and CXCR3+). Moreover, as MM progressed, we observed a decrease in naive γδ T cells ($p< 0.05$) followed by an increase in TIM3 expression. No significant differences were observed in the frequencies of circulating and BM Vδ1+ and Vδ2+ T cells. However, effector memory Vδ2+ cells increased in MM patients compared to preneoplastic conditions and HD, where naive and central memory populations predominated ($p< 0.05$). Co-culture with the cell line U266 confirmed the expansion in effector memory Vδ2+ T cells ($p< 0.01$) and a decrease in central memory phenotype ($p< 0.001$), indicating an MM-dependent induced phenotypic alteration. Introduction: Multiple myeloma (MM) is the second most common incurable hematologic malignancy, characterized by the accumulation of clonal plasma cells in the bone marrow (BM). MM is preceded by two premalignant conditions, monoclonal

gammopathy of undetermined significance (MGUS) and smoldering MM (SMM), with respective evolution rates of 1% and 10% per year. Understanding the factors that drive neoplastic transformation and managing high-risk patients are critical for improving clinical outcomes and implementing early therapeutic interventions. Because the genomic landscape often overlaps between premalignant conditions and active MM, the latest research has focused on the role of the BM immune microenvironment. This study aims to characterize BM immune changes during MGUS-MM progression and their association with outcome in MM patients. **Methods:** We used FlowCT, a semi-automated pipeline for flow cytometry data analysis, to compare the immune composition in the BM of 12 MGUS, 12 SMM, and 63 MM patients stained with two common 8-markers diagnostic tubes. Next, we performed Luminex assays for the simultaneous quantification of 48 cytokines and chemokines using plasma samples of BM and peripheral blood (HD=4, MGUS=12, SMM=12, and MM=12) to obtain a MM immune response profiling. **Results:** Progression to clinical MM was associated with a decrease in granulocytes (mean, 74.18% MGUS vs 73.86% SMM vs 65.59% MM; p< 0.05) and an increase in monocytes (mean, 4.97% MGUS vs 4.62% SMM vs 6.77% MM; p< 0.01), T lymphocytes (mean, 6.29% MGUS vs 7.56% SMM vs 11% MM; p< 0.01), and NK cells (mean, 0.88% MGUS vs 1.51% SMM vs 2.13% MM; p< 0.001). Effector CD38+CD81+CD28- NK/T lymphocytes were abundant in MM patients (mean, 2.50% MGUS vs 2.28% SMM vs 4.31% MM; p< 0.05) and CD27- vs CD27+ NK/T lymphocytes ratio augmented during disease progression (p< 0.05). Interestingly, we observed a concomitant reduction of GM-CSF, IFN-α2, IFN-γ, IL-1β, IL-2, IL-2Ra, IL-3, IL-10, IL-13, and MCP-1/CCL2 levels within the BM plasma along MM evolution which could contribute to the myeloid cell decline occurring in these patients. Moreover, PDGF-BB, IFN-α2, IL-16, and IL-8 decrease could be even observed in peripheral blood plasma along MM progression. From a clinical point of view, we evaluated the impact of previously disclosed BM changes on progression-free survival (PFS) of 50 patients with active MM and found that the abundance of granulocytes was associated with a longer PFS (HR: 0.15; p< 0.05). Furthermore, patients treated with daratumumab who had a high BM neutrophil/T lymphocyte ratio showed a substantially longer 1-year PFS (HR: 0.07; p< 0.01) than those who had a low ratio (86% vs 33%, respectively). **Conclusions:** Overall, our findings suggest that immune factors play a crucial role in disease development and response to therapy, emphasizing the importance of immune-based approaches for improving patient outcomes in MM.

Introduction: The multiple myeloma (MM) bone marrow (BM) is characterized by IL-6 producing tumor-supportive inflammatory mesenchymal stromal cells (iMSC). iMSC are a source of neutrophil-modulation factors including IL6, C3 and chemokines for neutrophil-expressed CXCR1 and CXCR2. Since the BM permanently harbors large numbers of neutrophils, we hypothesized that stromal–neutrophil interactions might significantly impact the tumor-supportive BM environment in MM. **Methods:** To investigate BM neutrophils in MM, we generated a single-cell transcriptomic overview of the entire neutrophilic lineage from fresh BM aspirates of 6 newly diagnosed MM (NDMM) patients, 6 MM patients that had completed intensive first-line treatment and four age-matched controls. In addition, single-cell RNA libraries were generated from BM MSC of 5 MM patients after intensive treatment. Functional interrogation of neutrophils and stromal cells included ex-vivo co-cultures, flow cytometric analyses, and RNA sequencing. **Results:** Single-cell RNA-sequencing of the BM neutrophilic lineage in newly-diagnosed MM identified an increase in the percentage of mature neutrophils, and these cells were defined by inflammatory gene programs and genes associated with activation (DUSP1, GBP5), adhesion (ITGAX, ITGAL), and inflammation (OSM, CXCL8). Mature neutrophils in MM BM had an MM-supportive phenotype with increased transcription of the BCMA-ligand BAFF and the pro-inflammatory cytokine IL1B. In vitro co-cultures revealed that iMSC were sufficient to induce the MM neutrophil phenotype, including pro-inflammatory gene modules and production of BAFF and IL-1β. Neutrophil activation by iMSC was STAT3 dependent and could be abrogated by the STAT3-inhibitor Stattic. Reciprocally, iMSC-activated neutrophils gained the ability to induce MM-supportive iMSCs from non-activated stromal cells in an IL-1B-dependent manner. These data suggest that stromal cell-driven neutrophil activation could be involved in amplifying pro-tumor BM inflammation. To test whether this tumor-supportive inflammatory axis persists after first-line treatment, we performed single-cell RNA sequencing of neutrophils and MSC of patients that had completed induction- and consolidation therapy with triplet +/- anti-CD38 therapy, including high-dose melphalan and autologous stem cell transplant. iMSC were significantly reduced post-consolidation, but percentages remained elevated compared to controls. BM neutrophils, which were newly-formed post-transplant, had been re-activated and had re-acquired a pro-tumor phenotype. This was reflected in significantly elevated protein levels of BAFF and IL-1β in BM plasma of 52 patients after first-line treatment compared to non-cancer controls. **Conclusions:** We identified an MM-supportive BM environment driven by MSC-neutrophil interactions that persist after treatment. Our data warrant investigation into novel strategies targeting both stromal and immune activation to disrupt the tumor-supportive BM environment in MM.

gammopathy of undetermined significance (MGUS) and smoldering MM (SMM), with respective evolution rates of 1% and 10% per year. Understanding the factors that drive neoplastic transformation and managing high-risk patients are critical for improving clinical outcomes and implementing early therapeutic interventions. Because the genomic landscape often overlaps between premalignant conditions and active MM, the latest research has focused on the role of the BM immune microenvironment. This study aims to characterize BM immune changes during MGUS-MM progression and their association with outcome in MM patients. **Methods:** We used FlowCT, a semi-automated pipeline for flow cytometry data analysis, to compare the immune composition in the BM of 12 MGUS, 12 SMM, and 63 MM patients stained with two common 8-markers diagnostic tubes. Next, we performed Luminex assays for the simultaneous quantification of 48 cytokines and chemokines using plasma samples of BM and peripheral blood (HD=4, MGUS=12, SMM=12, and MM=12) to obtain a MM immune response profiling. **Results:** Progression to clinical MM was associated with a decrease in granulocytes (mean, 74.18% MGUS vs 73.86% SMM vs 65.59% MM; p< 0.05) and an increase in monocytes (mean, 4.97% MGUS vs 4.62% SMM vs 6.77% MM; p< 0.01), T lymphocytes (mean, 6.29% MGUS vs 7.56% SMM vs 11% MM; p< 0.01), and NK cells (mean, 0.88% MGUS vs 1.51% SMM vs 2.13% MM; p< 0.001). Effector CD38+CD81+CD28- NK/T lymphocytes were abundant in MM patients (mean, 2.50% MGUS vs 2.28% SMM vs 4.31% MM; p< 0.05) and CD27- vs CD27+ NK/T lymphocytes ratio augmented during disease progression (p< 0.05). Interestingly, we observed a concomitant reduction of GM-CSF, IFN-α2, IFN-γ, IL-1β, IL-2, IL-2Ra, IL-3, IL-10, IL-13, and MCP-1/CCL2 levels within the BM plasma along MM evolution which could contribute to the myeloid cell decline occurring in these patients. Introduction: Multiple Myeloma (MM) is associated with skewed immune cell activation and function. Univariate analyses show individual immune cells are altered in precursor states. However, a comprehensive model linking immune processes during progression and their interaction with tumour cells is lacking. **Methods:** We generated a large dataset of published and newly-generated bone marrow single-cell RNA sequencing (scRNAseq): >914,000 cells from patients with MM MM (n=46), the precursor conditions MGUS (n=19) and SMM (n=28) and non-cancer controls (n=58). scvi was used integration, and both regression and unsupervised approaches for differential abundance. Tumour cells were identified via their unique combination of immunoglobulin genes. **Results:** We characterise two immune profiles (immunotypes), composed of immune cells which co-associate in abundance. The first immunotype reflected aging-like differentiation including a loss of naive T cells, B cells, and haematopoietic progenitors; and an enrichment of differentiated T cells, NK cells and activated dendritic cells (DCs). This immunotype correlated with age in controls (R=-0.68, P< 0.001), reflecting healthy aging. This immunotype was enriched in MM patients independent of age (P=0.004), rising with advancing severity (MGUS to SMM to MM), such that patients had increasingly prematurely-aged immune composition. This immunotype correlated with tumour MHC class I (MHC-I) expression (R=0.43, P = 0.007), which fell between SMM to MM (HLA-C, P=0.029), meaning patients whose tumours expressed the lowest MHC-I were the most immunosenescent. Within this immunotype, a clonal effector memory CD8+ T cells expressing a genes enriched in non-viral clones (GZMB+ITGB1+) correlated with tumour MHC-I (R=0.33, P=0.002). The second immunotype was composed of inflammatory cell types, including Interferon Stimulated Gene (ISG)-expressing T and B cells, inflammatory CD4+ regulatory T cells and plasmacytoid DCs. This immunotype was enriched in osteoarthritic non-cancer controls alongside MM (but not MGUS or SMM) patients. This immunotype was most pronounced in highly-infiltrated marrows (aspirate CD138+ %) and those with the greatest proportion of proliferating tumour cells (% MKI67+ tumour), suggesting tumour growth-associated inflammatory niche remodelling. ISG+ effector T cells enriched in infiltrated marrows shared T cell receptors with cytotoxic terminal memory T cells accumulating within the aging-like immunotype, suggesting a link between these two immunotype processes. **Conclusions:** We unify the variation in bone marrow immune architecture in the progression to Myeloma into two key processes (immunotypes). Age-independent, tumour MHC-I-dependent immunosenescent-like differentiation could indicate an accumulation of historical anti-tumour responses leading up to progression. Osteoarthritic-like inflammatory cells enriched in MM reflecting local tumour burden and growth may possibly represent acute anti-tumour responses occurring in situ.

Introduction: The benefit of high-dose therapy and autologous stem cell transplantation (ASCT) comes largely from tumour reduction, enhancing depth of response. The degree to which ASCT amplifies host anti-tumour immunity is not fully understood. Immune reconstitution following ASCT manifest as the accumulation of differentiated T cell subsets, and studies in mice indicate this represents an expansion of tumour-specific CD8+ T cell clones. We compared T cell phenotypes and repertoires between patients receiving ASCT and those receiving chemotherapy only, to understand the specific role of ASCT in T cell responses. **Methods:** We utilised BM samples from patients in the Cardamon (ClinicalTrials.gov NCT02315716) Phase 2 study, where patients

Introduction: Multiple Myeloma (MM) is associated with skewed immune cell activation and function. Univariate analyses show individual immune cells are altered in precursor states. However, a comprehensive model linking immune processes during progression and their interaction with tumour cells is lacking. **Methods:** We generated a large dataset of published and newly-generated bone marrow single-cell RNA sequencing (scRNAseq): >914,000 cells from patients with MM MM (n=46), the precursor conditions MGUS (n=19) and SMM (n=28) and non-cancer controls (n=58). scvi was used integration, and both regression and unsupervised approaches for differential abundance. Tumour cells were identified via their unique combination of immunoglobulin genes. **Results:** We characterise two immune profiles (immunotypes), composed of immune cells which co-associate in abundance. The first immunotype reflected aging-like differentiation including a loss of naive T cells, B cells, and haematopoietic progenitors; and an enrichment of differentiated T cells, NK cells and activated dendritic cells (DCs). This immunotype correlated with age in controls (R=-0.68, P< 0.001), reflecting healthy aging. This immunotype was enriched in MM patients independent of age (P=0.004), rising with advancing severity (MGUS to SMM to MM), such that patients had increasingly prematurely-aged immune composition. This immunotype correlated with tumour MHC class I (MHC-I) expression (R=0.43, P = 0.007), which fell between SMM to MM (HLA-C, P=0.029), meaning patients whose tumours expressed the lowest MHC-I were the most immunosenescent. Within this immunotype, a clonal effector memory CD8+ T cells expressing a genes enriched in non-viral clones (GZMB+ITGB1+) correlated with tumour MHC-I (R=0.33, P=0.002). The second immunotype was composed of inflammatory cell types, including Interferon Stimulated Gene (ISG)-expressing T and B cells, inflammatory CD4+ regulatory T cells and plasmacytoid DCs. This immunotype was enriched in osteoarthritic non-cancer controls alongside MM (but not MGUS or SMM) patients. This immunotype was most pronounced in highly-infiltrated marrows (aspirate CD138+ %) and those with the greatest proportion of proliferating tumour cells (% MKI67+ tumour), suggesting tumour growth-associated inflammatory niche remodelling. ISG+ effector T cells enriched in infiltrated marrows shared T cell receptors with cytotoxic terminal memory T cells accumulating within the aging-like immunotype, suggesting a link between these two immunotype processes. **Conclusions:** We unify the variation in bone marrow immune architecture in the progression to Myeloma into two key processes (immunotypes). Age-independent, tumour MHC-I-dependent immunosenescent-like differentiation could indicate an accumulation of historical anti-tumour responses leading up to progression. Osteoarthritic-like inflammatory cells enriched in MM reflecting local tumour burden and growth may possibly represent acute anti-tumour responses occurring in situ.

Introduction: The benefit of high-dose therapy and autologous stem cell transplantation (ASCT) comes largely from tumour reduction, enhancing depth of response. The degree to which ASCT amplifies host anti-tumour immunity is not fully understood. Immune reconstitution following ASCT manifest as the accumulation of differentiated T cell subsets, and studies in mice indicate this represents an expansion of tumour-specific CD8+ T cell clones. We compared T cell phenotypes and repertoires between patients receiving ASCT and those receiving chemotherapy only, to understand the specific role of ASCT in T cell responses. **Methods:** We utilised BM samples from patients in the Cardamon (ClinicalTrials.gov NCT02315716) Phase 2 study, where patients

received carfilzomib, cyclophosphamide and dexamethasone (KCd) induction followed by randomisation to ASCT or KCd consolidation (cons). For both arms, samples were acquired at baseline, and post-ASCT or post-cons. Viably frozen cells were thawed and used as input for flow cytometry, T cell receptor (TCR) sequencing (TCRseq), and 10x Genomics single-cell RNA and TCR sequencing (scRNA/TCR-seq). **Results:** Flow cytometry showed an enrichment of CD8+ terminal effector memory cells (CCR7-PD1-CD57+GZMB+) post-ASCT (n=10) compared to post-cons (n=10). On longitudinal bulk TCRseq, post-ASCT (n=14) displayed greater TCR clonality than post-cons (n=15), in part due to the expansion of pre-existing TCRs present at baseline (some expanding >10,000-fold). Within each patient, expanding TCRs possessed similar structural sequences suggesting shared antigen specificity, but were not enriched for clones annotated to HLA-matched virally-annotated TCRs. scRNA/TCR-seq of post-ASCT patients (n=4) connected the TCRs which expanded post-ASCT to a similar memory phenotype (CD8A+GZMB+CX3CR1+). Analysis of baseline (n=2) and longitudinal (n=1) ASCT patients showed the clones which subsequently expanded post-ASCT occupied this same memory phenotype at baseline, albeit at lower numbers. These clones exhibited a wider range of states post-ASCT, including early activated (GZMK+PDCD1+) and proliferating (MKI67+) clusters, but did not progress unidirectionally into a more terminally differentiated phenotype. This suggests ASCT elicits a phenotypic diversification rather than induction of terminal differentiation. Some clones which expanded post-ASCT were actively proliferating, suggesting an ongoing source of stimulation. Patients with the highest clonality and most proliferating KI67+CD8+ T cells by flow cytometry post-treatment were minimal residual disease (MRD) positive, suggesting ongoing anti-tumour responses. **Conclusions:** Our results provide of evidence of antigen-driven T cell expansion following ASCT that was not seen after chemotherapy consolidation. A small number of TCR clones present at baseline undergo phenotypic diversification and proliferate, expanding to occupy a large portion of the T cell compartment and may inform on or protect against residual tumour cells.

Introduction: Multiple myeloma cells activate osteoclasts by producing osteoclastogenic factors. Our previous work demonstrated that matrix metalloproteinase 13 (MMP-13) is one of the critical osteoclastogenic factors highly secreted by MM cells (JCI 2016). Further studies indicated that checkpoint inhibitor PD-1H/VISTA functions as the MMP-13 receptor on osteoclasts and mediates the MMP-13-induced osteoclast activation. Interestingly, PD-1H pulldown mass spectrum assay suggests that PD-1H associates with cytoskeleton proteins. Further, we found PD-1H regulates the F-actin cytoskeleton reorganization which is critical for osteoclast bone resorption activity. Since Rho GTPases substrates Rac1/2 are the key regulators of the dynamic actin cytoskeleton rearrangements, we investigated its role in PD-1H mediated OCL formation/activation. **Methods:** Bone marrow mononuclear cells from WT or Pd-1h-/- mice were cultured in osteoclast differentiation medium without or with MMP-13. Activated Rac1 was detected in Rac1 pull-down complex from whole cell lysates by WB. Localization of c-Src, Rac1, PD-1H and F-actin ring in osteoclast were detected by confocal immunofluorescence (IF) microscope and activation of c-Src was detected by western blotting. The binding of c-Src with PD-1H and 1-215 mutant was checked by co-IP assay after co-expressed in HEK 293 cells. **Results:** Our results showed that MMP-13 activated Rac1 in WT, but not Pd-1h-/- osteoclasts. IF staining indicated that PD-1H and Rac1 co-localized, especially at the F-actin belt in WT osteoclasts. Consistent with the decreased Rac1 activation and F-actin belt formation observed in Pd-1h-/- osteoclasts, Rac1 failed to localize at F-actin-rich areas in Pd-1h knockout cells. Non-receptor tyrosine kinase c-Src associates with RANK and mediates RANKL-induced Rac1 activation and cytoskeleton reorganization. Confocal IF staining of the WT osteoclasts indicated that c-Src and PD-1H almost completely co-localized on the F-actin sealing belt and perinuclear area. Co-immunoprecipitation assays confirmed the direct binding of c-Src to the C-terminal intracellular domain of PD-1H as a PD-1H 1-215 mutant lacking its intracellular domain failed to bind c-Src. IF staining of c-Src, PD-1H and F-actin indicated that in contrast to WT osteoclasts, c-Src in Pd-1h-/- osteoclasts mainly accumulated in perinuclear areas, but not in the F-actin belt hereby not allowing appropriate cytoskeleton reorganization necessary for OCL formation. Finally, MMP-13 induced c-Src phosphorylation/activation in WT osteoclasts, which was impaired in Pd-1h-/- cells. **Conclusions:** This study reveals the novel role of MMP-13/PD-1H signaling in the regulation of osteoclasts cytoskeleton reorganization. MMP-13 binds to PD-1H and promotes c-Src/Rac1 signaling activation and subsequently promotes osteoclast bone resorption activities. This study hence revealed a novel role of the checkpoint inhibitor PD-1H/VISTA in osteoclast cytoskeleton regulation and subsequently multiple myeloma bone disease.

Introduction: Daratumumab (Dara) has become a mainstay in treatment-naïve and relapsed/refractory Multiple Myeloma patients (RRMM). While Dara is expected to bind myeloma cells, it also impacts the immune microenvironment by targeting CD38+ immune suppressor and effector cells. The clinical consequence of this redirected CD38-targeted activity is worth of investigation to understand the mechanisms of relapse and maximize the efficacy and duration of Dara treatment. **Methods:** We investigated the immune modulation induced by Dara in 32 RRMM enrolled in the NCT03848676 clinical study (Dara-Len-Dex) through extensive multiparametric flowcytometry phenotyping and quantification performed on bone marrow (BM) and peripheral blood (PB) mononuclear cells. For each patient BM and PB were profiled at baseline, with good concordance between the two compartments (linear regression slope=0.63, p< 0.001, r2=0.27). Longitudinal PB samples were collected every 3 months for a total of 170 samples profiled. **Results:** In all patients irrespective of the clinical response, we observed a long-lasting CD38 down-regulation in PB NK cells, T cells, Vγ9Vδ2 T cells, regulatory T cells (Tregs), and regulatory B cells (Bregs). On the contrary, PB Monocytes and Myeloid-derived suppressor cells (MDSC) showed CD38 variable and not persistent down-regulation pattern. In NK cells, CD38 decrease was associated with CD16 (FcγRIII) down-modulation and NK-cell subset re-distribution. Dara-Len-Dex also induced the persistent decrease of PB CD38+Tregs and CD38+Bregs and the increase of functionally exhausted T cells. A comparison between relapsed (R) (n=12) and non-relapsed (NR) (n=19) patients indicates that clinical outcomes were associated with specific baseline patterns of CD38 expression, BM Bregs abundance, PB T-cell and monocyte subpopulation redistribution, and expression of exhaustion T-cell markers. Low CD38 mean fluorescence intensity in myeloma cells and high CD38 expression in BM NK cells (p=0.03) were strongly associated with early progression (< 1 year). This pattern suggested that in R patients Dara was likely preferentially redirected towards NK cells rather than myeloma cells promoting more NK fratricide than antibody-dependent cellular cytotoxicity against myeloma cells. High CD38 expression in BM MDSC of R patients at baseline further reduce Dara-mediated myeloma cell targeting. T-cell and granulocytic-MDSC (Gn-MDSC) total counts were differently modulated by Dara-based treatment over time according to clinical outcomes. T cells increased from 9 months of therapy in NR but not in R patients (p=0.007). Likewise, Gn-MDSC were not affected in NR patients while increased in R patients from 9 months (p=0.009). **Conclusions:** Our data indicate that Dara-based treatment induces long-lasting changes in the immune populations involved in the disease control and unveil an association between CD38+ expression in selected immune cell subsets at baseline, Dara treatment, and response to treatment.

Introduction: Patients with multiple myeloma (MM) are immunocompromised due to impaired humoral and cellular immunity in addition to immunosuppressive therapy. The situation and protective effects of severe coronavirus disease 2019 (COVID-19) vaccination in MM patients are not clarified. The study aimed to explore the reasons of COVID-19 vaccine hesitancy and its influence on severe acute respiratory syndrome coronavirus 2 (SARS-COV-2) infection in MM patients during COVID-19 Omicron BA.4/5 subvariant outbreak in China. **Methods:** An anonymous online questionnaire designed by our team was distributed to MM patients national-wide from December 26, 2022, to April 20, 2023. Then content of questionnaire included the contents of disease status, vaccination and SARS-COV-2 infection. **Results:** A total of 508 valid questionnaires from 30 provinces were collected all over China. The vaccination rate of COVID-19 in MM patients was only 34.1% (n=173). The overall infection rate was 57.2%. Multivariate analysis showed that demographic characteristics were not factors affecting vaccination, while those accomplishing autologous stem cell transplantation (ASCT) presented a lower vaccination rate (20.2% vs. 48.4%, P< 0.001). In the survey of vaccine acceptance/hesitancy, voluntary choice (49%), concerns to COVID-19 infection (35.1%), and trust of vaccine efficacy (26.5%) were the three main reasons for receiving vaccines. Physicians' suggestion (52.0%), conflicts of MM treatment (37.8%) and concerns about MM progression (31.3%) were the top three reasons for vaccine hesitancy. Adverse events (AEs) after vaccination were mainly myalgia or joint pain, fatigue and erythema or swelling at the site of injection. No MM disease-related adverse effects were reported. Among 104 vaccinated MM patients with SARS-COV-2 infection, the median time since last vaccines to infections was 304 days (range 4-593). The infection rates between

Introduction: Daratumumab (Dara) has become a mainstay in treatment-naïve and relapsed/refractory Multiple Myeloma patients (RRMM). While Dara is expected to bind myeloma cells, it also impacts the immune microenvironment by targeting CD38+ immune suppressor and effector cells. The clinical consequence of this redirected CD38-targeted activity is worth of investigation to understand the mechanisms of relapse and maximize the efficacy and duration of Dara treatment. **Methods:** We investigated the immune modulation induced by Dara in 32 RRMM enrolled in the NCT03848676 clinical study (Dara-Len-Dex) through extensive multiparametric flowcytometry phenotyping and quantification performed on bone marrow (BM) and peripheral blood (PB) mononuclear cells. For each patient BM and PB were profiled at baseline, with good concordance between the two compartments (linear regression slope=0.63, p< 0.001, r2=0.27). Longitudinal PB samples were collected every 3 months for a total of 170 samples profiled. **Results:** In all patients irrespective of the clinical response, we observed a long-lasting CD38 down-regulation in PB NK cells, T cells, Vγ9Vδ2 T cells, regulatory T cells (Tregs), and regulatory B cells (Bregs). On the contrary, PB Monocytes and Myeloid-derived suppressor cells (MDSC) showed CD38 variable and not persistent down-regulation pattern. In NK cells, CD38 decrease was associated with CD16 (FcγRIII) down-modulation and NK-cell subset re-distribution. Dara-Len-Dex also induced the persistent decrease of PB CD38+Tregs and CD38+Bregs and the increase of functionally exhausted T cells. A comparison between relapsed (R) (n=12) and non-relapsed (NR) (n=19) patients indicates that clinical outcomes were associated with specific baseline patterns of CD38 expression, BM Bregs abundance, PB T-cell and monocyte subpopulation redistribution, and expression of exhaustion T-cell markers. Low CD38 mean fluorescence intensity in myeloma cells and high CD38 expression in BM NK cells (p=0.03) were strongly associated with early progression (< 1 year). This pattern suggested that in R patients Dara was likely preferentially redirected towards NK cells rather than myeloma cells promoting more NK fratricide than antibody-dependent cellular cytotoxicity against myeloma cells. High CD38 expression in BM MDSC of R patients at baseline further reduce Dara-mediated myeloma cell targeting. T-cell and granulocytic-MDSC (Gn-MDSC) total counts were differently modulated by Dara-based treatment over time according to clinical outcomes. T cells increased from 9 months of therapy in NR but not in R patients (p=0.007). Likewise, Gn-MDSC were not affected in NR patients while increased in R patients from 9 months (p=0.009). **Conclusions:** Our data indicate that Dara-based treatment induces long-lasting changes in the immune populations involved in the disease control and unveil an association between CD38+ expression in selected immune cell subsets at baseline, Dara treatment, and response to treatment.

Introduction: Patients with multiple myeloma (MM) are immunocompromised due to impaired humoral and cellular immunity in addition to immunosuppressive therapy. The situation and protective effects of severe coronavirus disease 2019 (COVID-19) vaccination in MM patients are not clarified. The study aimed to explore the reasons of COVID-19 vaccine hesitancy and its influence on severe acute respiratory syndrome coronavirus 2 (SARS-COV-2) infection in MM patients during COVID-19 Omicron BA.4/5 subvariant outbreak in China. **Methods:** An anonymous online questionnaire designed by our team was distributed to MM patients national-wide from December 26, 2022, to April 20, 2023. Then content of questionnaire included the contents of disease status, vaccination and SARS-COV-2 infection. **Results:** A total of 508 valid questionnaires from 30 provinces were collected all over China. The vaccination rate of COVID-19 in MM patients was only 34.1% (n=173). The overall infection rate was 57.2%. Multivariate analysis showed that demographic characteristics were not factors affecting vaccination, while those accomplishing autologous stem cell transplantation (ASCT) presented a lower vaccination rate (20.2% vs. 48.4%, P< 0.001). In the survey of vaccine acceptance/hesitancy, voluntary choice (49%), concerns to COVID-19 infection (35.1%), and trust of vaccine efficacy (26.5%) were the three main reasons for receiving vaccines. Physicians' suggestion (52.0%), conflicts of MM treatment (37.8%) and concerns about MM progression (31.3%) were the top three reasons for vaccine hesitancy. Adverse events (AEs) after vaccination were mainly myalgia or joint pain, fatigue and erythema or swelling at the site of injection. No MM disease-related adverse effects were reported. Among 104 vaccinated MM patients with SARS-COV-2 infection, the median time since last vaccines to infections was 304 days (range 4-593). The infection rates between

the vaccinated population (n=173) versus non-vaccinated ones (n=335) were 60.1% vs. 55.8% respectively (P=0.35). In subgroup analyses, the infection rates in vaccinated patients were lower than those in unvaccinated ones including the elderly (49.3% vs. 55.2%), obese patients (BMI≥28) (50% vs. 63.3%), and R/RMM population (42.2% vs. 66.7%, P=0.005). The proportion of hospitalized patients due to SARS-COV-2 infection in vaccinated group was significantly lower than that in unvaccinated group (4.8% vs.12.3%, P=0.038). **Conclusions:** Vaccine hesitation is common in Chinese MM patients although inactivated COVID-19 vaccine only causes mild AEs. Lower infection rate in MM patients is probably due to strict self-quarantine. COVID-19 vaccination is not translated into less SARS-COV-2 infections, but does protect the elderly, obese or R/RMM patients from severe infections. Clinicians are suggested to encourage MM patients to receive COVID-19 vaccines for the sake of reducing severe infections and related mortality.

Introduction: While the treatment of multiple myeloma (MM) has greatly improved, most patients eventually relapse. The time to relapse is variable with some patients relapsing within months and others remaining in remission for years. We hypothesize there are differences in the bone marrow (BM) microenvironment (ME) that underlie earlier progression; identification of factors associated with prolonged remission could be leveraged to benefit patients with early relapse. The BM ME is defined by specific cell types and proximity to MM cells and the rich array of plasma proteins, including those with regulatory activity impacting residual MM cell growth and survival. In this study, we analyzed BM plasma samples from MM patients with differing clinical outcome to identify plasma biomarkers that predict outcome at d100 post-autologous stem cell transplant (ASCT). **Methods:** Two different proteomic platforms were used. The SomaLogic platform is aptamer-based and measures 7000 proteins. For the SomaLogic studies, BM plasma samples were collected (2006-2019) from 104 MM patients ~d100 post-ASCT. Poor responders (PRs; n=38) were defined as relapsing 2yr if not put on MT and >4yr if placed on MT (n=66). The Olink Explore 3072 platform uses proximity extension assay technology coupled with NGS and measures 3000 proteins. For the Olink studies, BM plasma samples from an independent cohort of MM patients (40 PRs and 40 GRs) were collected at ~d100 post-ASCT (2017-2018), all of whom received MT post-ASCT. Initially, the top principal components of the most variable features were clustered via nearest neighbor routines to identify potential non-biological groupings in both sets of proteomic data. Subsequently, differential expression via limma was performed to identify the most significantly up-regulated and down-regulated features for PRs after controlling for the non-biological groupings. **Results:** Notably, an abundance of cytokines was observed in PRs at ~d100 using both platforms. In the SomaLogic data, key genes within the cytokine-cytokine receptor interactions pathway were identified among the top 50 up-regulated proteins including CXCL10, IL18, IL21R, CXCL14, and IL17RB. The Olink data also showed up-regulated proteins in the PRs were related to cytokines and included CXCL1, CXCL8, CXC11, and IRAK4. We also explored possible effects of residual plasma cells (PCs) present at ~d100 post-ASCT. After adjusting for the % of PCs present, we still observed CXCL1, CXCL8, and CXCL11 in the top 50 up-regulated proteins. **Conclusions:** Our data suggest that the BM plasma cytokine milieu in MM patients post-ASCT may indicate which patients are more likely to progress. Our data further suggest that the association between chemokines and poor prognosis is largely independent of tumor involvement and may largely reflect the BM ME instead.

Introduction: It is clinically experienced and also biologically documented that multiple myeloma (MM) is in itself a heterogeneous disorder as covers multiple different characterized clones. Currently, the treatment is not strictly individualized yet and includes still high-dose chemotherapy with melphalan in transplant-eligible patients. We focused on emerging data on gut microbiota which may be disturbed during chemotherapy and may have a role in the passage of inflammatory mediators through the intestinal barrier. We studied microbiota changes in MM patients and documented the data at diagnosis and after treatment. **Methods:** Stool samples were taken twice, before and after the 4th therapy course. The samples were sequenced using the next-generation sequencing (NGS) method after nucleic acid isolation. OTU (Operational taxonomic unit) tables were prepared using NCBI Blastn version 2.0.12 according to NCBI general 16S bacterial taxonomy reference dated 10.08.2021. The OTU tables were calculated and plotted using R Statistical Computer Language version 4.04 (readr, phyloseq, microbiome, vegan, descry, and ggplot2 packages) to calculate Alpha diversity. Statistical analyses were also performed using R Statistical Computer Language version 4.0.4 and Rstudio IDE 1.4 (tidyverse, readr, xlsx, and ggplot2 packages). The associated pathways were analyzed with the KEGG (Kyoto Encyclopedia of Genes and Genomes) database. **Results:** Fifteen newly diagnosed MM patients enrolled

the vaccinated population (n=173) versus non-vaccinated ones (n=335) were 60.1% vs. 55.8% respectively (P=0.35). In subgroup analyses, the infection rates in vaccinated patients were lower than those in unvaccinated ones including the elderly (49.3% vs. 55.2%), obese patients (BMI≥28) (50% vs. 63.3%), and R/RMM population (42.2% vs. 66.7%, P=0.005). The proportion of hospitalized patients due to SARS-COV-2 infection in vaccinated group was significantly lower than that in unvaccinated group (4.8% vs.12.3%, P=0.038). **Conclusions:** Vaccine hesitation is common in Chinese MM patients although inactivated COVID-19 vaccine only causes mild AEs. Lower infection rate in MM patients is probably due to strict self-quarantine. COVID-19 vaccination is not translated into less SARS-COV-2 infections, but does protect the elderly, obese or R/RMM patients from severe infections. Clinicians are suggested to encourage MM patients to receive COVID-19 vaccines for the sake of reducing severe infections and related mortality.

The gut microbiota changes during multiple myeloma treatment

Sevgi Kalayoglu-Besisik[1], Fatma Savran Oguz[2], Zerrin Aktas[3], Oral Oncul[4], Ekin Ece Gurer[2], Tarik Onur Tiryaki[1], Ugur Sezerman[5]

[1]Istanbul University, Istanbul Faculty of Medicine/Department of Internal Medicine, Division of Hematology; [2]Istanbul University, Istanbul Faculty of Medicine/Medical Biology; [3]Istanbul Faculty of Medicine/Department of Clinical Microbiology; [4]Istanbul Faculty of Medicine/Department of Infectious Diseases and Clinical Microbiology; [5]Acibadem University, Faculty of Medicine/ Department of Biostatistics and Medical Informatics

Introduction: It is clinically experienced and also biologically documented that multiple myeloma (MM) is in itself a heterogeneous disorder as covers multiple different characterized clones. Currently, the treatment is not strictly individualized yet and includes still high-dose chemotherapy with melphalan in transplant-eligible patients. We focused on emerging data on gut microbiota which may be disturbed during chemotherapy and may have a role in the passage of inflammatory mediators through the intestinal barrier. We studied microbiota changes in MM patients and documented the data at diagnosis and after treatment. **Methods:** Stool samples were taken twice, before and after the 4th therapy course. The samples were sequenced using the next-generation sequencing (NGS) method after nucleic acid isolation. OTU (Operational taxonomic unit) tables were prepared using NCBI Blastn version 2.0.12 according to NCBI general 16S bacterial taxonomy reference dated 10.08.2021. The OTU tables were calculated and plotted using R Statistical Computer Language version 4.04 (readr, phyloseq, microbiome, vegan, descry, and ggplot2 packages) to calculate Alpha diversity. Statistical analyses were also performed using R Statistical Computer Language version 4.0.4 and Rstudio IDE 1.4 (tidyverse, readr, xlsx, and ggplot2 packages). The associated pathways were analyzed with the KEGG (Kyoto Encyclopedia of Genes and Genomes) database. **Results:** Fifteen newly diagnosed MM patients enrolled

in the study. The mean age was 61.265±12.129 years (35-75). Gender distribution was M/F: 8/7. Microbiota profile before and after treatment showed a statistically significant change at the phylum level. After treatment, the Bacteroidetes phylum decreased while the Firmicutes phylum showed an increase. Duodenibacillus massiliensis, Hungatella hathewayi, and Paraprevotella clara proved to be also increased.after treatment. The estrogen signaling pathway, aminobenzoate degradation pathway, staurosporine biosynthesis pathway, and One Carbon Pool by Folate was found as important pathways. **Conclusions:** The microbiota diversity is distinctive to each individual and remains relatively unchanged during adult life. It is known that some microbiota contributes to tumorigenesis: Conversely, microbiota may improve the response to chemotherapy by modulating the tumor microenvironment and may be a part of anticancer therapies. As in our study, evaluation of the gut microbiota before MM treatment may help design treatment regimens to modify gut dysbiosis and modulate the response.

Investigation of T-cell fitness and mechanisms of drug resistance in selinexor treated patients with relapsed/refractory multiple myeloma

Yubin Kang[1], Jadee Neff[1], Cristina Gasparetto[1], Xiaobei Wang[1], Andrea Ellero[3], Christopher Walker[3]

[1]Duke University Medical Center; [2]Duke University School of Medicine; [3]Karyopharm Therapeutics Inc

Introduction: Selinexor (SEL) is an oral first-in-class selective exportin 1 (XPO1) inhibitor. SEL in combination with dexamethasone (DEX) and bortezomib is FDA and EMA approved for treatment of patients with multiple myeloma (MM) who have received at least one prior line of therapy. In addition to activating tumor suppressor proteins, non-clinical studies have shown SEL down-regulates immune checkpoints, enhances immune cell surveillance and improves biologic immunotherapies. Herein we investigated the effects of selinexor on MM cell immune markers and the bone marrow (BM) microenvironment in samples from patients with relapsed/refractory MM (RRMM) treated with SEL combinations. **Methods:** Samples from patients enrolled in the STOMP trial, a multi-arm, open-label, Phase 1b/2 study evaluating SEL in combinations with different backbone therapies (NCT02343042), at our institute were included in this post-hoc analysis. Paired BM biopsy samples obtained at the time of initial diagnosis (n=12), immediately before SEL treatment (n=20), and at the end of the study (n=20) were assessed, as well as normal control BM samples (n=12). Samples were stained with CD138, CD3 and CD45 antibodies for morphologic identification then probed with the NanoString GeoMx Digital Spatial Profiling (DSP) Immuno-Oncology multiplex antibody panel for quantitative expression of 96 targets with spatial resolution. XPO1 expression was measured by dual color immunohistochemical (IHC). **Results:** From January 2017 to May 2022, a total of 47 RRMM patients enrolled in the STOMP trial at our institution. The median age was 66 years (ranging from 50 to 77 years) (males: 21 and females 26; African American patients: 17, Caucasian: 28, Hispanic: 2). Of the 47 patients, 10 were in Arm 1 (SEL+DEX+pomalidomide); 15 in Arm 5 (SEL+DEX+daratumumab); and 12 in Arm 6 (SEL+DEX+carfilzomab); with the remaining in other arms. Patients were treated with SEL-based regimens for a median of 270 days (ranging from 35 to 1709 days). Thirty-one patients (66%) achieved PR or better and 34% patients had ≥ VGPR. Thirty-eight patients (81%) discontinued treatment due to disease progression and five patients (11%) discontinued treatment due to toxicities. DSP and IHC are being performed on normal controls, diagnostic samples, and paired pre/post treatment samples from 4 patients in Arm 1, 10 in Arm 5 and 6 in Arm 6. Myeloma cell signaling pathway activations, BM microenvironment immune activity and XPO1 expression will be correlated with treatment response and drug resistance. Detailed and comprehensive results will be presented at the meeting. **Conclusions:** Our study provides insights in how SEL affects the endogenous immune system in the context of MM, with implications for sequencing SEL with immune directed therapies like CAR-T cell treatments. Moreover, our study will identify molecular mechanisms that contribute to drug resistance to SEL, with implications for combination therapies and predictive biomarkers.

Introduction: Previous studies suggest that recovery of polyclonal immunoglobulin from immunoparesis one year after autologous stem cell transplantation (ASCT) in patients with multiple myeloma is a prognostic marker for progression-free survival (PFS) and overall survival (OS). However, this correlation has not been validated in

in the study. The mean age was 61.265±12.129 years (35-75). Gender distribution was M/F: 8/7. Microbiota profile before and after treatment showed a statistically significant change at the phylum level. After treatment, the Bacteroidetes phylum decreased while the Firmicutes phylum showed an increase. Duodenibacillus massiliensis, Hungatella hathewayi, and Paraprevotella clara proved to be also increased.after treatment. The estrogen signaling pathway, aminobenzoate degradation pathway, staurosporine biosynthesis pathway, and One Carbon Pool by Folate was found as important pathways. **Conclusions:** The microbiota diversity is distinctive to each individual and remains relatively unchanged during adult life. It is known that some microbiota contributes to tumorigenesis: Conversely, microbiota may improve the response to chemotherapy by modulating the tumor microenvironment and may be a part of anticancer therapies. As in our study, evaluation of the gut microbiota before MM treatment may help design treatment regimens to modify gut dysbiosis and modulate the response.

Introduction: Selinexor (SEL) is an oral first-in-class selective exportin 1 (XPO1) inhibitor. SEL in combination with dexamethasone (DEX) and bortezomib is FDA and EMA approved for treatment of patients with multiple myeloma (MM) who have received at least one prior line of therapy. In addition to activating tumor suppressor proteins, non-clinical studies have shown SEL down-regulates immune checkpoints, enhances immune cell surveillance and improves biologic immunotherapies. Herein we investigated the effects of selinexor on MM cell immune markers and the bone marrow (BM) microenvironment in samples from patients with relapsed/refractory MM (RRMM) treated with SEL combinations. **Methods:** Samples from patients enrolled in the STOMP trial, a multi-arm, open-label, Phase 1b/2 study evaluating SEL in combinations with different backbone therapies (NCT02343042), at our institute were included in this post-hoc analysis. Paired BM biopsy samples obtained at the time of initial diagnosis (n=12), immediately before SEL treatment (n=20), and at the end of the study (n=20) were assessed, as well as normal control BM samples (n=12). Samples were stained with CD138, CD3 and CD45 antibodies for morphologic identification then probed with the NanoString GeoMx Digital Spatial Profiling (DSP) Immuno-Oncology multiplex antibody panel for quantitative expression of 96 targets with spatial resolution. XPO1 expression was measured by dual color immunohistochemical (IHC). **Results:** From January 2017 to May 2022, a total of 47 RRMM patients enrolled in the STOMP trial at our institution. The median age was 66 years (ranging from 50 to 77 years) (males: 21 and females 26; African American patients: 17, Caucasian: 28, Hispanic: 2). Of the 47 patients, 10 were in Arm 1 (SEL+DEX+pomalidomide); 15 in Arm 5 (SEL+DEX+daratumumab); and 12 in Arm 6 (SEL+DEX+carfilzomab); with the remaining in other arms. Patients were treated with SEL-based regimens for a median of 270 days (ranging from 35 to 1709 days). Thirty-one patients (66%) achieved PR or better and 34% patients had ≥ VGPR. Thirty-eight patients (81%) discontinued treatment due to disease progression and five patients (11%) discontinued treatment due to toxicities. DSP and IHC are being performed on normal controls, diagnostic samples, and paired pre/post treatment samples from 4 patients in Arm 1, 10 in Arm 5 and 6 in Arm 6. Myeloma cell signaling pathway activations, BM microenvironment immune activity and XPO1 expression will be correlated with treatment response and drug resistance. Detailed and comprehensive results will be presented at the meeting. **Conclusions:** Our study provides insights in how SEL affects the endogenous immune system in the context of MM, with implications for sequencing SEL with immune directed therapies like CAR-T cell treatments. Moreover, our study will identify molecular mechanisms that contribute to drug resistance to SEL, with implications for combination therapies and predictive biomarkers.

[1]University of Chicago; [2]Poznań University of Medical Sciences, Poznań, Poland; [3]Wrocław Medical University, Wrocław, Poland; [4]Medical University of Warsaw, Department of Hematology; [5]Medical University of Łódź, Łódź, Poland; [6]Nicolaus Copernicus University in Toruń Ludwik Rydygier, Collegium Medicum in Bydgoszcz, Bydgoszcz, Poland; [7]Medical University of Gdańsk, Gdańsk, Poland; [8]Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland; [9]Department of Experimental Hematooncology, Medical University of Lublin, Lublin, Poland; [10]Poznań University of Medical Sciences, Poznan, Poland; [11]Institute of Hematology and Blood Transfusion, Warsaw; [12]Medical University of Lublin, Lublin, Poland

Introduction: Previous studies suggest that recovery of polyclonal immunoglobulin from immunoparesis one year after autologous stem cell transplantation (ASCT) in patients with multiple myeloma is a prognostic marker for progression-free survival (PFS) and overall survival (OS). However, this correlation has not been validated in

the context of currently utilized extended post-ASCT maintenance therapy. Furthermore, the impact of more intensive regimens, beyond standard single-agent lenalidomide maintenance, on normal plasma cells has not been extensively studied. **Methods:** Using published results of the unplanned interim report (Dytfeld, Lancet Oncology 2023), we performed a longitudinal analysis of polyclonal immunoglobulin concentrations and unique B-cell sequences in patients enrolled in the phase 3 ATLAS trial that randomized 180 subjects to either carfilzomib, lenalidomide, dexamethasone (KRd) or lenalidomide (R) maintenance. In the KRd arm, patients with standard risk and minimal residual disease (MRD) negativity after 6 cycles de-escalated to R alone after cycle 8. **Results:** One year from the initiation of maintenance, complete recovery of uninvolved immunoglobulin was observed in 8/140 (5.7%) evaluable patients and partial recovery (at least one uninvolved immunoglobulin) in 86/140 (61.4%). At least partial recovery was observed in more patients on the R arm (58/66, 87.9%, p< 0.001) and in those who de-escalated from KRd to R (27/38, 71.1%, p< 0.001) compared to the KRd arm (9/36, 25.0%). The concentration of polyclonal immunoglobulin and the number of total unique B-cell sequences were significantly lower in patients who received continuous treatment with KRd throughout the analyzed period (cycles 6, 12, 18, 24, 30, 36). In patients who switched from KRd to R after cycle 8, the concentrations of uninvolved immunoglobulin and B-cell repertoire diversity increased over time after de-escalation, approaching values observed in the control R arm. At MRD assessment after C6, the concentration of uninvolved immunoglobulin was significantly lower among MRD-negative patients (p=0.03). There were no differences in PFS [HR = 1.07 (0.54-2.10), p=0.85] or OS [HR = 1.22 (0.34-4.37), p=0.76] between the patients with at least partial immunoglobulin recovery and the remaining population. The differences in PFS were not significant also when adjusted for the study arm. **Conclusions:** The findings from our study show that polyclonal immunoglobulin recovery one year after ASCT does not have prognostic significance for PFS after extended treatment with KRd versus R, indicating limited prognostic significance of polyclonal immunoglobulins recovery in the context of contemporary landscape of maintenance therapies.

Dynamic immune response in multiple myeloma patients infected with SARS-CoV-2 omicron BA.4/5 subvariant in China

Ziping Li[1], Huiwen He[1], Haolong Li[2], Shuangjiao Liu[3], Fujing Zhang[4], Yongzhe Li[5], Junling Zhuang[3]

[1]Department of Hematology, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing, China; [2]Department of Clinical Laboratory, Peking Union Medical College Hospital; [3]Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences; [4]Department of Hematology, Peking Union Medical College Hospital; [5]Department of Clinical Laboratory, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing, China

Introduction: Patients with multiple myeloma (MM) experienced a high risk of severe disease and mortality during the SARS-CoV-2 pandemic for compromised immunity. However, the immunological characteristics in MM patients with Omicron BA.4/5 subvariant infection remained largely unclear. At the end of 2022, a huge tide of SARS-CoV-2 infection mainly Omicron BA.4/5 developed in China. This study aims to illustrate the dynamic immune response in MM patients after infection to better guide the treatment and vaccination. **Methods:** All MM patients and age- and sex-matched healthy controls (HCs) were recruited from Peking Union Medical College Hospital. Risk factors for COVID-19 infection or hospitalization were analyzed using logistic regression. The titers of neutralizing antibodies toward BA.4/5 subvariant were measured monthly since infection and presented as the inhibition rate (%). **Results:** In total, 218 MM patients (80.7% infected) and 73 infected HCs were enrolled and followed up for 3 months. Of the 176 infected MM patients, 83 (47.2%) were vaccinated, while only 5 (23.8%) of 21 hospitalized patients fulfilling the criteria of severe COVID-19 were vaccinated. Neither univariate nor multivariate analyses identified risk factors associated with infection. Nevertheless, older age, active MM, relapsed/refractory MM (R/RMM), immunotherapy, comorbidity, and non-vaccination were risk factors associated with hospitalization. Older age and immunotherapy were independent risk factors. Compared with HCs and vaccinated patients, unvaccinated MM patients showed significantly lower neutralizing antibody inhibition rates at all 3 time-points. Vaccinated MM patients also exhibited weaker titer of neutralizing antibodies only at the first month while escalating to a similar level as those in HCs later. In MM patients, the maximum antibody level was detected at 2 months. Notably, only 48% unvaccinated MM patients were able to maintain protective antibody levels at 3 months. Moreover, 12/21 (57.1%) hospitalized patients could not develop effective protective antibodies within 1 month after infection. Nineteen (52.8%) over 36 patients receiving immunotherapy also failed to produce sufficient antibodies in the early stages. After one-month break of anti-myeloma therapy, the antibody titer climbed to a similar level as that in patients without immunotherapy. **Conclusions:** Within the first month, MM patients with older age, R/RMM, immunotherapy, comorbidity, and non-vaccination are associated with hospitalization for compromised humoral immunity. Although most MM patients reached the peak of protective antibody at 2 months, high-risk sub-population such as those unvaccinated or older than 65 will be at risk of a second infection after 3 months. The inactivated wild-type vaccine remains effective against the BA.4/5 subvariant in MM patients. Therefore, extra-shots of inactivated SARS-CoV-2 are suggested for high-risk MM patients 3 months after the first infection.

Introduction: Smoldering multiple myeloma is a heterogeneous disease in which patients with high-risk (HRSMM) stratification have high rates of progression to MM, making them suitable candidates for early intervention. Isatuximab, a selective anti-CD38 monoclonal antibody, is currently approved in two combination regimens for relapsed and/or refractory myeloma where, it improved progression free survival over standard of care. Here, we aimed to investigate the impact of single agent Isatuximab in the bone marrow immune microenvironment of HRSMM patients. **Methods:** Patients with HRSMM (based on immunoparesis and ≥95% immunophenotypically abnormal marrow plasma cells) treated in stage 1 of the ISAMAR study with isatuximab monotherapy (NCT02960555) with available formalin-fixed paraffin embedded tissue (FFPE) bone marrow biopsies were included in the study. A previously optimized and validated multiplex immunofluorescence (mIF) panel was developed to assess plasma cells (CD138), macrophages (CD68), immune checkpoints (PD-1, PD-L1), and subsets of T-cells (CD3, CD8, Foxp3, CD45RO). The slides were imaged using Vectra Polaris system (Akoya Biosciences, Marlborough, MA) and the whole tissue was selected for the analysis, and data was consolidated using Spotfire software. Differences in cell densities among different treatment time points: baseline, post-cycle 6 (pC6), post-cycle 18 (pC18), and end of treatment/post-cycle 30 (EOT) were evaluated with Kruskal-Wallis test using SAS Enterprise Guide 7.1. **Results:** Eighteen of 24 patients had available samples. Most patients were female (11/18, 61%), white (16/18, 88%) and had kappa light chain restriction (16/18, 88%). After a median follow-up of 40 months (range: 11-56 months), two patients had complete response, thirteen partial response and two had stable disease. Two patients died of other causes. Efficacy and toxicity were previously reported (Blood (2019) 134 (Supplement_1): 3116.). Sixty samples with a median area of 1.85 mm^2/case and a median number of 8947 cells/case were analyzed by mIF. When comparing different time points of treatment, cases pC6 and EOT had a had a significantly lower cell density of total CD138+ cells (p= 0.0002), though the residual plasma cells had significantly higher staining for CD138+/PD-L1+ (p< 0.0001). Also, there were higher levels of total CD3+ (p< 0.0001), CD3+/PD-1+ (p< 0.0001), CD3+/CD8+ (p< 0.0001), CD3+/Foxp3+/CD8- (p= 0.018), CD3+/CD45RO+ (p< 0.0001), CD3+/CD45RO+/CD8+ (p< 0.0001), CD3+/CD45RO+/CD8- (p=0.0002), and CD68+/PD-L1+ (p< 0.0001). Interestingly, among the patients with partial response only, except for CD3+/Foxp3+/CD8-, pC6 and EOT time points also showed the same statistically significant differences in the immune populations. **Conclusions:** Isatuximab promotes significant immune activation in the bone marrow of patients with HRSMM, characterized by upregulation of different subsets of T-cells, and PD-L1+ plasma cells and macrophages.

Introduction: Infection is the leading cause of death in patients with multiple myeloma (MM). However, the cell-specific extent of baseline immune dysfunction and of the weakened response to vaccination is poorly described. Thus, we aimed to identify the hallmarks of impaired immunity in MM using the COVID-19 mRNA vaccines as a case study. **Methods:** Twenty-eight MM patients and two control groups were studied: 53 patients with a B-cell lymphoproliferative disorder (B-CLPD) and 96 age-matched health care practitioners (HCP). A total of 1,099 peripheral blood and serum samples were collected at baseline, at days 7 and 14 after the first dose, at days 7 and 62 after the second dose, as well as before and after the booster. Immune profiling was performed using multidimensional and computational flow cytometry that systematically analyzed 56 immune cell-types per sample and time point. Serum levels of IgM, IgG and IgA against the receptor-binding domain (RBD) of the spike (S) glycoprotein, S glycoprotein, nucleocapsid (N) and main protease were quantified using a multiplex-microsphere-based flow cytometry assay. SARS-CoV-2-specific CD8 T cells were quantified using a dextramer panel of S, N, membrane, and ORF3 proteins. **Results:** When compared to HCP and B-CLPD, MM patients showed abnormal distribution at baseline and impaired expansion during vaccination of nearly all the 17 B-cell subsets analyzed in this study. Accordingly, anti-RBD IgM, IgA and IgG titers after the second dose were lower in patients with MM vs B-CLPD (P≤.002). When compared to HCP, both MM and B-CLPD patients showed significantly reduced anti-RBD and anti-S antibody levels over time. Significant deviations at baseline and longitudinally were also observed in classical monocytes, and 6 of 30 T-cell subsets. In contrast to HCP, the percentage of virus-specific CD8 T cells after the second dose did not increase in patients with

Immune profiling was performed using multidimensional and computational flow cytometry that systematically analyzed 56 immune cell-types per sample and time point. Serum levels of IgM, IgG and IgA against the receptor-binding domain (RBD) of the spike (S) glycoprotein, S glycoprotein, nucleocapsid (N) and main protease were quantified using a multiplex-microsphere-based flow cytometry assay. SARS-CoV-2-specific CD8 T cells were quantified using a dextramer panel of S, N, membrane, and ORF3 proteins. **Results:** When compared to HCP and B-CLPD, MM patients showed abnormal distribution at baseline and impaired expansion during vaccination of nearly all the 17 B-cell subsets analyzed in this study. Accordingly, anti-RBD IgM, IgA and IgG titers after the second dose were lower in patients with MM vs B-CLPD (P≤.002). When compared to HCP, both MM and B-CLPD patients showed significantly reduced anti-RBD and anti-S antibody levels over time. Significant deviations at baseline and longitudinally were also observed in classical monocytes, and 6 of 30 T-cell subsets. In contrast to HCP, the percentage of virus-specific CD8 T cells after the second dose did not increase in patients with

MM and B-CLPD. Importantly, the booster increased anti-RBD IgG levels (20,184 to 186,629 IU/mL, P<.001) and virus-specific cells (0.08 to 0.14% among CD8 T cells, P=.02) in HCP, but not in MM and B-CLPD (P≥.14). Furthermore, the booster induced virus-specific CD8 T cell differentiation into an effector memory phenotype in HCP, whereas no antigen-dependent differentiation was observed in patients with MM and B-CLPD. Based on differences in immune-cell distribution using HCP as a reference, we calculated an immune dysregulation longitudinal cumulative score in each individual that included 48,496 parameters. Up to 34% MM and 17% B-CLPD patients showed notable immune dysregulation. Among them, 75% and 33%, respectively, had low seroconversion after the second dose. **Conclusions:** We provide an atlas of the immune dysfunction in MM patients and how it affects the efficacy of vaccination strategies such as for COVID-19. The schedule of vaccine doses may thus benefit from individualization according to patients' immune status, which could act as a surrogate of host, tumor and treatment-related immune dysfunction.

Introduction: Despite the substantive advancements that occurred in multiple myeloma (MM) therapy over the past years, the highly heterogenous treatment response hinders reliable prognosis and tailored therapeutics, highlighting the urgent need for the delineation of innovative prognostic markers to be incorporated into clinical care. In this context, high-throughput techniques have unveiled microRNAs (miRNAs), as potent post-transcriptional regulators of gene expression with critical implications in cancer onset and progression. The emergence of these techniques revealed that miRNAs are deregulated in all human tumors and highlighted their utility as potential prognostic indicators. Herein, using miRNA-seq we have investigated deregulated miRNAs between R-ISS III vs R-ISS I/II MM patients, aiming to reveal potential MM-related miRNAs able to improve patients' risk stratification and prognosis. **Methods:** Bone marrow aspiration (BMA) samples were collected from 121 MM patients at diagnosis. Mononuclear cells were isolated using Ficoll-Paque, while CD138+ plasma cells were positively selected using magnetic beads with anti-CD138 mAbs. Next, miRNA-seq was performed in CD138+ plasma cells from 24 MM patients (8 R-ISS I, 8 R-ISS II and 8 R-ISS III). Based on miRNA-seq, the prognostic impact of both miR-221-3p and miR-222-3p was further evaluated, for the first time, in our MM screening cohort. Subsequently, RNA extraction, 3'-end polyadenylation and reverse transcription, miR-221-3p and miR-222-3p levels were evaluated using in-house developed qPCR assays. Finally, patients' mortality and disease progression were assessed as clinical endpoints for survival analysis. **Results:** miRNA-seq revealed both miR-221 and miR-222 to be concurrently downregulated in R-ISS III vs R-ISS I/II patients (miR-221: Fold Change;FC=0.356; log2(FC)=-1.48; miR-222: FC=0.357; log2(FC)=-1.48). In our screening cohort, miR-221 loss was associated with a significantly higher risk of short-term disease progression (p=0.002) and poor overall survival following treatment (p=0.040), while univariate Cox regression analysis confirmed the adverse prognostic value of miR-221 loss in patients' overall survival (HR=2.158; p=0.047) and disease progression (HR=2.386; p=0.004). Along the same lines, miR-222 loss was linked with poor overall survival (p=0.012) and higher risk of short-term disease progression (p=0.008), while univariate Cox regression analysis confirmed miR-222 loss as an unfavorable prognostic indicator of patients' overall survival (HR=2.569; p=0.016) and short-term disease progression (HR=2.143; p=0.011) in MM patients. **Conclusions:** Ultimately, we identified the loss of miR-221/222 in CD138+ plasma cells as a powerful indicator of adverse disease outcome, ameliorating tailored patient's management.

Introduction: The bone marrow microenvironment plays a crucial role in the development of drug resistance in multiple myeloma (MM). In recent years, metabolomics have become of great importance in the search for new treatment strategies in cancer. Cancer cells are highly capable of adapting their metabolism to increasing energy demands. We have previously shown that MM cells are dependent on proline synthesis, and inhibition of proline production by PYCR1 interference increased bortezomib sensitivity both in vitro and in vivo. Surrounding stromal cells in the microenvironment support tumor growth. As PYCR1 is highly expressed in stromal cells, we wondered whether the stromal cells produce and secrete proline into the microenvironment to support and stimulate MM cell metabolism and proliferation. In this study,

MM and B-CLPD. Importantly, the booster increased anti-RBD IgG levels (20,184 to 186,629 IU/mL, P<.001) and virus-specific cells (0.08 to 0.14% among CD8 T cells, P=.02) in HCP, but not in MM and B-CLPD (P≥.14). Furthermore, the booster induced virus-specific CD8 T cell differentiation into an effector memory phenotype in HCP, whereas no antigen-dependent differentiation was observed in patients with MM and B-CLPD. Introduction: The bone marrow microenvironment plays a crucial role in the development of drug resistance in multiple myeloma (MM). In recent years, metabolomics have become of great importance in the search for new treatment strategies in cancer. Cancer cells are highly capable of adapting their metabolism to increasing energy demands. We have previously shown that MM cells are dependent on proline synthesis, and inhibition of proline production by PYCR1 interference increased bortezomib sensitivity both in vitro and in vivo. Surrounding stromal cells in the microenvironment support tumor growth. As PYCR1 is highly expressed in stromal cells, we wondered whether the stromal cells produce and secrete proline into the microenvironment to support and stimulate MM cell metabolism and proliferation. In this study,

we investigated whether inhibition of proline production by stromal cells negatively affects myeloma cell viability. **Methods:** PYCR1 expression was investigated by the use of microarray data from the Heidelberg/Montpellier cohort. For in vitro experiments, the human MM cell lines OPM-2 and XG-2 and the human stromal cell line HS-5 were used. Data was confirmed on primary CD138+ MM cells. To obtain primary stromal cells, the CD138- fraction from primary patient samples was plated out in fresh medium. After 48h, the medium was refreshed and all adherent cells were further cultured and used as primary stromal cells. PYCR1 expression in HS-5 cells was reduced through siRNA. Hypoxic culture (< 1% O2) was established through hypoxia chambers. Angiogenesis and cytokine arrays were performed to identify changes in cytokine and growth factor secretion. Protein expression was measured by western blot. Viability was assessed by CellTiterGlo assay. **Results:** Gene expression analysis showed high RNA expression of PYCR1 in healthy BMPCs, plasma cells from MGUS and MM patients, but also in bone marrow stromal cells (BMSCs). PYCR1 expression was low or absent in other cell types, including T cells, osteoclasts, monocytic and granulocytic cells. On protein level, we also confirmed PYCR1 expression in MM cells (CD138+), the CD138- fraction and cultured primary stromal cells. Moreover, PYCR1 expression increased upon hypoxic culture in primary stromal cells and HS-5. PYCR1 knockdown in HS-5 did not affect the viability of the stromal cells, but did reduce their protective effect on OPM2 and XG-2 cells against bortezomib. Further analysis of the conditioned medium of the stromal cells via angiogenesis and cytokine arrays identified a reduced secretion of IL-1β, activin A and IL-13 upon PYCR1 interference. In vivo, PYCR1 inhibition enhanced bortezomib-mediated effects on tumor burden. **Conclusions:** This study indicates that PYCR1 is a potential target in the MM tumor microenvironment, to not only alter metabolite availability for MM cells, but to also reduce cytokine and growth factor release from stromal cells, thereby annihilating their protective effect on MM cells.

Introduction: A pivotal step to achieving better clinical responses is the early diagnosis of monoclonal disorders that can progress to multiple myeloma (MM), such as monoclonal gammopathy of undetermined significance (MGUS) and smoldering MM (SMM). A class of RNA molecules with regulatory potential in MM are circular RNAs (circRNAs). However, our knowledge regarding circRNAs produced from apoptosis-related genes is limited. Prompted by this, we aimed to identify novel circRNAs of the BCL2L12 gene that are expressed in MM cells and develop a sensitive quantification protocol for circRNAs of interest in patients' samples. **Methods:** Total RNA was extracted from 3 cell lines (L-363, H929, and U266) and reverse-transcribed using random hexamers. Then, pairs of divergent primers were designed, and nested PCR protocols were implemented. Next, targeted 3rd-generation sequencing with nanopore technology was performed. Novel circRNA sequences were identified using in-house–built Perl-based algorithms. Bioinformatics analysis followed to predict the interactions of the novel BCL2L12 circRNAs, utilizing publicly available tools and databases, such as miRDB and dbDEMC. Then, circ-BCL2L12-36 and circ-BCL2L12-38 were chosen among the circRNAs that were common among all MM cell lines for further investigation. Total RNA was extracted from CD138+ plasma cells of 28 MGUS, 30 SMM, and 103 MM patients, and cDNA synthesis was performed. Subsequently, we developed in-house real-time qPCR assays, using specific divergent primers that span the circRNAs back-splice junction, to quantify these circRNAs in all samples. GAPDH was used as a reference gene for qPCR data normalization. **Results:** We identified 36 novel circRNAs deriving from the BCL2L12 gene, 4 of which are common among all MM cell lines. The structures of these novel circRNAs showed remarkable diversity, comprising currently annotated exons, as well as truncated exons and genomic regions that were not represented in BCL2L12 transcripts so far. Moreover, several BCL2L12 circRNAs are predicted to sponge miRNAs with a key role in MM, including miR-181 family members that have been associated with chemosensitivity, miR-195-5p which is correlated with thoracic lesions, and miR-455-3p that was decreased in MM patients with renal impairment. Furthermore, circ-BCL2L12-36 is expressed in 60% of patient samples, while circ-BCL2L12-38 is expressed in 84.5% of samples. **Conclusions:** In this study, 36 novel circRNAs of the BCL2L12 gene were annotated. These circRNAs are formed through various alternative back-splicing events of the known BCL2L12 exons. All novel circRNAs are predicted to bind miRNAs that are intricately implicated in MM. By sequestering these miRNAs, BCL2L12 circRNAs may affect patients' progression risk, response to therapy, and survival outcome. Finally, circ-BCL2L12-36 and circ-BCL2L12-38 were also successfully quantified and found to be expressed in the CD138+ cells of patients at different disease stages.

Introduction: Modern therapies for multiple myeloma (MM) rely on the immune system for their effectiveness and positive outcomes. Dysregulation in the immune compartment can promote disease progression and hamper the effectiveness of immune-based therapies. In this study for the characterization of bone marrow (BM) and its association with the kinetics of MM (Rapid Progression (RPs) = PFS4 years), we performed Single Cell Profiling on BM samples from the Multiple Myeloma Research Foundation CoMMpass cohort. **Methods:** Frozen CD138 negative fraction of BM samples from MM patients enrolled in the CoMMpass clinical trial (NCT01454297) underwent scRNA-seq at four different medical centers/Universities. ScRNA-seq data from 361 BM samples of 263 MM patients, collected at different time points (263 disease diagnosis (Dx), 59 relapses, 32 remissions, 7 other) were generated in phase I of the study. The scRNA-seq data were aligned and quality-controlled, doublet filtered, normalized, and batch-corrected before unsupervised and supervised analysis. The statistical analysis of annotated cellular clusters comparing RPs and NPs identified cell types, genes, and pathways associated with rapid progression. **Results:** ScRNA-seq on BM samples collected at Dx from 263 MM patients generated high-quality profiles of 886,329 cells. The unsupervised analysis yielded 106 clusters corresponding to myeloid, lymphoid, and erythroid lineages. The cellular proportion analysis comparing rapid progressors (n=67) and non-progressors (n=83) depicted significant differences (P1, P< 0.01), while NPs display significant enrichment of naïve markers (LTB, SELL, TCF7) associated with better outcomes. RP-enriched, GZMB+ cellular populations also lacked CD27 and CD28 expression, suggesting they are terminally and clonally expanded effector cells. **Conclusions:** Based on single-cell findings, the expansion of a senescent CD8+ effector population along with the reduction of the memory T cell population might be resulting in a lower effectiveness of immunotherapies in rapid progressors. This in-depth characterization of the BM microenvironment might assist in developing further therapies directed toward rapid progressors with inflammaging immune ecosystems.

Introduction: Monoclonal Gammopathy of Undetermined Significance (MGUS) is a premalignant stage that eventually all multiple myeloma (MM) patients have suffered. According to the Mayo Clinic, risk factors to progression include M-protein size and isotype as well as free light chain (FLC) ratio. Classic immunoparesis is defined as the suppression of uninvolved immunoglobulins (Igs) and its role as MGUS to MM progression factor remains controversial. Nowadays, we can measure the uninvolved heavy/light chain pair of the same immunoglobulin (uHLC). However, little data have been reported regarding its role as a progression factor from MGUS to MM. The aim of this prospective, single center study was to assess the prognostic value of uHLC suppression (Isotype Matched Immunoparesis or IMI) in MGUS to MM progression. **Methods:** The study group was composed by 232 stored serum samples from 116 MGUS patients attending our hospital. Light chain only MGUS patients were not included in the analysis. We analyzed classic immunoglobulins and uHLC in the laboratory of our institution at diagnosis and in each routine visit. MGUS risk progression factors were assessed following Mayo Clinic guidelines. We considered classic immunoparesis (IP) at diagnosis when one or more uninvolved classic Ig were under lower limit of normality (LLN) and IMI when uHLC was under LLN. We defined the decrease of uHLC (duHLC) as the rate of change of uHLC concentration in the last follow-up or at progression compared to uHLC concentration at diagnosis. Recovery of uHLC was considered when suppressed uHLC at diagnosis reached at least LLN+10% in the last follow-up or at progression. **Results:** At diagnosis we found classic IP in 32% (37/116) of patients, whereas IMI was found on 43% (50/116) of them. Both classic IP and IMI were more common in IgA patients (40% and 83%, respectively) in comparison to IgG (30% and 41%) or IgM (33% and 21% respectively) patients. Interestingly, the presence of IMI was more frequent in patients with a higher risk of progression to MM, thus, IMI was only found in 31% of patients with no risk factors whereas the percentage increased as the number of risk factors did (1 risk factor 43% of patients and 2 risk factors 56%). Furthermore, MGUS patients who presented duHLC>50% had a higher risk of progression to MM (p=0.0067) with a median of progression of 8.35 years whereas in patients with a duHLC≤50% the median was not reached. Additionally, patients with duHLC>90% presented a median to progression of 5.5 years (p=0.047). Finally, MGUS patients that did not recover uHLC had a higher risk of progression to MM (p=0.029) with a hazard ratio of 3.821. **Conclusions:** Both uHLC decrease and recovery of uHLC have shown to be a risk factor in the progression from MGUS to MM in our patient cohort. Therefore, the measurement of uHLC in MGUS patients could be an additional tool to predict progression to MM.

Additionally, patients with duHLC>90% presented a median to progression of 5.5 years (p=0.047). Finally, MGUS patients that did not recover uHLC had a higher risk of progression to MM (p=0.029) with a hazard ratio of 3.821. **Conclusions:** Both uHLC decrease and recovery of uHLC have shown to be a risk factor in the progression from MGUS to MM in our patient cohort. Therefore, the measurement of uHLC in MGUS patients could be an additional tool to predict progression to MM.

[1]Department of Internal Medicine II, University Hospital Würzburg, Würzburg, Germany; [2]IZKF Group Tissue Regeneration in Musculoskeletal Diseases, University Hospital Würzburg, Würzburg Germany; [3]Department of Musculoskeletal Tissue Regeneration, Orthopedic Clinic König-Ludwig-Haus, University of Würzburg, Germany; [4]Centre of Translational Oral Research (TOR)-Tissue Engineering group, Department of Clinical Dentistry, University of Bergen, Norway

Introduction: Myeloma bone disease (MBD) is a hallmark of MM and affects 80% of MM patients. Current treatments do not fully regenerate osteolytic lesions, even in the absence of MM cells. We showed that tibial compressive loading prevents bone destruction, and reduces MM growth and dissemination in the MOPC315. BM mouse model. In this study, we established an in vitro 3D bioreactor model for MM to characterize the mechanobiological processes in osteocytes, the main mechanosensors controlling bone remodeling. **Methods:** Osteocytic IDG-SW3 cells were seeded onto three different scaffolds: decellularized and partially demineralized dBone derived from human femoral heads, synthetic ß-tricalcium phosphate (ß-TCP), and synthetic poly(L-lactide-co-trimethylene carbonate) (LTMC). To assess the colonization efficiency under static and dynamic conditions in the bioreactor, viability, and growth of IDG-SW3 cells were evaluated by MTT, PicoGreen assay, and LIVE/DEAD staining. Osteocytic differentiation was confirmed by alkaline phosphatase (ALP) staining and gene expression analysis of alkaline phosphatase (Alpl), sclerostin (Sost), and dentin matrix protein 1 (Dmp-1). Biophysical stimulation was exerted by compressing the scaffolds with a movable arm. Expression of the mechanoresponsive genes FBJ osteosarcoma oncogene (Fos) and cyclooxygenase-2 (Cox2) was analyzed to determine the mechanoresponse. **Results:** In all scaffolds, reproducible cell seeding capacity was detected with dBone scaffolds exhibiting donor variability. Homogeneous distribution and high density were achieved in dBone and LTMC scaffolds under static and dynamic conditions, whereas the cells colonized only on the top of the ß-TCP scaffolds and barely grew through after ten days. ß-TCP scaffolds demonstrated low mechanical loading capacity and disintegrated upon compression. We found that osteocytic differentiation was most efficiently induced under dynamic conditions, as evidenced by upregulation of the differentiation markers Alpl, Sost, Dmp-1, and by ALP staining. Fos and Cox2 were induced through mechanical loading of the LTMC scaffolds. **Conclusions:** The established bioreactor system is suitable to study molecular changes in osteocytes caused by MM and mechanical loading. Differences in pore size, porosity, and interconnectivity of these scaffolds affect the growth and cell migration of IDG-SW3 cells. Since the ß-TCP scaffolds did not show a homogenous distribution of the cells with also insufficient mechanical stability and the dBones exhibited inter- and intra-donor variability, the LTMC scaffolds provided the most reliable results. We will use the bioreactor in future studies to characterize the molecular mechanisms of mechanotransduction in osteocytes in the presence of MM cells and their supernatant to evaluate whether secreted factors of MM cells affect the differentiation and function of osteocytes.

3D organoid model: using primary cells to study therapeutic effects on patients' myeloma tumor niche

Cesar Rodriguez[1], Hanadi Rashad[2], Giovanni Insuasti[3], Graca Almeida-Porada[2]

[1]Icahn School of Medicine at Mount Sinai; [2]Wake Forest Institute of Regenerative Medicine; [3]Health Wake Forest Baptist

Introduction: Preclinical models have been the backbone for drug development and learning about cancer biology. The inability to properly recapitulate the tumor niche and the difficulty to use primary cells have been great detrimental factors when translating results from the bench to the bedside. We have previously reported results of an ex-vivo 3D organoid cell model with biomimetic microenvironment that allowed prolonged cell survival of primary myeloma cells for up to 14 days in co-cultures and chemosensitivity results. We now present the effects different drug conditions have on both the plasma cells as well as the immune compartment found in primary patient samples. **Methods:** After obtaining informed consent, we obtained bone marrow aspirate samples from patients with relapsed multiple myeloma. Using previously described technique, mononuclear cells were co-cultured cultured with stroma in a Matrigel scaffold. Each organoid containing 200,000 cells was plated on an individual well and nourished with enriched culture media. Batches of organoids from the same patient sample were exposed to three different chemotherapy agents (bortezomib 5 nM and 10nM, lenalidomide 50 µM and 100 µM, selinexor 10 µM and 30 µM) on day 5 of experiment and removed 72 hours later. Different timepoints prior to drug exposure (day 5), at the end of drug exposure (day 8), and six days later (day 14) were used to perform viability/proliferation assays with Alamar Blue and flow cytometry to assess different cellular compartments, specifically plasma cells and part of the immune repertoire (CD4, CD8, and NK cells). **Results:** Primary cells from bone marrow aspirates remained viable for the duration of the experiment (14 days). Alamar blue showed proliferation in the control group while significant differences were seen in viability based on agent and concentration (Image 1). When looking at flow cytometry data, we see different impact in T cell and NK cell found in the tumor niche (Image 2, 3, 4, 5, 6). **Conclusions:** While conventional preclinical models have been a cornerstone to drug development and advances in medicine, the current development of immunotherapies, including cellular therapy require a better physiological representation of the tumor niche. Organoid models

Differential peripheral cytokine profile and tumor microenvironment in patients with or without a history of BCMA-directed therapy prior to elranatamab: analysis of MagnetisMM-3

Paula Rodriguez-Otero[1], Mohamad Mohty[2], Nizar Bahlis[3], Michael Tomasson[4], Hang Quach[5], Sangeetha Sathiah[6], Douglas Robinson[7], Umberto Conte[7], Thomas O'Brien[7], Katja Weisel[8]

[1]Clinica Universidad de Navarra, Pamplona, Spain; [2]Sorbonne University, Saint-Antoine Hospital, AP-HP INSERM UMRs 938, Paris, France; [3]Arnie Charbonneau Cancer Institute - University of Calgary; [4]Internal Medicine-Hematology, Oncology, and Blood and Marrow Transplantation, University of Iowa; [5]St Vincent's Hospital Melbourne, University of Melbourne, VIC, Australia; [6]Pfizer Healthcare India Private Ltd; [7]Pfizer Inc; [8]University Medical Center of Hamburg-Eppendorf, Hamburg, Germany

Introduction: MagnetisMM-3 (NCT04649359) is a phase 2 study of elranatamab in patients (pts) with relapsed/refractory multiple myeloma. Here, we compare the peripheral cytokine profile, its correlation with cytokine release syndrome (CRS) and tumor microenvironment (TME) in pts naïve to BCMA-directed therapy (Cohort A, n=123) vs. pts with prior exposure to BCMA-directed therapy (Cohort B, n=64) in MagnetisMM-3. **Methods:** Pts received subcutaneous elranatamab with 2-step-up doses of 12/32 mg followed by 76 mg QW. Serum samples were collected during cycle 1, and levels of 45 cytokines were analyzed by proximity extension assay and a longitudinal mixed effects model was applied to each cytokine separately. LM22 immune cell signatures were derived from gene expression analysis of bone marrow aspirate (BMA) collected at baseline. Clinical data cutoff was January 2023 with median follow up of 12.0 months. **Results:** There were no significant differences (≥2-fold; p< 0.05) in baseline levels of cytokines between BCMA-naïve and BCMA-exposed pts and no baseline cytokine correlated with the development of CRS in either group. In BCMA naïve patients, 7 cytokines (IL-6, IFN-g, IL-10, TNF-a, CCL-8, IL-27, IL-2) were differentially expressed (≥3-fold; unadjusted p< 0.05) during treatment in pts with CRS whereas in BCMA-exposed pts, only 6 cytokines (IL-10, IL-1b, IL-13, IL-18, TSL and IL-2) were differentially expressed in pts with CRS. Notably, the difference in cytokine expression in BCMA-exposed pts experiencing CRS was often smaller and/or peaked at different times than in BCMA-naïve pts, suggesting an altered cytokine response in pts with prior BCMA-directed therapy. Patients with prior exposure to a BCMA agent were treated either with an ADC (n=46) or a CAR-T agent (n=21). At baseline, there were no significant differences (≥2-fold; p< 0.05) in cytokine levels between the ADC vs. CAR-T subgroups. In patients that experienced CRS only two cytokines were differentially expressed (≥3-fold; p< 0.05) in pts experiencing CRS: higher IL-4 in the CAR-T subgroup (3.15-fold at C1D5; p=0.002) and higher IL-1b (3.2-fold at C1D2; p=0.011 and 3.4-fold at C1D15; p=0.001) in the ADC subgroup. Gene expression analysis of bulk BMA samples at baseline revealed a different immune cell signature with less abundant subsets of inferred T-cell populations in BCMA-exposed pts compared to BCMA naïve pts. The difference was driven by a lower abundance of T-cell population signatures in the CAR-T relative to the ADC subgroup, suggesting inherent differences in the baseline immune TME in these groups. Additionally, no significant association between CRS and baseline LM22 immune cell signatures in BCMA-naïve vs. BCMA-exposed pts was observed. **Conclusions:** Cytokine induction in pts experiencing CRS in prior-exposed BCMA patients was often different compared to BCMA naïve patients. Distinct immune cell signatures derived from gene expression analysis of the TME were observed in pts with prior BCMA-directed CAR-T therapy.

Elevated LAG-3 expression in plasma cells and lymphoid subpopulations at distinct stages of multiple myeloma disease progression

Hatice Satilmis[1], Niels Vandewalle[1], Emma Verheye[1], Rong Fan[1], Elke De Bruyne[1], Eline Menu[1], Nick Devoogdt[1], Karin Vanderkerken[2], Karine Breckpot[1], Kim De Veirman[2]

[1]Department of Hematology and Immunology-Myeloma Center Brussels, Vrije Universiteit Brussel, Brussels, Belgium; [2]Laboratory of In Vivo Cellular and Molecular Imaging Laboratory, Vrije Universiteit Brussel, Brussels, Belgium

Introduction: Immunotherapy dramatically changed the survival and quality of life of Multiple Myeloma (MM) patients. Despite the potential for durable responses, the majority of patients are still confronted with disease relapse. Immune checkpoints (ICPs) such as PD-1/PD-L1 were previously found to be overexpressed in MM, however targeting of these ICPs did not result in any clinical success so far. More recent in vitro studies suggested that blockade of the ICP LAG-3 could increase effector T-cell responses in the tumor microenvironment of MM patients. In this study, we aimed to further elucidate the expression of LAG-3 in myeloid and lymphoid subsets during MM disease progression using non-invasive imaging and flow cytometry in the immunocompetent 5T33MM model. **Methods:** Previous developed anti-LAG-3 nanobodies were used to non-invasively image the LAG-3 expression in vivo. Anti-LAG-3 nanobodies and a control nanobody (R3B23) were radiolabeled with 99mTechnetium and injected in naïve and tumor-bearing C57BL/KaLwRij mice at different time points post-tumor inoculation (7 days post-injection (DPI), 14 DPI and 21 DPI). SPECT/CT imaging and organ biodistribution studies using a γ-counter were performed. LAG-3 expression on different immune subtypes was further evaluated using multi-parameter flow cytometry. Statistical differences were assessed using a One-way ANOVA, with p< 0.05 considered as statistically significant. **Results:** While no clear

from primary patient samples provide an environment that allows evaluation of different study conditions and its impact not just on the patient's own myeloma cells, but their immune compartment as well. Additional studies to assess its application in T-cell redirecting therapy and other novel immunotherapies using this model is warranted to correlate with clinical outcomes.

Elevated LAG-3 expression in plasma cells and lymphoid subpopulations at distinct stages of multiple myeloma disease progression

Hatice Satilmis[1], Niels Vandewalle[1], Emma Verheye[1], Rong Fan[1], Elke De Bruyne[1], Eline Menu[1], Nick Devoogdt[1], Karin Vanderkerken[2], Karine Breckpot[1], Kim De Veirman[2]

[1]Department of Hematology and Immunology-Myeloma Center Brussels, Vrije Universiteit Brussel, Brussels, Belgium; [2]Laboratory of In Vivo Cellular and Molecular Imaging Laboratory, Vrije Universiteit Brussel, Brussels, Belgium

Introduction: Immunotherapy dramatically changed the survival and quality of life of Multiple Myeloma (MM) patients. Despite the potential for durable responses, the majority of patients are still confronted with disease relapse. Immune checkpoints (ICPs) such as PD-1/PD-L1 were previously found to be overexpressed in MM, however targeting of these ICPs did not result in any clinical success so far. More recent in vitro studies suggested that blockade of the ICP LAG-3 could increase effector T-cell responses in the tumor microenvironment of MM patients. In this study, we aimed to further elucidate the expression of LAG-3 in myeloid and lymphoid subsets during MM disease progression using non-invasive imaging and flow cytometry in the immunocompetent 5T33MM model. **Methods:** Previous developed anti-LAG-3 nanobodies were used to non-invasively image the LAG-3 expression in vivo. Anti-LAG-3 nanobodies and a control nanobody (R3B23) were radiolabeled with 99mTechnetium and injected in naïve and tumor-bearing C57BL/KaLwRij mice at different time points post-tumor inoculation (7 days post-injection (DPI), 14 DPI and 21 DPI). SPECT/CT imaging and organ biodistribution studies using a γ-counter were performed. LAG-3 expression on different immune subtypes was further evaluated using multi-parameter flow cytometry. Statistical differences were assessed using a One-way ANOVA, with p< 0.05 considered as statistically significant. **Results:** While no clear

differences could be observed on SPECT/CT images of naïve and MM mice, ex vivo biodistribution analysis showed a significant uptake and increase of anti-LAG-3 nanobodies in the bone and spleen at 14 DPI (20-40% tumor load) and 21 DPI (60-80% tumor load) compared to naïve mice. Within the CD45+ population in the spleen, we observed an increase in neutrophils (CD11b+Ly6G+) and monocytes (CD11b+Ly6G) during MM disease progression. In the bone marrow (BM), we observed a significant increase in CD4+ T-cells and CD8+ T-cells at 14 DPI and 21 DPI within the CD45+ cell fraction. Flow cytometry analysis revealed a significant higher LAG-3 expression on MM cells upon disease progression. Within the lymphoid population, LAG-3 expression was increased in BM-derived CD8+ T-cells, while this remained unaffected in splenic T-cells. LAG-3 expression generally decreased in almost all myeloid subsets (e.g. macrophages, dendritic cells (DCs)), except splenic monocytes and plasmacytoid DCs, during MM disease progression. **Conclusions:** Ex vivo biodistribution data revealed increased LAG-3 expression and nanobody uptake in MM-infiltrating organs. Using flow cytometry, a high expression of LAG-3 was observed in MM cells and lymphoid cells, which significantly increased within BM-derived CD8+ T-cells at end-stage of disease. Altogether, these data illustrate increased expression of LAG-3 upon disease progression and fosters the evaluation of LAG-3 blocking therapies, particularly in the context of immunotherapeutic approaches in MM.

Introduction: Prior studies have suggested that immune dysregulation can already be observed in patients with Monoclonal Gammopathy of Undetermined Significance (MGUS); however, it is unclear (i) how it compares to the dysregulation observed in

differences could be observed on SPECT/CT images of naïve and MM mice, ex vivo biodistribution analysis showed a significant uptake and increase of anti-LAG-3 nanobodies in the bone and spleen at 14 DPI (20-40% tumor load) and 21 DPI (60-80% tumor load) compared to naïve mice. Within the CD45+ population in the spleen, we observed an increase in neutrophils (CD11b+Ly6G+) and monocytes (CD11b+Ly6G) during MM disease progression. In the bone marrow (BM), we observed a significant increase in CD4+ T-cells and CD8+ T-cells at 14 DPI and 21 DPI within the CD45+ cell fraction. Flow cytometry analysis revealed a significant higher LAG-3 expression on MM cells upon disease progression. Within the lymphoid population, LAG-3 expression was increased in BM-derived CD8+ T-cells, while this remained unaffected in splenic T-cells. LAG-3 expression generally decreased in almost all myeloid subsets (e.g. macrophages, dendritic cells (DCs)), except splenic monocytes and plasmacytoid DCs, during MM disease progression. **Conclusions:** Ex vivo biodistribution data revealed increased LAG-3 expression and nanobody uptake in MM-infiltrating organs. Introduction: Prior studies have suggested that immune dysregulation can already be observed in patients with Monoclonal Gammopathy of Undetermined Significance (MGUS); however, it is unclear (i) how it compares to the dysregulation observed in

patients with Smoldering Multiple Myeloma (SMM), (ii) which populations may directly interact with the tumor, and (iii) which types of dysregulation may be true hallmarks of disease. **Methods:** Here, we present results from the largest single-cell RNA-sequencing cohort (n=398) of bone marrow (BM) CD138-negative (n=271) and peripheral blood mononuclear cell samples (n=127) from patients with monoclonal gammopathies [MGUS, n=51; SMM, n=226; asymptomatic Waldenstrom's Macroglobulinemia (AWM), n=28; Multiple Myeloma (MM), n=28; healthy donors (HD), n=61]. Libraries were prepared with the Chromium Single-cell 5' Gene Expression kit by 10X Genomics and sequenced at the Genomics Platform of the Broad Institute of MIT and Harvard (Cambridge, MA). **Results:** Overall, we profiled ~2.5M immune cells. Remarkably, despite their early stage, patients with MGUS presented extensive immune dysregulation compared to HD, suggesting that compositional changes may be established early on and that changes in gene expression and functionality may underlie progression. To identify subpopulations that are more likely to interact with tumor cells, we compared their abundance between matched BM CD138-positive and CD138-negative fractions in patients and HD. In patients, megakaryocytes were enriched in the CD138-positive fraction, an interaction previously shown to promote MM progression. Pro-B cells, pre-B cells, and memory B cells were enriched in the CD138-positive fraction of patients as well, suggesting that they could be involved in the clonal population or perhaps supporting its growth. Notably, granzyme K-expressing CD8+ T cells were significantly enriched in the CD138-positive fraction of patients, which is consistent with prior studies implicating this population in progression and response to therapy. To identify immune hallmarks of disease, we compared immune cell abundance and expression profiles between patients with SMM and patients with AWM, a different but related malignancy of the BM. We found that the significant increase in Th17 cells and Tregs we observed in patients with SMM is largely specific to myeloma, suggesting that these populations may be critical in sustaining MM cells. Furthermore, we observed myeloma-specific downregulation of the transcription factor CEBPD and its downstream targets, S100A8 and S100A9, in monocytes. **Conclusions:** In the largest to date single-cell RNA-sequencing study of immune cells from patients with monoclonal gammopathies, we have comprehensively mapped alterations in BM immune cell composition in patients with MGUS, identified subpopulations that are more likely to interact directly with tumor cells in the BM microenvironment, and described immune hallmarks of disease.

Introduction: Despite the notable progress that has been achieved in the realm of multiple myeloma (MM) treatment and monitoring, the persistence of elevated relapse rates and therapy resistance remain a substantial hindrance to the effective management of the disease, highlighting the urgent need for the elucidation of molecular indicators supporting tailored patient's management. In this context, tRNA-derived fragments (tRFs), and specifically 3'U-tRFs, represent a novel class of small non-coding RNAs (ncRNAs), derived from pre-mature tRNAs, gathering attention due to their vital roles in regulating gene expression and their potential clinical utility in cancer prognosis and risk stratification. Overall, the aim of the present study was to investigate the involvement of 3'U-tRFHisGTG in MM. **Methods:** Bone marrow aspiration (BMA) samples were collected from 136 MM, 15 smoldering MM (sMM) and 15 monoclonal gammopathy of undetermined significance (MGUS) patients at diagnosis. Mononuclear cells were extracted from BM aspirates using Ficoll-Paque, and CD138+ plasma cells were separated through magnetic cell sorting, using immunomagnetic beads coated with anti-CD138 monoclonal antibodies. Based on target prediction and Gene Ontology (GO) enrichment, 3'U-tRFHisGTG was further evaluated for the first time in CD138+ plasma cells from the total study population. Following, total RNA extraction, polyadenylation at 3'-end, and reverse transcription using an oligo(dT) adapter primer, 3'U-tRFHisGTG levels were estimated through in-house qPCR. Finally, overall survival (OS) and progression-free survival (PFS) were evaluated, while internal validation was accomplished by bootstrap Cox proportional regression analysis. **Results:** In silico analysis unveiled the implication of 3'U-tRFHisGTG in cancer associated processes including, protein modification processes (protein acetylation), and autophagosome assembly. Our findings demonstrated the downregulated 3'U-tRFHisGTG levels in MM compared to its precursor stages sMM/MGUS (p=0.036), while focusing on MM patients, 3'U-tRFHisGTG loss depicted the association with bone disease (p=0.049). Furthermore, survival analysis revealed that loss of 3'U-tRFHisGTG was associated with significantly poor overall survival following treatment (p=0.018) and higher risk for short-term disease progression (p=0.036). Additionally, univariate Cox regression analysis strengthened both the inferior OS (HR: 2.375; p=0.022), and PFS (HR: 1.815; p=0.041) of MM patients with 3'U-tRFHisGTG loss. **Conclusions:** 3'U-tRFHisGTG loss in CD138+ cells of MM patients represent a novel molecular marker of unfavourable outcome, contributing to the improvement of personalized prognosis and patients' management.

Introduction: Autologous stem cell transplant (ASCT) remains standard of care for eligible patients with multiple myeloma (MM), but it is associated with variable outcomes that cannot be predicted by baseline risk factors. Here we investigate the composition and expression features of bone marrow aspirates collected from a cohort of patients treated with upfront ASCT and sufficiently long follow up at single cell resolution. **Methods:** To date, single cell RNA-Seq profiling (10X Genomics 5'v2 expression) has been performed on whole BM samples obtained 100 days following ASCT from 28 unique patients. Poor responders (PR; n=12) were defined as relapsing 2yr if not put on MT and >4yr if placed on MT (n=16). We compared these results with those obtained from whole BM or spleen samples collected from 67 Vk*MYC mice. Both sets of human and mice single cell data were processed with an additional reference-based clustering routine leveraging correlation with large, publicly available accession data from the ARCHS4 repository. **Results:** We have observed the expansion of tissue-specific C1q+ macrophages along with MM growth in untreated Vk*MYC BM (expressing C1qa/b/c and Fcgr4) and spleen (expressing C1qa/b/c, Apoe, and Selenop) suggesting that these C1q+ cells represent a tumor-associated macrophage (TAM) phenotype specific to MM. Similarly, in our post-ASCT human samples, we detected a small group of cells that overexpress C1QA/B/C, APOE, and SELENOP that are more highly represented in the PR. Globally, C1q+ TAMs in our Vk*MYC set are the highest expressers of Il18 suggesting a crucial pro-inflammatory function of these distinct cells. Neutrophils are highly involved in inflammatory response and demonstrate a gradient of maturation in Vk*MYC samples ranging from immature (expressing Camp and Ngp) to mature (expressing Il1b). Notably, some of the samples from GR were highly enriched for neutrophils that overexpressed markers of inhibition (PADI4, IRAK3, ANXA1) while those in the PR were up-regulated in pro-inflammatory markers such as FTH1. This result suggests that GR temper and control an inflammatory response directly post-ASCT while PR do not. **Conclusions:** This research suggests the involvement of an inflammatory microenvironment in disease progression post ASCT. In clinical practice, observing key modulations in the myeloid compartment following ASCT could serve as an early detection method for identifying patients likely to progress who could be candidates for clinical trials of anti-inflammatory therapy to delay MM progression.

Single-Cell profiling reveals aggressive tumor subcluster and compromised immune state in multiple myeloma

Hao Sun[1], Lixin Gong[1], Teng Fang[1], Zhen Yu[1], Lanting Liu[1], Tingyu Wang[1], Gang An[1], Lugui Qiu[1], Mu Hao[1]
[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin 300020, China

Introduction: Despite advancements in managing multiple myeloma (MM) patients, a subset of individuals still undergoes rapid disease progression and early death (ED) within two years of diagnosis. To gain insights into the disease and identify treatment targets, we examined the molecular characteristics of malignant and non-malignant cells in the bone marrow of MM patients with ED. **Methods:** We used single-cell RNA (scRNA) sequencing to analyze bone marrow aspirates from four MM patients with ED, eight without ED (nED), and seven healthy donors. Additionally, we incorporated CHIP-seq data to investigate epigenetic modifications. We constructed a comprehensive differentiation trajectory from stem cells to plasma cells and identified mutation hotspots using whole-exome sequencing. Non-malignant cell variations within the myeloma microenvironment were explored using pan-cancer references. The scRNA findings were validated through in vitro and in vivo experiments. **Results:** We classified Ig light chain-restricted tumor cells into ten subclusters and found that subcluster 4 had a higher presence in ED patients. Other subclusters grouped with the classical MM cells phenotype (CD38+CD19-CD56+/-CD24-). Subcluster 4 displayed a plasmablast phenotype (CD38+CD19+CD56+CD24+) with increased proliferation and drug resistance. Chromosomal aberrations and mutation hotspots were more prevalent in this subcluster. The genes specific to subcluster 4 were enriched in H3K27ac-mediated epigenetic regulation. We constructed a gene score, with LILRB4 showing high specificity for subcluster 4, effectively identifying ED patients. Combining this gene score with clinical factors improved patient stratification. In vitro and in vivo experiments confirmed the enhanced properties of LILRB4+ cells. The evolution trajectory of CD8+ T cells was divided into cell fate 1 (exhausted) and cell fate 2 (activated). Exhausted T cells were more abundant in ED patients and showed metabolic inhibition, reduced cell cycle activity, and upregulated apoptosis pathways. Memory T cell differentiation was impaired in the ED group, with increased expression of immunosuppressive genes like PIM3. In vitro experiments demonstrated that inhibiting PIM promoted memory T cell differentiation. Cell-cell interaction analysis revealed a significant increase in MM cell-CD14+ monocyte interactions in the ED group, particularly through LILRB4-interacting molecules. Co-culture experiments revealed that LILRB4+ MM cells promoted the differentiation of CD14+ monocytes into myeloid-derived suppressor cells. **Conclusions:** Our study provides insights into aggressive tumor subclusters and compromised immune states in MM patients with ED. We identified a unique population of LILRB4+ tumor cells and developed a gene score to identify ED patients. We also confirmed T cell dysfunction and highlighted the role of LILRB4+ tumor cells in immune evasion. Targeting LILRB4 could be a promising therapeutic strategy for MM treatment.

Memory T cell differentiation was impaired in the ED group, with increased expression of immunosuppressive genes like PIM3. In vitro experiments demonstrated that inhibiting PIM promoted memory T cell differentiation. Cell-cell interaction analysis revealed a significant increase in MM cell-CD14+ monocyte interactions in the ED group, particularly through LILRB4-interacting molecules. Co-culture experiments revealed that LILRB4+ MM cells promoted the differentiation of CD14+ monocytes into myeloid-derived suppressor cells. **Conclusions:** Our study provides insights into aggressive tumor subclusters and compromised immune states in MM patients with ED. We identified a unique population of LILRB4+ tumor cells and developed a gene score to identify ED patients. We also confirmed T cell dysfunction and highlighted the role of LILRB4+ tumor cells in immune evasion. Targeting LILRB4 could be a promising therapeutic strategy for MM treatment.

Profiling of patient bone marrow adipocytes in the myeloma microenvironment

Laura J. Trainor[1,2], Melissa D. Cantley[1,2], Cathal King[1,2], Natalya Plakhova[1], Mackenzie Skinner[1,2], Ryan Chai[3], Weng Hua Khoo[3], Peter Croucher[3], Kate Vandyke[1,2], Andrew Zannettino[1]

[1]University of Adelaide; [2]SAHMRI; [3]Garvan

Introduction: Bone marrow (BM) adipocytes (BMADs) make up 70% of the BM microenvironment and can promote multiple myeloma (MM) plasma cell proliferation and survival in vitro. The phenotypes of BMADs in MM and monoclonal gammopathy of undetermined significance (MGUS), and how BMADs support MM progression remain largely unknown. Here, we aimed to assess BMAD phenotype in differentiating and mature BMADs in BM samples from MGUS and MM patients and analyse their gene expression profile, to identify potential secreted factors which may play a role in supporting MMPC growth and survival. **Methods:** BMAD quantitation was conducted on CD138-stained trephines from age-matched controls (n=4), MGUS (n=9), and MM (n=14) patients via Osteomeasure and NDP.view2. Mesenchymal stromal cells (MSCs) isolated from control (n=7), MGUS (n=14), and MM (n=14) trephines were cultured in adipogenic media for 21 days, stained with Nile Red/DAPI and ImageJ used to quantitate BMAD number and lipid droplets/BMAD. For single cell RNA sequencing (scRNAseq) cells were enzymatically digested from 5 MM patient trephines (n=2 newly diagnosed, n=3 treated) and 1 control, viable GLYA- cells FACs sorted and scRNAseq conducted (10x Genomics Chromium V3.1). To identify novel microenvironmental factors that may interact with PCs, gene expression of secreted or cell surface ligands (ConnectomeDB2020) was assessed in sequenced cells, with cognate receptor expression in MM PCs confirmed in RNA sequencing data from 764 newly diagnosed MM patients (CoMMpass). Statistical analyses included Kruskal-Wallis, log-rank tests, and Pearson's correlation. **Results:** Histomorphometric analysis revealed MM patients with larger mean BMAD size (>2100um^2) had significantly poorer overall survival, compared with patients with smaller BMADs (median survival: 113.3 and 231.1 weeks; p=0.045, log-rank test). In vitro, there was two-fold reduction in BMAD number and 2.6-fold reduction in lipid droplets/BMAD in MM (p=0.0048), compared with MGUS. scRNAseq of 13683 BM cells, identified 81 mesenchymal lineage cells, characterised by CXCL12, FABP4, and SPP1 expression. 32% of the cluster were FABP4+ adipocyte-lineage cells, and uniquely expressed genes for 14 secreted or cell surface ligands, when compared with other MSC lineages. Furthermore, the receptor for 10/14 of these ligands were expressed by MMPCs in most of newly diagnosed MM patients, suggesting the potential for crosstalk between BMADs and MMPCs. **Conclusions:** Decreases in MM BMADs and lipid droplets demonstrated altered morphology and differentiation capacity in vitro, whilst histomorphometric analyses suggest association between BMAD phenotype and MM progression. For the first time, scRNAseq on MM trephines identified FABP4+ adipocyte-lineage cells express factors that directly interact with MMPCs. These findings help characterise BMADs as sources of MM-supportive factors, with further studies focussing on the identified factors and potential roles in MM progression.

Immunophenotypic profile defines cytogenetic stability and unveils distinct prognoses in patients with newly-diagnosed multiple myeloma (NDMM)

Wenqiang Yan[1], Lihui Shi[1], Jingyu Xu[1], Jian Cui[2], Yan Xu[1], Dehui Zou[1], Lugui Qiu[2], Gang An[2]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China; [2]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College

Introduction: The prognostic significance of multiple immune antigens in patients with newly-diagnosed multiple myeloma (NDMM) has been well established. However, there is still a knowledge gap regarding the intrinsic relationship between immunophenotypes and cytogenetic stability, as well as the identification of specific immunophenotypes for precise risk stratification across different disease stages. **Methods:** To address these unresolved issues, we conducted a study involving 1389 NDMM patients enrolled in the National Longitudinal Cohort of Hematological Diseases in China (NCT04645199). **Results:** Our results revealed the correlation between antigen expression and cytogenetics is more prominent compared to cytopenia or organ dysfunction. Most immune antigens, except CD38, CD138, and CD81, exhibit significant associations with the incidence of at least one cytogenetic abnormality. In turn, CD38-low, CD138-low, CD27-neg, and CD28-pos expressions were associated with inferior survival outcomes (P< 0.05). Through multivariate analysis, we identified CD138-low/CD27-neg as a specific aggressive immunophenotypic profile with the highest predictive value for poor prognosis. This profile remained an independent prognostic factor on progression-free survival (HR, 1.51; P=0.003) and overall survival (HR, 1.80; P< 0.001) even in the context of cytogenetics. Importantly, CD138-low/CD27-neg profile at relapse was also associated with inferior survival after the first relapse (P< 0.001). The antigen expression profiles were not strictly similar from diagnosis to relapse, especially CD138-low/CD27-neg pattern notably increased following disease progression (19.1% to 29.1%; P=0.005). **Conclusions:** In summary, we systematically described the comprehensive immunophenotypic landscapes of NDMM patients in a large observational cohort. Diverse immune profiles are strongly associated with various cytogenetic abnormalities but weakly correlated with cytopenia or organ dysfunction. Importantly, specific immunophenotypes (CD138-low/CD27-neg) could independently predict a high risk of progression or death regardless of disease stages and aggressive statuses.

SKY92 gene expression profiling and cytogenetics according to R2-ISS for multiple myeloma risk classification

Xiang Zhou[1], Benedict Engel[1], Annika Hofmann[1], Cornelia Vogt[1], Silvia Nerreter[1], Eva Teufel[1], Emilia Stanojkovska[1], Marietta Truger[2], Xianghui Xiao[1], Christine Riedhammer[1], Umair Munawar[1], Seungbin Han[1], Larissa Haertle[1], Claudia Haferlach[2], Hermann Einsele[3], Leo Rasche[1], Martin Kortüm[1]

[1]University Hospital Würzburg; [2]Munich Leukemia Lab; [3]Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany

Introduction: SKY92 gene expression profiling (GEP) has been developed to identify high-risk (HR) multiple myeloma (MM). This study aimed to evaluate the combination of SKY92 and cytogenetics according to R2-ISS (del(17p), t(4;14), 1q CNA) for HR detection in newly diagnosed (ND) and relapsed/refractory (RR) MM. **Methods:** We performed a single-center prospective study. Cytogenetics were analyzed on purified CD138 positive cells by FISH. SKY92 risk status was determined with MMprofiler gene expression assay. Whole genome sequencing (WGS) was performed to elucidate the discrepancy between the both risk stratification systems SKY92 and FISH. **Results:** Overall, 258 patients were included (NDMM: n=109; RRMM: n=149). SKY92 classification was available for 216 (83.7%) patients. Samples of 26 (17.7%) patients, who showed significantly lower bone marrow infiltration than the remaining patients (median: 20% vs 50%, P=0.006), did not meet the SKY92 quality control criteria. HR SKY92 was significantly enriched in RRMM (57/121, 47.1%) compared to NDMM (17/95, 17.9%) (P< 0.001). In RRMM, HR SKY92 was significantly more frequent in patients with ≥4 prior lines of therapies (32/52, 61.5%) than those with < 4 therapy lines (25/65, 36.2%) (P=0.009). Moreover, HR SKY92 was more common in patients who received high-dose melphalan and autologous stem cell transplant (48/89, 53.9%) than the remaining patients (9/32, 28.1%) (P=0.01). RRMM with HR SKY92 showed significantly shorter progression free survival (PFS) (P< 0.001) and overall survival (OS) (P< 0.001) than standard-risk (SR). In NDMM, HR SKY92 also indicated a significantly inferior PFS (P< 0.001) in comparison to SR. We then combined SKY92 with FISH according to R2-ISS in 181 patients (NDMM: n=79; RRMM: n=102). We found a discrepancy between the both risk stratification systems, with 67 (37.0%) and 99 (54.7%) patients being defined as HR by SKY92 and FISH, respectively. Overall, 13 (16.4%) NDMM and 36 (35.3%) RRMM patients showed HR in both SKY92 and FISH ("double-HR"). Double-HR presented a negative prognostic factor for PFS in both NDMM (P< 0.001) and RRMM (P< 0.0001). Furthermore, "double-HR" patients showed the worst OS (P< 0.001) in RRMM. To elucidate the discrepancy between FISH and SKY92, we performed WGS in 16 patients who exhibited either only HR SKY92 (n=7) or only HR FISH (n=9). Interestingly, 1 patient with bi-allelic TP53 inactivation (del + mut) and 6 patients with 1q CNA were determined as SR by SKY92 but as HR by FISH. Moreover, 4 out of 7 patients with only HR SKY92 but SR FISH displayed 1q CNA, which was detected only by WGS, and del1p32 was found in 1 patients. Of note, we found CRBN mutation in 3 out of 7 patients with only HR SKY92 but SR FISH. The remaining 2 patients did not show any known HR genomic alterations. **Conclusions:** We provide the first prospective evidence that "double-HR" (SKY92 + FISH according to R2-ISS) indicates the highest-risk MM.

Introduction: Our previous studies found that amino acids metabolism imbalance promotes multiple myeloma (MM) progression. We have revealed glycine was significantly increased in bone marrow (BM) microenvironment and blocking glycine utilization inhibits MM progression by disrupting glutathione balance. And excessive serine from the BM microenvironment impairs megakaryopoiesis and thrombopoiesis in MM. Moreover, with the kidney damage caused by the abnormal metabolism of amino acids, the excessive urea is accumulated and utilized by gut microbiota, and then results in nitrogen-recycling bacteria enrichment in MM. Our discoveries open new avenues for novel treatment strategies via intervention of amino acids intake in MM patients. However, the comprehensive metabolic profile and classification of MM is still lack. **Methods:** The BM and PB specimens were derived from health donors (nBM = 31; nPB = 31), newly diagnosed MM patients (nBM = 115; nPB = 115) and relapsed MM patients (nBM = 34; nPB = 34) with written consent from Xiangya Hospital, the Second Xiangya Hospital of CSU and the Blood Diseases Hospital of Chinese Academy of Medical Science & Peking Union Medical College. Plasma, sera and BM supernatants were extracted from these specimens and stored at −80 °C until analysis. Informed consent was obtained in accordance with the Declaration of Helsinki. **Results:** Identification of 6 metabolic subgroups in newly diagnosed MM based on PB metabolome. Based on the PB metabolome of MM patients, 6 metabolic subtypes were clustered (Type1, Type2, Type3, Type4, Type5, Type6), showing distinct metabolic profiles and clinical presentation. According to the metabolic characteristics, the subtypes were defined as amino acid & fatty acid (AA&FA) group, Carbohydrates (Carbs) group, Benzenoids (Ben) group, Carnitines & fatty acid (Carn & FA) group, Amino acid (AA) and short chain fatty acids (SCFA) group, respectively. Overall survival clinical characteristics differs in the 6 subgroups. To explore the difference

[1]Cancer Research Institute, School of Basic Medical Sciences, Central South University; [2]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin 300020, China.; [3]Xiangya Hospital, Central South University; [4]Department of Hematology, Xiangya Hospital, Central South University, Changsha, China.; [5]Hong Kong Baptist University; [6]State Key Laboratory of Experimental Hematology,Cancer Research Institute, School of Basic Medical Sciences, Central South University, Changsha, Hunan, China

Introduction: Our previous studies found that amino acids metabolism imbalance promotes multiple myeloma (MM) progression. We have revealed glycine was significantly increased in bone marrow (BM) microenvironment and blocking glycine utilization inhibits MM progression by disrupting glutathione balance. And excessive serine from the BM microenvironment impairs megakaryopoiesis and thrombopoiesis in MM. Moreover, with the kidney damage caused by the abnormal metabolism of amino acids, the excessive urea is accumulated and utilized by gut microbiota, and then results in nitrogen-recycling bacteria enrichment in MM. Our discoveries open new avenues for novel treatment strategies via intervention of amino acids intake in MM patients. However, the comprehensive metabolic profile and classification of MM is still lack. **Methods:** The BM and PB specimens were derived from health donors (nBM = 31; nPB = 31), newly diagnosed MM patients (nBM = 115; nPB = 115) and relapsed MM patients (nBM = 34; nPB = 34) with written consent from Xiangya Hospital, the Second Xiangya Hospital of CSU and the Blood Diseases Hospital of Chinese Academy of Medical Science & Peking Union Medical College. Plasma, sera and BM supernatants were extracted from these specimens and stored at −80 °C until analysis. Informed consent was obtained in accordance with the Declaration of Helsinki. **Results:** Identification of 6 metabolic subgroups in newly diagnosed MM based on PB metabolome. Based on the PB metabolome of MM patients, 6 metabolic subtypes were clustered (Type1, Type2, Type3, Type4, Type5, Type6), showing distinct metabolic profiles and clinical presentation. According to the metabolic characteristics, the subtypes were defined as amino acid & fatty acid (AA&FA) group, Carbohydrates (Carbs) group, Benzenoids (Ben) group, Carnitines & fatty acid (Carn & FA) group, Amino acid (AA) and short chain fatty acids (SCFA) group, respectively. Overall survival clinical characteristics differs in the 6 subgroups. To explore the difference

between the 6 subgroups, overall survival analysis reveals that MM patients in Carn & FA group and SCFA group presented better prognosis due to rich unsaturated fatty acids. Meanwhile, MM patients in Ben group and AA group presented poor prognosis. In addition, the plasma cell ratio in BM, secretion of immunoglobulin and β-microglobulin in serum were decreased in the Carn & FA group and SCFA group, meanwhile, the hemoglobin contents in serum were increased in the group. In contrast, MM patients in the AA group presented the malignant characteristics, which suggests amino acids rather than fatty acids correlates to malignant progression of MM. **Conclusions:** This study highlights, for the first time, the metabolic heterogeneity in MM patients and preliminary analysis on metabolic subtypes, which would play an active role in improving the current MM-stratification systems, and suggest that blocking amino acids may be an effective therapeutic intervention strategy.

Demographics, clinical features and treatment outcomes of waldenstrom macroglobulinemia from a tertiary care cancer centre in India

Bhausaheb Bagal[1], Lingaraj Nayak[1], Hasmukh Jain[1], Saswata Saha[2], Alok Shetty[1], Prashant Tembhare[3], Nikhil Patkar[2], Dhanlaxmi Shetty[2], Manju Sengar[1]

[1]Department of Medical Oncology, Tata Memorial Centre; [2]Tata Memorial Hospital; [3]Department of Hemato-pathology, ACTREC, Tata Memorial Centre

Introduction: Waldenstrom macroglobulinemia (WM) is a rare lymphoproliferative disorder that usually follows an indolent course. There is scarcity of data from Indian patients and available data suggest an early age of presentation, diagnosis with heavy disease burden. **Methods:** All consecutive patients diagnosed with WM between January 2013 and December 2022 were included in this analysis. The progression free survival (PFS) was calculated from date of treatment to disease progression or death and overall survival (OS) was defined as the duration from the diagnosis of WM to the date of death or last follow-up. **Results:** Seventy two patients were enrolled in this analysis and 57 patients were male (79 %) with a median age of 60 years (range 28-79 years). Most common presenting symptom was anaemia in 53 (74%), 4 had hemolytic anaemia, 13 out of 26 patients who had iron studies available showed concomitant iron deficiency anaemia and 4 of 44 patients tested had either vit B12 or folic acid deficiency. Symptoms of hyperviscosity were recorded in 21 (29%) patients out of which 5 patients underwent plasmapheresis. Symptom duration ranged from less than 1 month to 18 months with a median time of 4 months before diagnosis. The median haemoglobin at presentation was 7.3 gm/dl (range 3.9 -13.6) and median M band concentration was 3 gm/dl (range 0.1-10.5). Lymphadenopathy was recorded in 21 (27%) patients while splenomegaly was present in 23 (32%) patients. The International Prognostic Scoring System for WM (IPSSWM) at diagnosis was available for 57 patients with 29 (40%) in intermediate risk group and 27 (37.5%) in high risk group while only one patient in low risk group. Thirty seven patients had undergone MYD88 testing, out of which 31 (83%) patients were tested positive for MYD88 L265P mutation. Bendamustin-Rituximab was the most commonly used regimen followed by Bortezomib-Dexamethasome-Rituxima (BDR) in 33 (45%) and 22 (30%) respectively. Median lines of therapy received was one range (range 1-4) with second-line therapies administered to 15 (21%) patients while third or more lines were administered only in 4 (5%) patients. Over a median follow up period of 62 months, 28 patients have progressed with a median PFS of 5.4 months and 2 year and 5 years PFS of 80 and 62% respectively. Twenty patients have died with an estimated median OS of 12 years and 2 years and 5 year OS of 87 % and 70 % respectively. None of the variables tested including IPSS-WM scores, therapy received and MYD88 mutation status were significantly associated with PFS and OS. **Conclusions:** Despite the younger age of presentation most patients presented late with symptoms and intermediate or high risk IPSS-WM scores. Anaemia is the most common presentation with nutritional deficiencies/defective iron metabolism contributing in a significant number of patients. BR and BDR are two most commonly used regimens that result in comparable outcomes.

P-420

Unusual presentations of amyloidosis: a multicase analysis highlighting diverse clinical manifestations and diagnostic challenges

Ashwathy Balachandran Pillai[1], Melody Becnel[1]

[1]University of Texas MD Anderson Cancer Care Center

Introduction: Amyloidosis is a rare disorder characterized by extracellular deposition of abnormal protein fibrils in various organs. Light chain amyloidosis (AL) can be primary or secondary to lymphoproliferative disorders like multiple myeloma. We aim to provide detailed insights into the diverse clinical presentations and diagnostic challenges encountered in patients with AL. **Methods:** We conducted a retrospective analysis of four cases of AL, focusing on their unique clinical features, diagnostic evaluations, and treatment approaches. **Results:** 1: 54 yo F with recent COVID-19, presented with weakness, muscle stiffness, dyspnea, anemia& hypercalcemia. Imaging revealed lytic lesions, later diagnostics confirmed IgD kappa multiple myeloma. She developed dysphagia, dysphonia, cough, and dysphonia. Evaluation confirmed secondary AL with nerve, vocal cord, and muscle involvement. Treated with daratumumab, carfilzomib, lenalidomide & dexamethasone, followed ASCT using melphalan. Restaging assessments showed a significant reduction in osseous lesions and hematologic complete remission. Speech pathology evaluation and treatment of MM improved her symptoms noted above. 2: 48 yo F presented with intermittent vocal dysphonia felt to be due to vocal cord cyst. Excisional biopsy noted low-grade B-cell lymphoma with AL deposition. PET-CT revealed laryngeal uptake due to lymphoma. CT noted an enhancing ulcerated lesion on the right false cord. No evidence of systemic amyloid. No other treatment in the absence of any other lymphoid tissue involvement or symptoms. No evidence of recurrence or systemic AL. 3: 59 yo male presented with dysphonia following a respiratory infection that failed to improve despite steroids and H2 blockers. Laryngeal videostroboscopy noted an irregular and vascular lesion of vocal

between the 6 subgroups, overall survival analysis reveals that MM patients in Carn & FA group and SCFA group presented better prognosis due to rich unsaturated fatty acids. Meanwhile, MM patients in Ben group and AA group presented poor prognosis. In addition, the plasma cell ratio in BM, secretion of immunoglobulin and β-microglobulin in serum were decreased in the Carn & FA group and SCFA group, meanwhile, the hemoglobin contents in serum were increased in the group. In contrast, MM patients in the AA group presented the malignant characteristics, which suggests amino acids rather than fatty acids correlates to malignant progression of MM. **Conclusions:** This study highlights, for the first time, the metabolic heterogeneity in MM patients and preliminary analysis on metabolic subtypes, which would play an active role in improving the current MM-stratification systems, and suggest that blocking amino acids may be an effective therapeutic intervention strategy.

Demographics, clinical features and treatment outcomes of waldenstrom macroglobulinemia from a tertiary care cancer centre in India

Bhausaheb Bagal[1], Lingaraj Nayak[1], Hasmukh Jain[1], Saswata Saha[2], Alok Shetty[1], Prashant Tembhare[3], Nikhil Patkar[2], Dhanlaxmi Shetty[2], Manju Sengar[1]

[1]Department of Medical Oncology, Tata Memorial Centre; [2]Tata Memorial Hospital; [3]Department of Hemato-pathology, ACTREC, Tata Memorial Centre

Introduction: Waldenstrom macroglobulinemia (WM) is a rare lymphoproliferative disorder that usually follows an indolent course. There is scarcity of data from Indian patients and available data suggest an early age of presentation, diagnosis with heavy disease burden. **Methods:** All consecutive patients diagnosed with WM between January 2013 and December 2022 were included in this analysis. The progression free survival (PFS) was calculated from date of treatment to disease progression or death and overall survival (OS) was defined as the duration from the diagnosis of WM to the date of death or last follow-up. **Results:** Seventy two patients were enrolled in this analysis and 57 patients were male (79 %) with a median age of 60 years (range 28-79 years). Most common presenting symptom was anaemia in 53 (74%), 4 had hemolytic anaemia, 13 out of 26 patients who had iron studies available showed concomitant iron deficiency anaemia and 4 of 44 patients tested had either vit B12 or folic acid deficiency. Symptoms of hyperviscosity were recorded in 21 (29%) patients out of which 5 patients underwent plasmapheresis. Symptom duration ranged from less than 1 month to 18 months with a median time of 4 months before diagnosis. The median haemoglobin at presentation was 7.3 gm/dl (range 3.9 -13.6) and median M band concentration was 3 gm/dl (range 0.1-10.5). Lymphadenopathy was recorded in 21 (27%) patients while splenomegaly was present in 23 (32%) patients. The International Prognostic Scoring System for WM (IPSSWM) at diagnosis was available for 57 patients with 29 (40%) in intermediate risk group and 27 (37.5%) in high risk group while only one patient in low risk group. Thirty seven patients had undergone MYD88 testing, out of which 31 (83%) patients were tested positive for MYD88 L265P mutation. Bendamustin-Rituximab was the most commonly used regimen followed by Bortezomib-Dexamethasome-Rituxima (BDR) in 33 (45%) and 22 (30%) respectively. Median lines of therapy received was one range (range 1-4) with second-line therapies administered to 15 (21%) patients while third or more lines were administered only in 4 (5%) patients. Over a median follow up period of 62 months, 28 patients have progressed with a median PFS of 5.4 months and 2 year and 5 years PFS of 80 and 62% respectively. Twenty patients have died with an estimated median OS of 12 years and 2 years and 5 year OS of 87 % and 70 % respectively. None of the variables tested including IPSS-WM scores, therapy received and MYD88 mutation status were significantly associated with PFS and OS. **Conclusions:** Despite the younger age of presentation most patients presented late with symptoms and intermediate or high risk IPSS-WM scores. Anaemia is the most common presentation with nutritional deficiencies/defective iron metabolism contributing in a significant number of patients. BR and BDR are two most commonly used regimens that result in comparable outcomes.

Unusual presentations of amyloidosis: a multicase analysis highlighting diverse clinical manifestations and diagnostic challenges

Ashwathy Balachandran Pillai[1], Melody Becnel[1]

[1]University of Texas MD Anderson Cancer Care Center

Introduction: Amyloidosis is a rare disorder characterized by extracellular deposition of abnormal protein fibrils in various organs. Light chain amyloidosis (AL) can be primary or secondary to lymphoproliferative disorders like multiple myeloma. We aim to provide detailed insights into the diverse clinical presentations and diagnostic challenges encountered in patients with AL. **Methods:** We conducted a retrospective analysis of four cases of AL, focusing on their unique clinical features, diagnostic evaluations, and treatment approaches. **Results:** 1: 54 yo F with recent COVID-19, presented with weakness, muscle stiffness, dyspnea, anemia& hypercalcemia. Imaging revealed lytic lesions, later diagnostics confirmed IgD kappa multiple myeloma. She developed dysphagia, dysphonia, cough, and dysphonia. Evaluation confirmed secondary AL with nerve, vocal cord, and muscle involvement. Treated with daratumumab, carfilzomib, lenalidomide & dexamethasone, followed ASCT using melphalan. Restaging assessments showed a significant reduction in osseous lesions and hematologic complete remission. Speech pathology evaluation and treatment of MM improved her symptoms noted above. 2: 48 yo F presented with intermittent vocal dysphonia felt to be due to vocal cord cyst. Excisional biopsy noted low-grade B-cell lymphoma with AL deposition. PET-CT revealed laryngeal uptake due to lymphoma. CT noted an enhancing ulcerated lesion on the right false cord. No evidence of systemic amyloid. No other treatment in the absence of any other lymphoid tissue involvement or symptoms. No evidence of recurrence or systemic AL. 3: 59 yo male presented with dysphonia following a respiratory infection that failed to improve despite steroids and H2 blockers. Evaluation confirmed secondary AL with nerve, vocal cord, and muscle involvement. Treated with daratumumab, carfilzomib, lenalidomide & dexamethasone, followed ASCT using melphalan. Restaging assessments showed a significant reduction in osseous lesions and hematologic complete remission. Speech pathology evaluation and treatment of MM improved her symptoms noted above. 2: 48 yo F presented with intermittent vocal dysphonia felt to be due to vocal cord cyst. Excisional biopsy noted low-grade B-cell lymphoma with AL deposition. PET-CT revealed laryngeal uptake due to lymphoma. CT noted an enhancing ulcerated lesion on the right false cord. No evidence of systemic amyloid. No other treatment in the absence of any other lymphoid tissue involvement or symptoms. No evidence of recurrence or systemic AL. 3: 59 yo male presented with dysphonia following a respiratory infection that failed to improve despite steroids and H2 blockers. Laryngeal videostroboscopy noted an irregular and vascular lesion of vocal

fold submucosal, involving the posterior glottis and subglottis. He underwent direct micro laryngoscopy with CO2 laser excision of the lesions. Excisional biopsy confirmed AL. Workup negative for systemic involvement. He underwent focal radiation treatment. He is currently doing well with minimal change in voice quality and no evidence of recurrence. 4: A 59 yo F with chronic cough found to have a lesion on the posterior pharyngeal wall, which enlarged post-COVID infection. Initially felt to be benign and observed. However, the lesion later enlarged, and new nasopharyngeal and arytenoid lesions developed. Biopsy confirmed AL. She underwent transoral robotic surgery (TORS) resection of the lesions. No evidence of systemic AL or MM **Conclusions:** This multicase analysis highlights the diverse clinical presentations of AL as primary and secondary presentations. These cases underscore the diagnostic challenges faced in identifying amyloidosis and the importance of multidisciplinary collaboration in accurate diagnosis and appropriate management. Timely recognition and comprehensive evaluation are crucial for ruling out systemic involvement and ensuring optimal patient outcomes.

P-421

Reference interval of free light chain ratio for patients in chronic hemodialysis

Pablo Bustamante[1], Ricardo Valjalo[1], Alexis Bondi[1], Marco Alvarez[1], Ramón Perez[1], Viviana Balboa[1], Camila Peña[1]

[1]Hospital del Salvador, Santiago de Chile

Introduction: In patients with chronic kidney disease (CKD), the concentration of serum free light chains (FLC) increases proportionally to the degree of reduction in glomerular filtration rate (GFR). The currently used reference range of the FLC ratio (FLCr) Kappa/Lambda (K/L) in patients with CKD is between 0.37 and 3.1. Nevertheless, the normal range of FLCr in patients in hemodialysis (HD) is unclear. Recently, Long et al reported new FLCr ranges according to CKD stage, based on estimated GFR. However, this study considered only a few patients on HD. **Methods:** This is an observational and analytical cohort study. Patients on HD from a single HD center were included. They had more than 3 months of permanence on conventional HD, 3 times a week, with a high-flux membrane (Helixone®). K and L FLC determinations were performed using the Freelite® assay according to the Laboratory's instructions (Binding Site, Birmingham, UK). We determined K and L values, and the K/L ratio. These results were correlated with age and residual kidney function (RKF), defined as residual diuresis ≥250mL/day. 95% reference intervals values were calculated according to the recommendations of The Clinical and Laboratory Standards Institute (CLSI EP28-A3c). Atypical data (outliers) were evaluated with Tukey's test, and not removed from the analysis. Normality was evaluated with the D'agostino Pearson test. For monoclonal gammopathy (MG) detection, we performed capillary sPEP and FLC to all patients. In patients with monoclonal spike, hypogammaglobulinemia or altered FLCr, immunosubtraction (Sebia) was also performed. Analysis was made with Software Medcalc v20.104 and SPSS. The protocol was approved by the local Institutional Review Board. **Results:** A total of 138 patients were studied, since 5 patients with MG incidentally detected were excluded (2 MM, 3 MGUS). K showed a non-parametric distribution, with a mean of 162.24 mg/L (64.46 - 281.76 mg/L). L also showed a non-parametric distribution, with a mean of 149.87mg/L (47.15 - 312.58 mg/L). The reference range of FLCr showed a parametric distribution of 0.54 to 1.75. Both K and L increases with age until the 9th decade when they tend to decrease. Twenty-four percent of the patients still presented RKF. The results in both groups (with vs without RKF, respectively) were for K 128.69 +/- 51.4 mg/L vs 174.48 +/- 52.19 mg/L (p< 0.01); For Lambda 111.30 +/- 60.11 mg/L vs 163.82 +/- 58.32mg/L (p< 0.01). Regarding the K/L ratio, in patients with RKF was 1.24 +/- 0.32, while in patients without RKF was 1.12 +/- 0.30 (p< 0.04). **Conclusions:** To our knowledge, this is the largest study that attempts to define the reference interval of FLCr in stable patients on chronic HD. The K/L ratio in this population was 0.54 - 1.75, closer to that of patients without CKD. We hypothesize that this is due to the clearance of middle molecules by the high-flux membranes. The ratio and FLC levels are influenced by the RKF.

Impact of early response and CXCR4 mutation status on progression-free survival with ibrutinib-based therapy in Waldenström macroglobulinemia: a post hoc analysis of the iNNOVATE trial

Jorge Castillo[1], Shayna Sarosiek[1], Andrew Branagan[2], Alex Bokun[3], Hillary Peltier[4], Vincent Girardi[4], Michelle Pacia[4], Steven Treon[1]

[1]Dana-Farber Cancer Institute; [2]Massachusetts General Hospital; [3]Janssen Scientific Affairs, LLC; [4]Pharmacyclics LLC

Introduction: Ibrutinib is a Bruton tyrosine kinase inhibitor approved for adults with Waldenström macroglobulinemia (WM). In iNNOVATE (NCT02165397), a randomized, double-blind, phase 3 study, ibrutinib plus rituximab (I+R) was associated with greater progression-free survival (PFS) benefits compared with rituximab plus placebo (Buske C et al. J Clin Oncol. 2021). In patients with WM, achieving a partial response (PR) or better at 6 months with single-agent ibrutinib was prognostic of better PFS (Castillo JJ et al. Br J Haematol. 2021), and CXCR4 mutations were prognostic of inferior PFS (Castillo JJ et al. Blood Adv. 2022). This post hoc analysis of iNNOVATE assessed whether achievement of PR or very good PR (VGPR) by month 6 or 12 of I+R treatment was associated with a higher PFS rate. The role of CXCR4 mutation at baseline in predicting PFS with I+R was also assessed. **Methods:** We used landmark analysis to assess the probability of achieving PFS at ≤42 months in patients treated with I+R according to achievement of PR or VGPR at 6 (n=68) or 12 (n=64) months and according to CXCR4 mutation status at baseline (n=69). Hazard ratios were estimated using an unstratified Cox regression model with the response at 6 or 12 months or CXCR4 mutation status as covariates. P values were calculated using an unstratified log-rank test. **Results:** Patients who achieved PR or better at 6 months

fold submucosal, involving the posterior glottis and subglottis. He underwent direct micro laryngoscopy with CO2 laser excision of the lesions. Excisional biopsy confirmed AL. Workup negative for systemic involvement. He underwent focal radiation treatment. He is currently doing well with minimal change in voice quality and no evidence of recurrence. 4: A 59 yo F with chronic cough found to have a lesion on the posterior pharyngeal wall, which enlarged post-COVID infection. Initially felt to be benign and observed. However, the lesion later enlarged, and new nasopharyngeal and arytenoid lesions developed. Biopsy confirmed AL. She underwent transoral robotic surgery (TORS) resection of the lesions. No evidence of systemic AL or MM **Conclusions:** This multicase analysis highlights the diverse clinical presentations of AL as primary and secondary presentations. These cases underscore the diagnostic challenges faced in identifying amyloidosis and the importance of multidisciplinary collaboration in accurate diagnosis and appropriate management. Timely recognition and comprehensive evaluation are crucial for ruling out systemic involvement and ensuring optimal patient outcomes.

Impact of early response and CXCR4 mutation status on progression-free survival with ibrutinib-based therapy in Waldenström macroglobulinemia: a post hoc analysis of the iNNOVATE trial

Jorge Castillo[1], Shayna Sarosiek[1], Andrew Branagan[2], Alex Bokun[3], Hillary Peltier[4], Vincent Girardi[4], Michelle Pacia[4], Steven Treon[1]

[1]Dana-Farber Cancer Institute; [2]Massachusetts General Hospital; [3]Janssen Scientific Affairs, LLC; [4]Pharmacyclics LLC

Introduction: Ibrutinib is a Bruton tyrosine kinase inhibitor approved for adults with Waldenström macroglobulinemia (WM). In iNNOVATE (NCT02165397), a randomized, double-blind, phase 3 study, ibrutinib plus rituximab (I+R) was associated with greater progression-free survival (PFS) benefits compared with rituximab plus placebo (Buske C et al. J Clin Oncol. 2021). In patients with WM, achieving a partial response (PR) or better at 6 months with single-agent ibrutinib was prognostic of better PFS (Castillo JJ et al. Br J Haematol. 2021), and CXCR4 mutations were prognostic of inferior PFS (Castillo JJ et al. Blood Adv. 2022). This post hoc analysis of iNNOVATE assessed whether achievement of PR or very good PR (VGPR) by month 6 or 12 of I+R treatment was associated with a higher PFS rate. The role of CXCR4 mutation at baseline in predicting PFS with I+R was also assessed. **Methods:** We used landmark analysis to assess the probability of achieving PFS at ≤42 months in patients treated with I+R according to achievement of PR or VGPR at 6 (n=68) or 12 (n=64) months and according to CXCR4 mutation status at baseline (n=69). Hazard ratios were estimated using an unstratified Cox regression model with the response at 6 or 12 months or CXCR4 mutation status as covariates. P values were calculated using an unstratified log-rank test. **Results:** Patients who achieved PR or better at 6 months

(n=39) had a higher PFS rate at 42 months than patients who did not (n=29) (78% [95% CI 60-88%] vs 68% [95% CI 48-82%]), but the difference over the entire study period was not significant (P=0.41). The difference was significant over the study period between patients who did (n=49) and did not achieve PR (n=15) at 12 months (P=0.027), with 42-month PFS rates of 80% (95% CI 63-90%) and 60% (95% CI 32-80%), respectively. For patients who achieved VGPR or better at 6 months (n=9) versus those who did not (n=59), the 42-month PFS rates were 86% (95% CI 33-98%) versus 72% (95% CI 58-82%), with overall P=0.19. The corresponding values for patients with (n=13) and without VGPR (n=51) at 12 months were 82% (95% CI 45-95%) and 74% (95% CI 57-85%); overall P=0.36. For patients with CXCR4 mutation at baseline (n=26) versus those without mutation (n=43), the PFS rates at 42 months were 63% (95% CI 40-79%) versus 85% (95% CI 70-93%), respectively (overall P=0.39). **Conclusions:** Patients treated with I+R maintained durable remission irrespective of CXCR4 mutational status or attainment of PR or VGPR at 6 or 12 months. A trend towards greater PFS benefits of I+R at 42 months was seen in patients who achieved PR or VGPR at months 6 or 12 and those without CXCR4 mutations. The findings are consistent with single-agent ibrutinib data (Castillo JJ et al. Br J Haematol. 2021), which showed a greater PFS rate in patients who achieved PR or better at 6 months and those who did not have CXCR4 mutations. The analysis is limited by a small sample size. The iNNOVATE study was funded by Pharmacyclics, LLC, an AbbVie company.

Partial response or better at 6 months is not a prognostic indicator of progression-free survival in Waldenström macroglobulinemia treated with zanubrutinib: a post hoc analysis of the ASPEN study

Jorge Castillo[1], Alessandra Tedeschi[2], Constantine Tam[3,4], Christian Buske[5], Roger Owen[6], Veronique Leblond[7], Stephen Opat[4], Andrew Branagan[8], Shayna Sarosiek[1], Gottfried von Keudell[9], Steven Treon[1], Heather Allewelt[10], Wai Chan[10], Jingjing Schneider[10], Meletios Dimopoulos[11]

[1]Dana-Farber Cancer Institute; [2]Great Metropolitan Hospital Niguarda, Piazza Ospedale; [3]The Alfred Hospital; [4]Monash University; [5]Institute of Experimental Cancer Research, CCCU, University Hospital Ulm; [6]St. James's University Hospital; [7]Sorbonne University, Pitié Salpêtrière Hospital; [8]Massachusetts General Hospital; [9]Beth Israel Deaconess Medical Center; [10]BeiGene (Beijing) Co, Ltd. and BeiGene USA, Inc.; [11]National and Kapodistrian University of Athens

Introduction: Attaining partial response (PR) or better at 6 months was associated with superior progression-free survival (PFS) in patients (pts) with Waldenström macroglobulinemia (WM) treated with ibrutinib (IBR) monotherapy (Castillo et al. Br J Haematol. 2021); it could be a surrogate for PFS in prospective clinical trials evaluating Bruton tyrosine kinase inhibitors (BTKis) in pts with WM. This post hoc analysis of the ASPEN study aimed to evaluate the PFS prognostic value of attaining PR or better at 6 months in pts with WM treated with zanubrutinib (ZANU), a second-generation BTKi with more selectivity and sustained BTKi occupancy than IBR. The PFS prognostic value of very good partial response (VGPR) or better at 12 months was also evaluated. **Methods:** The methodology for the ASPEN study has been described previously (Tam et al. Blood. 2020). This post hoc analysis evaluated the attainment of PR or better at 6 months and VGPR at 12 months from therapy initiation. Responses were assessed based on criteria from the 11th International Workshop on Waldenstrom's macroglobulinemia (Treon et al. Semin Hematol. 2023). PFS was estimated starting at the 6-month mark in pts with response assessment at 6 months and the 12-month mark in pts with response assessment at 12 months. Since 2 analyses were done using the same dataset, P values <.025 were considered statistically significant. **Results:** In the IBR arm, response data at 6 months were available for 86 pts, of whom 57 (66%) attained PR or better. PR or better at 6 months was associated with favorable PFS in pts with WM treated with IBR (hazard ratio [HR], 0.47; 95% CI, 0.21-1.06; P=.0697). In the ZANU arm, response data at 6 months were available for 93 pts, of whom 67 (72%) attained PR or better. The PFS in pts with WM treated with ZANU was similar between those who did and did not attain PR or better at 6 months (HR, 1.53; 95% CI, 0.43-5.41; P=.5113). The 3-year landmark PFS event-free rates from the 6-month mark with ZANU (attained PR at 6 months, 81%; did not attain PR at 6 months, 87%) were consistently similar to those in IBR-treated pts with PR or better at 6 months (80%). In contrast, the event-free rate was lower (65%) in pts treated with IBR who did not attain PR or better at 6 months. In the IBR arm, response data at 12 months were available for 81 pts, of whom 11 (14%) attained VGPR or better. In the ZANU arm, response data at 12 months were available for 85 pts, of whom 22 (26%) attained VGPR or better. Pts treated with IBR (HR, 0.77; 95% CI, 0.18-3.32; P=.7225) or ZANU (HR, 0.86; 95% CI, 0.24-3.14; P=.8248) had similar PFS rates regardless of whether they attained VGPR or better at 12 months. **Conclusions:** Results of the ASPEN trial provide additional support for PR or better at 6 months as a positive prognostic factor for PFS in pts with WM treated with IBR. PFS in ZANU-treated pts, whether or not they attained PR or better at 6 months, was similar to PFS in IBR-treated pts with PR or better at 6 months.

Partial response or better at 6 months is not shown to be a prognostic indicator of progression-free survival in Waldenström macroglobulinemia treated with acalabrutinib: a post hoc analysis

Jorge Castillo[1], Shayna Sarosiek[1], Andrew Branagan[2], Gottfried von Keudell[3], Bob Shaw[4], Steven Treon[1]

[1]Dana-Farber Cancer Institute; [2]Massachusetts General Hospital; [3]Beth Israel Deaconess Medical Center; [4]AstraZeneca

Introduction: Attaining partial response (PR) or better at 6 months was associated with superior progression-free survival (PFS) in patients (pts) with Waldenström macroglobulinemia (WM) treated with ibrutinib (IBR) monotherapy (Castillo et al. Br

J Haematol 2020); it could be a surrogate for PFS in prospective clinical trials evaluating Bruton tyrosine kinase inhibitors in WM. This post hoc analysis assessed the PFS prognostic value of attaining PR or better at 6 and 12 months in participants with WM treated with acalabrutinib, a second-generation BTK inhibitor. **Methods:** The methodology for the phase II study of acalabrutinib in WM has been described previously (Owen et al. Lancet Haematol 2020). This post hoc analysis evaluated the attainment of PR or better at 6 months and 12 months from therapy initiation. Responses were assessed based on criteria from the 11th International Workshop for WM (Treon et al. Semin Hematol 2023). PFS was estimated starting at the 6-month mark for participants with response assessment at 6 months and the 12-month mark for participants with response assessment at 12 months. Participants who died, progressed, or were not assessed at the landmarks were excluded from the analysis. Since two analyses were performed in the same data set, P-values < 0.025 were considered statistically significant. **Results:** At 6 months, response data were available from 94 participants, of whom 60 (64%) attained a PR or better on acalabrutinib. The median PFS was 61.9 months (95% CI 55.7-not reached) in the group that attained a PR or better versus not reached (95% CI 35.6 months-not reached) in the group that did not. The hazard ratio (HR) was 0.70 (95% CI 0.35-1.40; p=0.31; Figure, left). At 12 months, response data were available from 87 participants, 59 (68%) attained a PR or better. The median PFS was not reached (95% CI 50.1-not reached) in the group that attained a PR or better versus not reached (95% CI 30.1 months-not reached) in the group that did not. The hazard ratio (HR) was 0.61 (95% CI 0.29-1.30; p=0.20; Figure, right). **Conclusions:** This post hoc analysis supports attaining PR or better at 6 months as a numerically, though not a statistically, positive prognostic factor for PFS in patients with WM treated with acalabrutinib. This analysis, however, is underpowered, given the sample size and immature follow-up.

Cardiac AL amyloidosis experienced in the last decade from a single center

Simge Erdem[1], Metban Guzel Mastanzade[1], Pelin Karaca Ozer[2], Okan Cetin[3], Ali Cem Hacialioglu[3], Mehmet Aydogan[2], Gulcin Yegen[4], Sengul Beyaz[2], Sevgi Kalayoglu-Besisik[1]

[1]Istanbul University Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Hematology; [2]Istanbul University Istanbul Faculty of Medicine, Department of Cardiology; [3]Istanbul University Istanbul Faculty of Medicine, Department of Internal Medicine; [4]Istanbul University Istanbul Faculty of Medicine, Department of Pathology; [5]Ankara City Hospital, Department of Immunology and Allergic Diseases

Introduction: Cardiac amyloidosis (CA) is rare and with poor prognosis. Light chain (AL) and transthyretin cardiac amyloidosis (ATTR) build up the main etiology. The presentation may be incidentally during different reasons evaluation or with signs and/or symptoms related to restrictive cardiomyopathy, heart failure, and /or conduction disease. In general, CA diagnosis is based on clinical suspicion and can be diagnosed noninvasively. Electrocardiogram (ECG), echocardiogram (ECHO), and cardiac magnetic resonance imaging (CMRI) are the often-used cardiac tests where the latter is less widely available. Early diagnosis of CA may modify the traditional poor biologic outcome in the era of the new drugs. Here we aimed to document the characteristics of CA cases as single-center experiences. **Methods:** The institutional ECHO Laboratory automated system was screened retrospectively with the keyword of CA. The clinical characteristics were obtained from institutional follow-up charts in the Hematology department. All CA suspected cases were evaluated among paraproteinemia and plasma cell disorder. ECG and in some cases, CMRI were complimentary. **Results:** A total of 77 cases of suspected AL cardiac amyloidosis were enrolled in the study. Male to female ratio was nearly equal. The mean age of male patients was a little older compared to females (65.7 and 61.3 years, respectively). The heart was the most involved organ (65%) followed by the kidney (49.4%) and bone marrow (45.5%). Low voltage on ECG was the commonest (32.5%) CA finding. Conduction abnormalities were not frequent (11.7%). The mean interventricular septum thickness was 1.51±0.31, and the left ventricular posterior wall thickness was 1.31±0.28 cm. Left ventricular ejection fraction was in general (88.3%) preserved. The diastolic dysfunction and granular pattern of the interventricular septum on ECHO were with a striking ratio of 76.6% and 64.9%, respectively. Diastolic dysfunction was in a restrictive filling pattern in 23.4% of the patients. The mean proBNP level was 6117.15 pg/ml and troponin-I 57.5 ng/ml. During the follow-up period, 37.7% of the patients died. In 37.9% of deaths, the cause was CA. **Conclusions:** We wished to document our results from the last decade when clinical trials and awareness studies in amyloidosis with new treatment modalities are emerging. In our study, the CA-related mortality rate was consistent with the literature, but we aimed with early recognition, new anti-plasma cell, and also anti-amyloid treatment providing to decrease this ratio.

Keywords: AL amyloidosis, cardiac amyloidosis.

Thrombotic and bleeding complications in patients with AL amyloidosis

Despina Fotiou[1], Sotiria Spiliopoulou[1], Foteini Theodorakakou[1], Maria Gavriatopoulou[1], Magdalini Migkou[1], Nikolaos Kanellias[2], Evangelos Eleutherakis-Papaiakovou[1], Panagiotis Malandrakis[1], Vassiliki Spiliopoulou[1], Ioanna Dialoupi[1], Ioannis Ntanasis-Stathopoulos[1], Evangelos Terpos[1], Meletios Dimopoulos[1], Efstathios Kastritis[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece; [2]London Northwest University Healthcare NHS trust

Introduction: Hemostatic abnormalities and deregulated coagulation are among the less well studied complications in AL amyloidosis linked to significant mortality and morbidity for patients with the disease. We describe thrombotic and hemorrhagic events in AL patients treated in the recent era to better understand

J Haematol 2020); it could be a surrogate for PFS in prospective clinical trials evaluating Bruton tyrosine kinase inhibitors in WM. This post hoc analysis assessed the PFS prognostic value of attaining PR or better at 6 and 12 months in participants with WM treated with acalabrutinib, a second-generation BTK inhibitor. **Methods:** The methodology for the phase II study of acalabrutinib in WM has been described previously (Owen et al. Lancet Haematol 2020). This post hoc analysis evaluated the attainment of PR or better at 6 months and 12 months from therapy initiation. Responses were assessed based on criteria from the 11th International Workshop for WM (Treon et al. Semin Hematol 2023). PFS was estimated starting at the 6-month mark for participants with response assessment at 6 months and the 12-month mark for participants with response assessment at 12 months. Participants who died, progressed, or were not assessed at the landmarks were excluded from the analysis. Since two analyses were performed in the same data set, P-values < 0.025 were considered statistically significant. **Results:** At 6 months, response data were available from 94 participants, of whom 60 (64%) attained a PR or better on acalabrutinib. The median PFS was 61.9 months (95% CI 55.7-not reached) in the group that attained a PR or better versus not reached (95% CI 35.6 months-not reached) in the group that did not. The hazard ratio (HR) was 0.70 (95% CI 0.35-1.40; p=0.31; Figure, left). At 12 months, response data were available from 87 participants, 59 (68%) attained a PR or better. The median PFS was not reached (95% CI 50.1-not reached) in the group that attained a PR or better versus not reached (95% CI 30.1 months-not reached) in the group that did not. The hazard ratio (HR) was 0.61 (95% CI 0.29-1.30; p=0.20; Figure, right). **Conclusions:** This post hoc analysis supports attaining PR or better at 6 months as a numerically, though not a statistically, positive prognostic factor for PFS in patients with WM treated with acalabrutinib. This analysis, however, is underpowered, given the sample size and immature follow-up.

Cardiac AL amyloidosis experienced in the last decade from a single center

Simge Erdem[1], Metban Guzel Mastanzade[1], Pelin Karaca Ozer[2], Okan Cetin[3], Ali Cem Hacialioglu[3], Mehmet Aydogan[2], Gulcin Yegen[4], Sengul Beyaz[2], Sevgi Kalayoglu-Besisik[1]

[1]Istanbul University Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Hematology; [2]Istanbul University Istanbul Faculty of Medicine, Department of Cardiology; [3]Istanbul University Istanbul Faculty of Medicine, Department of Internal Medicine; [4]Istanbul University Istanbul Faculty of Medicine, Department of Pathology; [5]Ankara City Hospital, Department of Immunology and Allergic Diseases

Introduction: Cardiac amyloidosis (CA) is rare and with poor prognosis. Light chain (AL) and transthyretin cardiac amyloidosis (ATTR) build up the main etiology. The presentation may be incidentally during different reasons evaluation or with signs and/or symptoms related to restrictive cardiomyopathy, heart failure, and /or conduction disease. In general, CA diagnosis is based on clinical suspicion and can be diagnosed noninvasively. Electrocardiogram (ECG), echocardiogram (ECHO), and cardiac magnetic resonance imaging (CMRI) are the often-used cardiac tests where the latter is less widely available. Early diagnosis of CA may modify the traditional poor biologic outcome in the era of the new drugs. Here we aimed to document the characteristics of CA cases as single-center experiences. **Methods:** The institutional ECHO Laboratory automated system was screened retrospectively with the keyword of CA. The clinical characteristics were obtained from institutional follow-up charts in the Hematology department. All CA suspected cases were evaluated among paraproteinemia and plasma cell disorder. ECG and in some cases, CMRI were complimentary. **Results:** A total of 77 cases of suspected AL cardiac amyloidosis were enrolled in the study. Male to female ratio was nearly equal. The mean age of male patients was a little older compared to females (65.7 and 61.3 years, respectively). The heart was the most involved organ (65%) followed by the kidney (49.4%) and bone marrow (45.5%). Low voltage on ECG was the commonest (32.5%) CA finding. Conduction abnormalities were not frequent (11.7%). The mean interventricular septum thickness was 1.51±0.31, and the left ventricular posterior wall thickness was 1.31±0.28 cm. Left ventricular ejection fraction was in general (88.3%) preserved. The diastolic dysfunction and granular pattern of the interventricular septum on ECHO were with a striking ratio of 76.6% and 64.9%, respectively. Diastolic dysfunction was in a restrictive filling pattern in 23.4% of the patients. The mean proBNP level was 6117.15 pg/ml and troponin-I 57.5 ng/ml. During the follow-up period, 37.7% of the patients died. In 37.9% of deaths, the cause was CA. **Conclusions:** We wished to document our results from the last decade when clinical trials and awareness studies in amyloidosis with new treatment modalities are emerging. In our study, the CA-related mortality rate was consistent with the literature, but we aimed with early recognition, new anti-plasma cell, and also anti-amyloid treatment providing to decrease this ratio.

Keywords: AL amyloidosis, cardiac amyloidosis.

Introduction: Hemostatic abnormalities and deregulated coagulation are among the less well studied complications in AL amyloidosis linked to significant mortality and morbidity for patients with the disease. We describe thrombotic and hemorrhagic events in AL patients treated in the recent era to better understand

J Haematol 2020); it could be a surrogate for PFS in prospective clinical trials evaluating Bruton tyrosine kinase inhibitors in WM. This post hoc analysis assessed the PFS prognostic value of attaining PR or better at 6 and 12 months in participants with WM treated with acalabrutinib, a second-generation BTK inhibitor. **Methods:** The methodology for the phase II study of acalabrutinib in WM has been described previously (Owen et al. Lancet Haematol 2020). This post hoc analysis evaluated the attainment of PR or better at 6 months and 12 months from therapy initiation. Responses were assessed based on criteria from the 11th International Workshop for WM (Treon et al. Semin Hematol 2023). PFS was estimated starting at the 6-month mark for participants with response assessment at 6 months and the 12-month mark for participants with response assessment at 12 months. Participants who died, progressed, or were not assessed at the landmarks were excluded from the analysis. Since two analyses were performed in the same data set, P-values < 0.025 were considered statistically significant. **Results:** At 6 months, response data were available from 94 participants, of whom 60 (64%) attained a PR or better on acalabrutinib. The median PFS was 61.9 months (95% CI 55.7-not reached) in the group that attained a PR or better versus not reached (95% CI 35.6 months-not reached) in the group that did not. The hazard ratio (HR) was 0.70 (95% CI 0.35-1.40; p=0.31; Figure, left). At 12 months, response data were available from 87 participants, 59 (68%) attained a PR or better. The median PFS was not reached (95% CI 50.1-not reached) in the group that attained a PR or better versus not reached (95% CI 30.1 months-not reached) in the group that did not. The hazard ratio (HR) was 0.61 (95% CI 0.29-1.30; p=0.20; Figure, right). **Conclusions:** This post hoc analysis supports attaining PR or better at 6 months as a numerically, though not a statistically, positive prognostic factor for PFS in patients with WM treated with acalabrutinib. This analysis, however, is underpowered, given the sample size and immature follow-up.

Thrombotic and bleeding complications in patients with AL amyloidosis

Despina Fotiou[1], Sotiria Spiliopoulou[1], Foteini Theodorakakou[1], Maria Gavriatopoulou[1], Magdalini Migkou[1], Nikolaos Kanellias[2], Evangelos Eleutherakis-Papaiakovou[1], Panagiotis Malandrakis[1], Vassiliki Spiliopoulou[1], Ioanna Dialoupi[1], Ioannis Ntanasis-Stathopoulos[1], Evangelos Terpos[1], Meletios Dimopoulos[1], Efstathios Kastritis[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece; [2]London Northwest University Healthcare NHS trust

Introduction: Hemostatic abnormalities and deregulated coagulation are among the less well studied complications in AL amyloidosis linked to significant mortality and morbidity for patients with the disease. We describe thrombotic and hemorrhagic events in AL patients treated in the recent era to better understand

the causes of deregulated coagulation. **Methods:** We analyzed the records of 450 patients treated in a single center to identify clinically relevant episodes of venous (VTE), arterial embolic events (AEE) and bleeding events. **Results:** Median age was 65 years (39-95) and 54% were male. The median follow-up was 55.3 months (95% CI 49.3-63.0). In 26 (5.8%) patients at least one VTE was recorded; deep vein thrombosis in 2.3%, pulmonary embolism in 2.4%, other in 1.1%. Eighteen patients were on anti-clonal treatment at the time of the event; 11 were on IMiDs-agent based therapy. Among patients with VTE, 36% were on antiplatelets and 52% on antithrombotic prophylaxis. AEE was reported in 22 (5%) of patients; stroke 2.9%, acute myocardial infarction 1.6%, other in 0.5%. Median time from diagnosis to VTE was 9.5 months (0.1 – 107 months) and to AEE 14 months (0.62-114 months). Lower albumin levels (p=0.040), lower eGFR (p=0.010), extensive bone marrow infiltration (0.010), soft tissue involvement (p=0.029), IMiD-based therapy (p=0.001) and history of prior thrombosis (≤0.001) were associated with VTE. A prior VTE history remained the only prognostic variable in the multivariate model (HR 9.3, p=0.001, 95% CI 2.36-36.6). Coronary arterial disease (p=0.045), prior AEE (p=0.041), higher 24hour urine protein (p=0.008) and higher platelet count at diagnosis (p=0.020) were associated with AEE risk. Cardiac involvement and Mayo stage were not risk factors for thrombotic events. Significant bleeding events were reported in 41 patients (9%) and were the cause of death in 8 (mortality 19%); CNS in 1.3%, GI in 4.6%, other in 3.1%. Median time from diagnosis to bleeding events was 1.7 months (0.1 to 166 months). Bleeding risk was higher in patients on antiplatelets (15% vs 7.4%, p=0.05) but not on antithrombotic therapy. Higher serum creatinine (p=0.040) and higher baseline vWFAg (p=0.001, n=112) were linked to bleeding. Using competing risk analysis (death due to any cause as competing event), the cumulative probability of thrombosis and bleeding at 6 months was 4.1% and 4.6% vs 14.5% for death, at 1 year 6% and 5.6% vs 23% for death, at 2 years 7% and 6.8% vs 29% for death, and at 5 years 10.8%, 9.8% and 41% respectively. **Conclusions:** Hemostatic complications associated with AL amyloidosis are common. Increased thrombotic risk and hemorrhagic diathesis or both, increase morbidity and mortality and make optimal management highly complex. Most events occur early but a constant risk remains present throughout the disease course. To optimize anticoagulation clinical risk factors need to be coupled to clotting parameter abnormalities in future studies.

Smoldering multiple myeloma associated with a acquired von Willebrand syndrome, successfully treated by daratumumab, lenalidomide and dexamethasone

Michael Iarossi[1], Marie-Christiane Madeleine Vekemans[2], Nicolas Weynants[3], Cédric Hermans[1]

[1]Saint Luc Hospital; [2]Department of Internal Medicine, Université Catholique de Louvain (UCLouvain), Brussels, Belgium; [3]Hôpital d'Arlon

Introduction: Acquired von Willebrand syndrome (AvWS) is a rare entity with approximately 700 cases described in the literature, probably underestimated due to a wide range of clinical features. The syndrome results from a quantitative or qualitative defect, with symptoms identical to the constitutional form of von Willebrand disease. Many etiologies are responsible for this condition, mainly lymphoproliferative and myeloproliferative syndromes, as well as cardiac diseases. Several mechanisms have been involved depending on the etiology. Monoclonal gammopathy is the leading cause of AvWS, the mechanism encountered in this case is the production of anti-von Willebrand factor antibodies, which may be specific and inactivate von Willebrand factor (VWF) or aspecific, resulting in rapid clearance of VWF. **Methods:** Here we report the case of a 84-year-old female, with no history of abnormal bleeding symptoms (spontaneous or provoked), regularly seen for recurrent digestive bleeds, requiring numerous blood transfusions (more than 25 transfusions in 4 years). A von Willebrand disease type 3 was confirmed with a von Willebrand factor antigen (vWF:Ag) at 3% (normal range, 50-120%), a activity of the cofactor of ristocetin (vWF:RCo) at 4% (normal range, 50-150%) and a coagulant activity of factor VIII (FVIII:C) at 4% (normal range, 50-150%). A complete work-up lead to the suspicion of an AvWS-SMM, with a monoclonal IgG kappa peak of 1.9g/L, and a bone marrow biopsy infiltrated by 15% plasma cells. **Results:** Treatment consists in either controlling spontaneous bleeding or preventing surgically induced bleeding on the one hand and treating the underlying pathology on the other. However, in patients with asymptomatic lymphoproliferative malignancies, this decision can be difficult to make because of the impact of these therapies on the patient's quality of life. First line options like DDAVP, IVIG treatment (in case of IgG peak) or VWF/FVIII concentrate should be proposed, but response are highly variable. Immunosuppressive agents such as rituximab, cyclophosphamide and azathioprine were ineffective in the majority of cases. When first line options are ineffective it is necessary to treat SMM. Treatment protocol is decided on a case-by-case basis, taking into account the benefit-risk ratio. Proteasome inhibitors and imide-based immunomodulatory drugs (IMiDs) can cause significant side effects, such as thrombocytopenia, and may require thromboprophylaxis that can complicate the management of such situations. Daratumumab is a human monoclonal antibody designed to specifically target the CD38 antigen expressed on plasma cells, approved for the treatment of multiple myeloma. **Conclusions:** After unsuccessful trials with DDAVP, IVIG, rituximab and the need for a chronic use of Wilate®, a combination of daratumumab, lenalidomide and dexamethasone was started with a favorable outcome after two cycles of treatment, with normalization of all coagulation parameters and by the absence of recurrent digestive bleeding.

the causes of deregulated coagulation. **Methods:** We analyzed the records of 450 patients treated in a single center to identify clinically relevant episodes of venous (VTE), arterial embolic events (AEE) and bleeding events. **Results:** Median age was 65 years (39-95) and 54% were male. Clinicopathological profile and treatment outcomes in patients with monoclonal gammopathy of renal significance (MGRS): a single centre experience

Aditya Jandial[1], Ritambhra Nada[2], Uday Yanamandra[3], Charanpreet Singh[1], Arihant Jain[2], Deepesh Lad[1], Gaurav Prakash[2], Alka Khadwal[2], Raja Ramachandran[2], Ritu Aggarwal[2], Sreejesh Sreedharanunni[1], Reena Das[2], Pankaj Malhotra[1]

[1]Department of Clinical Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh; [2]PGIMER Chandigarh; [3]Armed Forces Medical College

Introduction: Monoclonal gammopathy of renal significance (MGRS) refers to a heterogeneous group of disorders where abnormal monoclonal protein produced by a plasma cell or B-cell clone results in renal dysfunction. These are rare disorders and do not meet diagnostic criteria for other hematologic malignancies. There is limited literature on MGRS from India. **Methods:** We performed a retrospective analysis of MGRS patients treated at PGIMER Chandigarh from January 2013 to December 2022. All patients required confirmation of MGRS on renal biopsy for inclusion in the study. Patients with cast nephropathy and renal AL Amyloidosis were excluded. Hematologic response was defined as complete response (CR) if normalization of FLC was achieved. Very good partial response (VGPR) and partial response (PR) required 90% or 50% monoclonal protein reduction, respectively. Renal response was defined as >30% reduction of 24 h proteinuria (in the absence of renal progression). **Results:** A total of 31 MGRS patients were analyzed. The median age at diagnosis was 48 years (range 29 – 65 years); 45.2% were females. The median duration of symptoms was 6 months (range 1 – 24 months). Most common presenting complaints were fatigue (82.8%), pedal edema (64.5%), and frothuria (32.2%). At presentation, 20 patients (64.5%) had eGFR 1 renal lesion on kidney biopsy. Most patients (n = 27; 87.1%) received bortezomib-based first-line therapy; 3 (9.6%) underwent autologous stem cell transplantation. Four patients (12.9%) underwent renal transplantation. The median follow-up duration was 8 months (range 4 - 96 months). The hematologic response was observed in 23/31 patients (74.1%); the median time to best hematologic response was 6 months (range 4-12 months). The renal response was observed in 16/31 patients (51.6%); the median time to best renal response was 12 months (range 6 – 24 months). Normal eGFR at baseline and achievement of CR/VGPR with therapy were independent predictors of renal response. Seven patients died during follow-up. The overall survival (OS) of the study cohort was 77.4%. **Conclusions:** These findings suggest that achieving deep hematologic responses with bortezomib-based therapy is crucial to obtaining renal responses in MGRS patients. Low eGFR at baseline is a risk factor for suboptimal renal response.

P-429

Real-world data of zanubrutinib treatment for patients with previously treated Waldenstrom Macroglobulinemia

Seo Yoon Jang[1], Soyean Kwon[1], Ja Min Byun[1], Youngil Koh[1], Junshik Hong[1], Sung-Soo Yoon[1]

[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea

Introduction: Waldenstrom macroglobulinemia (WM) is defined as lymphoplasmacytic lymphoma (LPL) associated with immunoglobulin M (IgM) monoclonal gammopathy, irrespective of the M protein size. The treatment of goal of WM is to control disease without compromising quality of life by treatment-related adverse events. Zanubrutinib, a second generation covalent BTK inhibitor, constitute the incumbent stand of care irrespective of line of therapy based on the recent success of ASPEN trial. Recognizing the lack of real-world data on zanubrutinib treatment for previously treated WM patients, we carried out this study. **Methods:** We conducted a retrospective cohort study of previously treated WM patients and identified 10 patients undergoing zanubrutinib treatment. All patients started on 160mg bid schedule The efficacy and safety of zanubrutinib treatment was investigated. The response was evaluated according to the 6th International Workshop on WM. Major response was defined as composite of complete response (CR) + very good partial response (VGPR) + partial response (PR). Overall response rate (ORR) was defined as minor response (MR) or better response. **Results:** The median age at WM diagnosis was 65, while the median age at zanubrutinib start was 70 years old. There were 7 males and 3 females. There were 2 patients with underlying arrhythmias and 1 with hypertension. The median time from diagnosis to zanubrutinib was 52 months (range 8-145), and 6 patients had 2 prior lines of therapy while 4 had 1 prior line of therapy. All but 2 were previously treated with chemoimmunotherapy, and there were 4 patients previous exposure to bortezomib. The median time from last line of therapy to zanubrutinib was 4 months (range 0-72 months). The reason for starting zanubrutinib were neuropathy (2), anemia (1), kidney-related (3), extramedullary manifestation (1), Bing Neel Syndrome (1), and physician's decision (2). During the median follow-up of 17 months, 5 (50%) achieved VGPR, 4 (40%) achieved PR and 1 (10%) achieved MR. ORR was 100% and major response 100% without CR. There was 1 patient with prior exposure to ibrutinib: this patient achieved PR after 6 months of treatment. The median time to initial response was 39 days, median time to best response 9 months, and median duration of response 15 months. One patient underwent dose reduction (to 80mg bid) due to dyspnea. There was 1 case of grade 1 thrombocytopenia. Otherwise, zanubrutinib was well tolerated. **Conclusions:** Real-world data are consistent with previously published data from trials with zanubrutinib in WM.

Introduction: Monoclonal gammopathy of renal significance (MGRS) refers to a heterogeneous group of disorders where abnormal monoclonal protein produced by a plasma cell or B-cell clone results in renal dysfunction. These are rare disorders and do not meet diagnostic criteria for other hematologic malignancies. There is limited literature on MGRS from India. **Methods:** We performed a retrospective analysis of MGRS patients treated at PGIMER Chandigarh from January 2013 to December 2022. All patients required confirmation of MGRS on renal biopsy for inclusion in the study. Patients with cast nephropathy and renal AL Amyloidosis were excluded. Hematologic response was defined as complete response (CR) if normalization of FLC was achieved. Very good partial response (VGPR) and partial response (PR) required 90% or 50% monoclonal protein reduction, respectively. Renal response was defined as >30% reduction of 24 h proteinuria (in the absence of renal progression). **Results:** A total of 31 MGRS patients were analyzed. The median age at diagnosis was 48 years (range 29 – 65 years); 45.2% were females. The median duration of symptoms was 6 months (range 1 – 24 months). Most common presenting complaints were fatigue (82.8%), pedal edema (64.5%), and frothuria (32.2%). At presentation, 20 patients (64.5%) had eGFR 1 renal lesion on kidney biopsy. Most patients (n = 27; 87.1%) received bortezomib-based first-line therapy; 3 (9.6%) underwent autologous stem cell transplantation. Four patients (12.9%) underwent renal transplantation. The median follow-up duration was 8 months (range 4 - 96 months). The hematologic response was observed in 23/31 patients (74.1%); the median time to best hematologic response was 6 months (range 4-12 months). The renal response was observed in 16/31 patients (51.6%); the median time to best renal response was 12 months (range 6 – 24 months). Normal eGFR at baseline and achievement of CR/VGPR with therapy were independent predictors of renal response. Seven patients died during follow-up. The overall survival (OS) of the study cohort was 77.4%. **Conclusions:** These findings suggest that achieving deep hematologic responses with bortezomib-based therapy is crucial to obtaining renal responses in MGRS patients. Low eGFR at baseline is a risk factor for suboptimal renal response.

Real-world data of zanubrutinib treatment for patients with previously treated Waldenstrom Macroglobulinemia

Seo Yoon Jang[1], Soyean Kwon[1], Ja Min Byun[1], Youngil Koh[1], Junshik Hong[1], Sung-Soo Yoon[1]

[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea

Introduction: Waldenstrom macroglobulinemia (WM) is defined as lymphoplasmacytic lymphoma (LPL) associated with immunoglobulin M (IgM) monoclonal gammopathy, irrespective of the M protein size. The treatment of goal of WM is to control disease without compromising quality of life by treatment-related adverse events. Zanubrutinib, a second generation covalent BTK inhibitor, constitute the incumbent stand of care irrespective of line of therapy based on the recent success of ASPEN trial. Recognizing the lack of real-world data on zanubrutinib treatment for previously treated WM patients, we carried out this study. **Methods:** We conducted a retrospective cohort study of previously treated WM patients and identified 10 patients undergoing zanubrutinib treatment. All patients started on 160mg bid schedule The efficacy and safety of zanubrutinib treatment was investigated. The response was evaluated according to the 6th International Workshop on WM. Major response was defined as composite of complete response (CR) + very good partial response (VGPR) + partial response (PR). Overall response rate (ORR) was defined as minor response (MR) or better response. **Results:** The median age at WM diagnosis was 65, while the median age at zanubrutinib start was 70 years old. There were 7 males and 3 females. There were 2 patients with underlying arrhythmias and 1 with hypertension. The median time from diagnosis to zanubrutinib was 52 months (range 8-145), and 6 patients had 2 prior lines of therapy while 4 had 1 prior line of therapy. All but 2 were previously treated with chemoimmunotherapy, and there were 4 patients previous exposure to bortezomib. The median time from last line of therapy to zanubrutinib was 4 months (range 0-72 months). The reason for starting zanubrutinib were neuropathy (2), anemia (1), kidney-related (3), extramedullary manifestation (1), Bing Neel Syndrome (1), and physician's decision (2). During the median follow-up of 17 months, 5 (50%) achieved VGPR, 4 (40%) achieved PR and 1 (10%) achieved MR. ORR was 100% and major response 100% without CR. There was 1 patient with prior exposure to ibrutinib: this patient achieved PR after 6 months of treatment. The median time to initial response was 39 days, median time to best response 9 months, and median duration of response 15 months. One patient underwent dose reduction (to 80mg bid) due to dyspnea. There was 1 case of grade 1 thrombocytopenia. Otherwise, zanubrutinib was well tolerated. **Conclusions:** Real-world data are consistent with previously published data from trials with zanubrutinib in WM.

Incidence of primary plasma cell leukemia with the new diagnostic criteria

Virginia Jano[1], Irene Padilla[1], Marta Castellanos[1], Belen Ballina[1], María del Carmen Gilabert[1], Javier Sánchez-Real[1], Agata Almela[1], Abdolah Ahmadi[1], Jose Antonio Rodríguez[1], Fernando Escalante[1]

[1]University Hospital of Leon

Introduction: Plasma cell leukemia (PCL) is the most aggressive form of plasma cell neoplasms, accounting for 1% of this group. Traditionally, PCL has been defined by a peripheral blood plasma cell count >2x10^9/L or a peripheral blood smear plasma cell count >20% of total nucleated cells. However, the latest recommendations suggest that the required percentage for diagnosis should be reduced to 5%. This is because patients with Multiple Myeloma (MM) with circulating plasma cells levels starting from this threshold have a poor prognosis, similar to patients traditionally diagnosed with PCL. **Methods:** Objective: The objective of this study is to describe the epidemiological and clinical characteristics and analyze the treatment response in patients diagnosed with primary plasma cell leukemia (pPCL). Materials and methods: This is a descriptive, retrospective study in which a search was conducted for patients meeting the new criteria for pPCL in our center between January 2021 and May 2023. **Results:** The studied patients were in an age range from 45 to 87 years, with 85.7% of cases being women. All cases with available cytogenetic studies at the time of analysis showed adverse cytogenetic abnormalities. The average peripheral blood plasma cell count was 19.6%, with a count higher than 5% in all cases and only 42.9% exceeding 20%. Regarding treatment, individualized regimens were decided based on age and comorbidities. Thus, 71.4% of patients were considered suitable for intensive treatment with different regimens reflected in Table 2. Of these, 40% achieved complete response (CR) and another 40% achieved very good partial response (VGPR), without subsequent disease progression. The response in one patient cannot be evaluated because she had recently started treatment. Symptomatic/palliative treatment was decided for two cases: one of them achieved a partial response (PR) which he maintained for a year, but finally the disease progressed and the patient died. The other patient started treatment while these data were being analyzed. **Conclusions:** Currently, the incidence of pPCL with the new diagnostic criteria is unknown, but in our case series, the cumulative incidence is 2 cases per 100,000 inhabitants in two years and five months, much higher than those reported in other series (4 cases per 10 million inhabitants). This could reflect that the disease has been underdiagnosed for years, and the modification of diagnostic criteria will allow early identification of these patients. This, combined with the therapeutic arsenal available, could have significant results in the overall survival of these patients. The treatment of these patients is a challenge, with no defined guideline regardless of whether they are eligible or non-eligible for autologous stem cell transplantation (HSCT) In them, the best available treatment should be initiated as soon as possible.

Introduction: Recently, the diagnostic criteria for plasma cell leukemia (PCL) were revised to lower the cut-off value of 5% circulating plasma cells (CPCs) in peripheral blood smear. **Methods:** This retrospective study evaluated the clinical characteristics, prognostic factors and treatment outcomes in patients diagnosed with primary PCL based on the revised criteria. **Results:** At diagnosis, 127 patients diagnosed with primary PCL; 70 had CPCs ≥ 20%, and 57 had CPCs 5-19%. The study found no significant difference in progression free survival (PFS) and overall survival (OS) between the two groups (CPCs≥ 20% and 5-19%), but patients with CPCs≥20% had significantly higher white blood cell counts, lactate dehydrogenase levels and extramedually plasmacytoma compared to those with CPCs 5-19%. Multivariate analysis identified poor performance status, thrombocytopenia and del17p as significant predictor of OS. In this study, 33 patients underwent 18F-FDG PET/CT prior to initial treatments, and 11 showed more than 3 focal lesions. However, there was no difference of survival outcomes according to the PET/CT postivity. In addition, patients who achieved a complete response (CR) after induction therapy showed significantly improved PFS and OS than other patients. When evaluating response rates according to the induction therapies such as daratumumab-based quadruplets, bortezomib and thalidomide or bortezomib and lenalidomide combinations, bortezomib-based combinations, and IMiDs based combinations, CR rate was the highest in daratumumab-based quadruplets than other induction therapy. **Conclusions:** In conclusion, while there were some clinical

Nasopharyngeal plasmacytoma with tumefactive amyloidosis ("amyloidoma") presenting with unilateral hearing loss

Elif Sakci[1], Metban Guzel Mastanzade[1], Beyza Sen[1], Zakir Sakci[2], Ipek Yonal Hindilerden[1], Sevgi Kalayoglu-Besisik[1]

[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Hematology; [2]Umraniye Training and Research Hospital

Introduction: Amyloid light chain deposition may be localized primarily in the aerodigestive system. A rare presentation type is a discrete mass the formation of termed amyloidoma, which may be associated with monoclonal plasma cells in the interstitium of amyloid tissue. Amyloidoma may be localized as primary solitary amyloidoma and has in general an excellent prognosis with surgical management but may result in morbidity due to mass effect. The detection of light chain amyloid may be the first sign of an underlying lymphoproliferative disorder (LPD). It is imperative, therefore, to evaluate in detail to pursue a systemic disease. **Methods:** Our case presentation was as nasopharyngeal plasmacytoma with amyloidoma imitating localized solitary involvement but had systemic plasma cell dyscrasia. **Results:** A 30-year-old male presented with hearing loss and ear pain. Otoscopy suggested unilateral serous otitis media. A course of antimicrobial treatment was ineffective and magnetic resonance imaging was performed which showed mucosal thickening. Histologic examination of laryngoscopic biopsy sample showed amorphous eosinophilic material stained positive with Congo red and IgD kappa-type monoclonal plasma cell infiltration in the interstitium. A PET-CT did not show an LPD-pointing lesion except for an inflammatory change in bilateral rosenmuller fossa with minimal FDG uptake. He had a low level of M protein at 0.3 gr/dl with an abnormal free light chain ratio as being of 9. The paraprotein was IgD kappa type and bone marrow proved to be a clonal plasma cell dyscrasia with an increase of less than 10%. A debulking surgery was performed followed by curative radiotherapy. Despite all of these serum paraprotein levels showed a progressive increase and systemic remission induction was decided. A combined treatment modality as VTD-PACE was used for stem cell mobilization and six courses of VRD was given as anti-plasma cell therapy which succeeded paraprotein decrease. Consolidation was with a high dose of melphalan rescued by autologous stem cell transplantation (ASCT). The patient achieved complete remission. **Conclusions:** AAmyloidoma, is a benign, but rare form of amyloidosis, and surgical resection may result in a favorable prognosis. According to the involved organ or location, amyloidoma may not be completely resectable and radiotherapy may support mass reduction. In our case, however, amyloidoma was associated with plasmacytoma and systemic plasma cell dyscrasia as bone marrow involvement. The effective resolution was achieved after surgery with radiotherapy followed by anti-plasma cell therapy as remission induction and consolidation with ASCT.

Targeting free light chain secretion via botulinum neurotoxin is a novel therapeutic strategy in AL amyloidosis by inducing a terminal unfolded protein response

Emre Karayol[1], Maria Moscvin[1], Tianzeng Chen[1], Peter Czarnecki[2], Annamaria Gulla[3], Kenneth Anderson[4], Giada Bianchi[1]

[1]Brigham and Women's Hospital; [2]Beth Israel Deaconess Medical Center; [3]Candiolo Cancer Institute; [4]LeBow Institute for Myeloma Therapeutics and Jerome Lipper Center for Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, Massachusetts

Introduction: AL amyloidosis (AL) is an incurable plasma cell (PC) disorder with only one FDA-approved therapy. Deposition of immunoglobulin free light chain (FLC) fibrils in target organs is the sole pathogenic mechanism in AL. However, therapeutic strategies directly targeting FLC secretion are not available. SNARE proteins, the specific target of botulinum neurotoxin (BoNT), mediate docking and fusion of secretory vesicles. We hypothesized that targeting specific sets of SNAREs via BoNT will block FLC exocytosis, causing retention of FLC-loaded vesicles and triggering a terminal unfolded protein response (UPR) and apoptosis in AL cells. We postulate that SNAREs are potential novel targets in AL and other plasma cell disorders. **Methods:** We stably expressed 7 distinct, inducible BoNT serotypes (BoNT/A-F) in FLC-secreting AL (ALMC1 and ALMC2) and multiple myeloma (MM, KMS11) cell lines via tetracycline-inducible (Tet-On) bicistronic lentiviral vectors with a P2A-GFP which allowed us to use GFP as a biomarker of BoNT expression. We established monoclones of successfully transduced cells for each BoNT. We performed flow cytometry to assess kinetics of GFP induction and assess for apoptosis via AnnexinV/DAPI staining. Western blot (WB) was used to assess cleavage of SNAREs upon expression of each BoNT serotype. We used WB and ELISA to assess FLC secretion per cell upon BoNT expression. We used TurboID proximity labeling followed by mass spectrometry to identify cytotoxic BoNT interacting partners. We used RNP-based CRISPR-Cas9 gene editing to knock out (KO) putative BoNT targets. **Results:** By querying the IFM170 gene expression database of newly diagnosed MM patients, we identified VAMP2, VAMP3, and SNAP23 as the top expressed SNAREs. Their high expression was retained in a large AL and MM cell line panel. Expression of all BoNT serotypes, except BoNT B, led to rapid apoptosis of AL and MM cells, with BoNT F standing out for extent and rapidity of cytotoxicity. Dual cleavage of SNAP23 and VAMP3 correlated with cytotoxicity of BoNT in AL and MM cell lines. Mechanistically, we showed that cytotoxic BoNTs, but not non-toxic BoNT B, led to decreased FLC secretion and increased FLC retention and triggered the PERK pathway of the UPR with

and laboratory differences bwteeen patients with CPCs 5-19% and ≥ 20%, there was no difference in survival outcomes. Achieving CR after induction therapy was crucial for improving survival outcomes, and daratumumab-based quadruplets may be reasonable choice as an induction therapy for primary PCL.

Introduction: AL amyloidosis (AL) is an incurable plasma cell (PC) disorder with only one FDA-approved therapy. Deposition of immunoglobulin free light chain (FLC) fibrils in target organs is the sole pathogenic mechanism in AL. However, therapeutic strategies directly targeting FLC secretion are not available. SNARE proteins, the specific target of botulinum neurotoxin (BoNT), mediate docking and fusion of secretory vesicles. We hypothesized that targeting specific sets of SNAREs via BoNT will block FLC exocytosis, causing retention of FLC-loaded vesicles and triggering a terminal unfolded protein response (UPR) and apoptosis in AL cells. We postulate that SNAREs are potential novel targets in AL and other plasma cell disorders. **Methods:** We stably expressed 7 distinct, inducible BoNT serotypes (BoNT/A-F) in FLC-secreting AL (ALMC1 and ALMC2) and multiple myeloma (MM, KMS11) cell lines via tetracycline-inducible (Tet-On) bicistronic lentiviral vectors with a P2A-GFP which allowed us to use GFP as a biomarker of BoNT expression. We established monoclones of successfully transduced cells for each BoNT. We performed flow cytometry to assess kinetics of GFP induction and assess for apoptosis via AnnexinV/DAPI staining. Western blot (WB) was used to assess cleavage of SNAREs upon expression of each BoNT serotype. We used WB and ELISA to assess FLC secretion per cell upon BoNT expression. We used TurboID proximity labeling followed by mass spectrometry to identify cytotoxic BoNT interacting partners. We used RNP-based CRISPR-Cas9 gene editing to knock out (KO) putative BoNT targets. **Results:** By querying the IFM170 gene expression database of newly diagnosed MM patients, we identified VAMP2, VAMP3, and SNAP23 as the top expressed SNAREs. Their high expression was retained in a large AL and MM cell line panel. Expression of all BoNT serotypes, except BoNT B, led to rapid apoptosis of AL and MM cells, with BoNT F standing out for extent and rapidity of cytotoxicity. Dual cleavage of SNAP23 and VAMP3 correlated with cytotoxicity of BoNT in AL and MM cell lines. Mechanistically, we showed that cytotoxic BoNTs, but not non-toxic BoNT B, led to decreased FLC secretion and increased FLC retention and triggered the PERK pathway of the UPR with

increased expression of CHOP and GADD34 preceding onset of apoptosis. We identified SNAP23 as an interacting partner of cytotoxic BoNT F, but not non-toxic BoNT B. KO experiment showed SNAP23 KO to be partially toxic for AL and MM cell lines but did not recapitulate the effects of cytotoxic BoNTs entirely, suggesting "synthetic lethality" with concurrent targeting of yet unidentified SNAREs. **Conclusions:** Our data provide proof of concept that blocking FLC secretion in AL and MM cells is feasible and results in rapid cell apoptosis by triggering a terminal UPR, thus representing a promising, novel therapeutic approach. Using BoNT as a biological tool, we identified SNAP23 as a critical component of FLC exocytosis, paving the way for the design of novel therapeutics.

A patient with CD20-positive small cell variant plasma cell myeloma misdiagnosed as lymphoplasmacytic lymphoma

Miyoung Kim[1], Daehyun Chu[1], Young-Uk Cho[1], Sang-Hyun Hwang[1], Seongsoo Jang[1], Eul-Ju Seo[1], Han-Seung Park[1]

[1]Asan Medical Center, University of Ulsan College of Medicine

Introduction: We report a patient with CD20-positive light chain-type small cell variant plasma cell myeloma who was misdiagnosed with lymphoplasmacytic lymphoma and did not respond to anti-CD20 immunotherapy. **Methods:** Not applicable **Results:** An 80-year-old Korean man with pancytopenia visited our institution in August 2020. He had undergone a hemithyroidectomy for follicular thyroid carcinoma 6 years prior. His complete blood count showed hemoglobin (Hb), 88 g/L; white blood cells (WBCs), 3.4×10^9/L; and platelets, 106×10^9/L. Small mature-looking lymphocytes comprised 50,0% of all leukocytes; rouleaux formation was absent. In the bone marrow (BM) aspirate, 15.0% of total nucleated cells were mature lymphocytes, and 25.8% were plasma cells. On immunohistochemistry (IHC) of the BM biopsy sample, both the lymphocytes and plasma cells were positive for CD20, CD138, and kappa; partially positive for CD117; and negative for lambda. His serum calcium, creatinine, protein, and albumin levels were 8.2 mg/dL, 0.91 mg/dL, 6.9 g/dL, and 3.9 g/dL, respectively. Serum protein electrophoresis (PEP) and immunofixation electrophoresis (IFE) showed an M-peak of 0.2 g/dL (free kappa type). Urine PEP and IFE showed a monoclonal band of 47.5% (free kappa type). The serum free kappa/lambda light chain ratio was 1121.59:1. The karyotype was 42,XY,del(1)(q12),add(7)(p21),del(8)(q12q23),-9,add(10)(p13),+add(11)(p11.2),-13,-14,der(14)t(1;14)(p22;q32),add(16)(q11.2),add(17)(p11.2),add(17)(q25),-20,-20,add(22)(q13)[10]/46,XY[40]. The patient was diagnosed with lymphoplasmacytic lymphoma based on cell morphology and CD20-positivity and was treated with five cycles of a bendamustine-rituximab regimen for 17 months. Three subsequent BM analyses showed findings similar to the original, suggesting disease persistence. His pancytopenia was sustained with Hb, 69 g/L; WBC, 2.2×10^9/L; and platelets, 100×10^9/L. Plasmacytoid cells comprised 18,0% of all leukocytes with no rouleaux formation observed; they also comprised 77.0% of the BM aspirate, resembling small or plasmacytoid lymphocytes. The BM cellularity was 90%, mostly with plasmacytoid cells that were positive for CD138, kappa, CD20, and CD117; partially positive for CD56, CD79a, and cyclin D1; and negative for CD3, lambda, and PAX5. Flow cytometric immunophenotyping showed a large CD45-negative population that was positive for CD138, CD38, CD20, and CD56 but negative for CD19 and surface light chain. Based on these findings, the diagnosis was revised to plasma cell myeloma, small cell variant. The patient refused further treatment owing to his poor general condition. **Conclusions:** Small cell-variant plasma cell myeloma could be misdiagnosed as other mature B-cell neoplasms owing to its small lymphocyte-like morphology, frequent CD20-positivity, and frequent light chain type that lacks a rouleaux formation. Flow cytometric immunophenotyping and IHC for CD45 and CD138 may assist in the differential diagnosis.

Introduction: Monoclonal gammopathy of undetermined significance (MGUS) is a common condition that results from a small and/or quiescent secreting B-cell clone, completely asymptomatic, that requires only regular monitoring. Sometimes, although quiescent and not requiring any treatment per se, the clone is associated with potentially severe organ damage due to the toxicity of the monoclonal immunoglobulin. This situation refers to the concept of monoclonal gammopathy of clinical significance (MGCS). It is increasingly observed but still poorly recognized and frequently undertreated, although it often requires rapid specific intervention to preserve involved organ function. Here, we report a case of MGCS relying on manifestations of an acquired angioedema related to a monoclonal protein. **Methods:** A 48-year-old male patient presented in February 2020 with a first attack of angioedema that manifested by a swelling of the hands, feet and lips, and abdominal pain, that resolved within 24 hours. Lab test documented a low C1 inhibitor level (below 16%) with low C1 inhibitor activity (19%), and very low C4 and C1q levels, leading to the diagnosis of acquired angioedema. The patient had no personal nor familial history of angioedema. Additional work-up encompassed serum and urine protein electrophoresis, free light chain assay, lymphocyte typing by flow cytometry, bone marrow aspiration and PET-CT but was not conclusive. Treatment successively included Tranexamic Acid, plasma exchanges, 4 infusions of Rituximab, Mycophenolate Mofetil without any improvement, persistent angioedema attacks occurring every 3 to 4 weeks. **Results:** The patient was then referred to our center in September 2021. With subcutaneous injections of lanadelumab, an IgG1 Kappa monoclonal antibody directed against Kallikrein received on a compassionate use basis, he was freed from all symptoms till the program was stopped and attacks reoccurred.

increased expression of CHOP and GADD34 preceding onset of apoptosis. We identified SNAP23 as an interacting partner of cytotoxic BoNT F, but not non-toxic BoNT B. KO experiment showed SNAP23 KO to be partially toxic for AL and MM cell lines but did not recapitulate the effects of cytotoxic BoNTs entirely, suggesting "synthetic lethality" with concurrent targeting of yet unidentified SNAREs. **Conclusions:** Our data provide proof of concept that blocking FLC secretion in AL and MM cells is feasible and results in rapid cell apoptosis by triggering a terminal UPR, thus representing a promising, novel therapeutic approach. Introduction: Monoclonal gammopathy of undetermined significance (MGUS) is a common condition that results from a small and/or quiescent secreting B-cell clone, completely asymptomatic, that requires only regular monitoring. Sometimes, although quiescent and not requiring any treatment per se, the clone is associated with potentially severe organ damage due to the toxicity of the monoclonal immunoglobulin. This situation refers to the concept of monoclonal gammopathy of clinical significance (MGCS). It is increasingly observed but still poorly recognized and frequently undertreated, although it often requires rapid specific intervention to preserve involved organ function. Here, we report a case of MGCS relying on manifestations of an acquired angioedema related to a monoclonal protein. **Methods:** A 48-year-old male patient presented in February 2020 with a first attack of angioedema that manifested by a swelling of the hands, feet and lips, and abdominal pain, that resolved within 24 hours. Lab test documented a low C1 inhibitor level (below 16%) with low C1 inhibitor activity (19%), and very low C4 and C1q levels, leading to the diagnosis of acquired angioedema. The patient had no personal nor familial history of angioedema. Additional work-up encompassed serum and urine protein electrophoresis, free light chain assay, lymphocyte typing by flow cytometry, bone marrow aspiration and PET-CT but was not conclusive. Treatment successively included Tranexamic Acid, plasma exchanges, 4 infusions of Rituximab, Mycophenolate Mofetil without any improvement, persistent angioedema attacks occurring every 3 to 4 weeks. **Results:** The patient was then referred to our center in September 2021. With subcutaneous injections of lanadelumab, an IgG1 Kappa monoclonal antibody directed against Kallikrein received on a compassionate use basis, he was freed from all symptoms till the program was stopped and attacks reoccurred.

Additional work-up identified then an IgA Lambda monoclonal peak (1.9 g/L), with a discrete marrow infiltration, a situation considered as a MGCS. Treatment with SQ Daratumumab was proposed with the initial disappearance of any angioedema attack after the first 2 months of therapy, but relapses thereafter, persisting after 6 cycles of SQ Daratumumab. The patient was further rechallenged with lanadelumab with success. **Conclusions:** We report a case of acquired angioedema, a rare form of MGCS, that exemplifies the difficulty to understand the relationship between a monoclonal component and the clinical manifestations of the disease, since a therapy targeting directly the clone was not efficacious in this setting. This case also highlights the spectrum of various disorders associated with MGUS.

Clonal hematopoiesis of indeterminate potential (CHIP) in patients with amyloid light chain (AL) amyloidosis

Paolo Lopedote[1], Alfredo Marchetti[2], Benjamin Evans[3], Shannon Miller[4], Tianzeng Chen[5], Maria Moscvin[6], Niccolo' Bolli[7], Giada Bianchi[8]

[1]St Elizabeth's Medical Center; [2]Universita' degli studi di Milano; [3]Brigham and Women's Hospital; [4]Dana Farber Cancer Center; [5]Medical College of Wisconsin; [6]Stanford Health Care; [7]Division of Hematology & Stem Cell Transplantation, University of Milano, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy; [8]Brigham and Women/s Hospital/Harvard Medical School/Dana Farber Cancer Institute

Introduction: The hallmark of AL Amyloidosis is the production, aggregation, and deposition of immunoglobulin free light chains in target organs. Cardiac events are the major cause of mortality in AL amyloidosis. Clonal hematopoiesis of unknown potential (CHIP) is associated with increased cardiovascular risk in the general population and decreased overall survival in multiple myeloma patients receiving autologous stem cell transplant. Large studies looking at incidence and outcome of patients with concurrent CHIP and AL amyloidosis are missing. We performed a single center, retrospective analysis to evaluate the prevalence of CHIP in AL amyloidosis and associated disease characteristics and outcomes, including major organ dysfunction progression free survival (MOD-PFS). **Methods:** Demographics and clinical characteristics of patients diagnosed with AL amyloidosis at DFCI from January 2018 to April 2023 who received a bone marrow aspirate/biopsy with a rapid heme panel (RHP) were collected. Variables of interest included age, ethnicity, Mayo stage, Palladini renal stage, involved organs, FISH abnormalities, left ventricular ejection fraction, and anginal symptoms. MOD-PFS was defined based on Kastritis et al. Variant alle fraction (VAF) to define CHIP was set at 2%. Two samples independent t-test, Wilcoxon rank sum test, Fisher exact test were used for comparison between groups. We used the Cox proportional hazard regression model to estimate the association between CHIP status and MOD-PFS. All analyses were carried out with the STATA statistical package. This study was approved by the institutional review board. **Results:** Seventy-six patients were identified meeting criteria. Of these, 16 (21%) were found to meet diagnostic criteria for CHIP. DNMT3A was the most frequently involved gene (7/16, 44%), followed by GNB1, TET2, ATM (each 2/16, 12.5%), and SF3B1, ZRSR2, EZH2, BRCC3, PPM1D, ASXL1 (6%). Among the variables of interest, patients with CHIP had a higher prevalence of t(11;14) (11/13, 85%, versus 15/41, 37%, p=0.004) and a lower Palladini renal stage (p=0.001). Median follow-up time for the entire cohort was 25 months (range 1 – 175 months). In a univariate analysis model, CHIP presence was not associated with an increased hazard for lower MOD-PFS (hazard ratio 0.998, 95% CI 0.38 – 2.64), although a limited number of events was recorded given short duration of follow up. **Conclusions:** This is the first, large series describing the prevalence and clinical implications of CHIP in patients with AL amyloidosis. In our study, CHIP was associated with presence of t(11;14), the most frequent cytogenetics in AL amyloidosis and a negative prognostic factor. A lower Palladini renal risk score was noted in patients with CHIP. Because of the limited number of events, no multi-variate Cox regression analysis was performed. Future studies will help confirm our findings and clarify the impact of CHIP in AL amyloidosis patients' outcome.

Minor salivary gland biopsy versus bone marrow biopsy for the diagnosis of amyloidosis AL: a comparative retrospective study

Gianluca Maiorana[1], Agostino Tafuri[1], Giorgio Bandiera[1], Armando Bartolazzi[1], Chiara Togni[1], Valentina De Santis[1], Giusy Antolino[1], Sabrina Mariani[1], Giacinto La Verde[1]

[1]Sant Andrea University Hospital, Sapienza University, Rome, Italy

Introduction: Amyloidosis AL is a challenging hematological disorder characterized by the extracellular deposition of misfolded monoclonal light chains. Timely and accurate diagnosis is crucial for appropriate management and prognosis. A large portion of patients has a history of monoclonal gammopathy of undetermined significance (MGUS) and therefore bone marrow biopsy (BMB) is generally the most used and best evaluated technique for diagnosing Amyloidosis AL. Other techniques like abdominal fat pad biopsy and skin biopsy are valid and common alternatives. Minor salivary gland biopsy (MSGB) has emerged as a less invasive alternative, offering a promising diagnostic approach but its application is often considered a second option. In this study, we aimed to evaluate the usefulness of MSGB compared to BMB for the diagnosis of amyloidosis AL. **Methods:** We conducted a retrospective analysis of 85 patients who underwent both MSGB and BMB for suspected amyloidosis AL from January 2009 to April 2023. All biopsies were evaluated using Congo red staining and immunohistochemistry for amyloid typing. Clinical data, including demographic information, laboratory results, histological characteristics and diagnostic outcomes, were collected. All patients had a monoclonal gammopathy with a clinical or serological suspect for Amyloidosis AL. **Results:** Of the 85 patients included in the study, 32 were diagnosed with amyloidosis AL. Among these 32 patients, 21 had positive MSGB and 14 had positive BMB, resulting in a sensitivity of 65.5% (95% CI 46.81% to 81.43%) and 43.75% (95% CI 26.36% to 62.34%) respectively.

Additional work-up identified then an IgA Lambda monoclonal peak (1.9 g/L), with a discrete marrow infiltration, a situation considered as a MGCS. Treatment with SQ Daratumumab was proposed with the initial disappearance of any angioedema attack after the first 2 months of therapy, but relapses thereafter, persisting after 6 cycles of SQ Daratumumab. The patient was further rechallenged with lanadelumab with success. **Conclusions:** We report a case of acquired angioedema, a rare form of MGCS, that exemplifies the difficulty to understand the relationship between a monoclonal component and the clinical manifestations of the disease, since a therapy targeting directly the clone was not efficacious in this setting. This case also highlights the spectrum of various disorders associated with MGUS.

This study was approved by the institutional review board. **Results:** Seventy-six patients were identified meeting criteria. Of these, 16 (21%) were found to meet diagnostic criteria for CHIP. DNMT3A was the most frequently involved gene (7/16, 44%), followed by GNB1, TET2, ATM (each 2/16, 12.5%), and SF3B1, ZRSR2, EZH2, BRCC3, PPM1D, ASXL1 (6%). Among the variables of interest, patients with CHIP had a higher prevalence of t(11;14) (11/13, 85%, versus 15/41, 37%, p=0.004) and a lower Palladini renal stage (p=0.001). Median follow-up time for the entire cohort was 25 months (range 1 – 175 months). In a univariate analysis model, CHIP presence was not associated with an increased hazard for lower MOD-PFS (hazard ratio 0.998, 95% CI 0.38 – 2.64), although a limited number of events was recorded given short duration of follow up. **Conclusions:** This is the first, large series describing the prevalence and clinical implications of CHIP in patients with AL amyloidosis. In our study, CHIP was associated with presence of t(11;14), the most frequent cytogenetics in AL amyloidosis and a negative prognostic factor. A lower Palladini renal risk score was noted in patients with CHIP. Because of the limited number of events, no multi-variate Cox regression analysis was performed. Future studies will help confirm our findings and clarify the impact of CHIP in AL amyloidosis patients' outcome.

Minor salivary gland biopsy versus bone marrow biopsy for the diagnosis of amyloidosis AL: a comparative retrospective study

Gianluca Maiorana[1], Agostino Tafuri[1], Giorgio Bandiera[1], Armando Bartolazzi[1], Chiara Togni[1], Valentina De Santis[1], Giusy Antolino[1], Sabrina Mariani[1], Giacinto La Verde[1]

[1]Sant Andrea University Hospital, Sapienza University, Rome, Italy

Introduction: Amyloidosis AL is a challenging hematological disorder characterized by the extracellular deposition of misfolded monoclonal light chains. Timely and accurate diagnosis is crucial for appropriate management and prognosis. A large portion of patients has a history of monoclonal gammopathy of undetermined significance (MGUS) and therefore bone marrow biopsy (BMB) is generally the most used and best evaluated technique for diagnosing Amyloidosis AL. Other techniques like abdominal fat pad biopsy and skin biopsy are valid and common alternatives. Minor salivary gland biopsy (MSGB) has emerged as a less invasive alternative, offering a promising diagnostic approach but its application is often considered a second option. In this study, we aimed to evaluate the usefulness of MSGB compared to BMB for the diagnosis of amyloidosis AL. **Methods:** We conducted a retrospective analysis of 85 patients who underwent both MSGB and BMB for suspected amyloidosis AL from January 2009 to April 2023. All biopsies were evaluated using Congo red staining and immunohistochemistry for amyloid typing. Clinical data, including demographic information, laboratory results, histological characteristics and diagnostic outcomes, were collected. All patients had a monoclonal gammopathy with a clinical or serological suspect for Amyloidosis AL. **Results:** Of the 85 patients included in the study, 32 were diagnosed with amyloidosis AL. Among these 32 patients, 21 had positive MSGB and 14 had positive BMB, resulting in a sensitivity of 65.5% (95% CI 46.81% to 81.43%) and 43.75% (95% CI 26.36% to 62.34%) respectively.

Additional work-up identified then an IgA Lambda monoclonal peak (1.9 g/L), with a discrete marrow infiltration, a situation considered as a MGCS. Treatment with SQ Daratumumab was proposed with the initial disappearance of any angioedema attack after the first 2 months of therapy, but relapses thereafter, persisting after 6 cycles of SQ Daratumumab. The patient was further rechallenged with lanadelumab with success. **Conclusions:** We report a case of acquired angioedema, a rare form of MGCS, that exemplifies the difficulty to understand the relationship between a monoclonal component and the clinical manifestations of the disease, since a therapy targeting directly the clone was not efficacious in this setting. This case also highlights the spectrum of various disorders associated with MGUS.

Introduction: The hallmark of AL Amyloidosis is the production, aggregation, and deposition of immunoglobulin free light chains in target organs. Cardiac events are the major cause of mortality in AL amyloidosis. Clonal hematopoiesis of unknown potential (CHIP) is associated with increased cardiovascular risk in the general population and decreased overall survival in multiple myeloma patients receiving autologous stem cell transplant. Large studies looking at incidence and outcome of patients with concurrent CHIP and AL amyloidosis are missing. We performed a single center, retrospective analysis to evaluate the prevalence of CHIP in AL amyloidosis and associated disease characteristics and outcomes, including major organ dysfunction progression free survival (MOD-PFS). **Methods:** Demographics and clinical characteristics of patients diagnosed with AL amyloidosis at DFCI from January 2018 to April 2023 who received a bone marrow aspirate/biopsy with a rapid heme panel (RHP) were collected. Variables of interest included age, ethnicity, Mayo stage, Palladini renal stage, involved organs, FISH abnormalities, left ventricular ejection fraction, and anginal symptoms. MOD-PFS was defined based on Kastritis et al. Variant alle fraction (VAF) to define CHIP was set at 2%. Two samples independent t-test, Wilcoxon rank sum test, Fisher exact test were used for comparison between groups. We used the Cox proportional hazard regression model to estimate the association between CHIP status and MOD-PFS. All analyses were carried out with the STATA statistical package. This study was approved by the institutional review board. **Results:** Seventy-six patients were identified meeting criteria. Of these, 16 (21%) were found to meet diagnostic criteria for CHIP. DNMT3A was the most frequently involved gene (7/16, 44%), followed by GNB1, TET2, ATM (each 2/16, 12.5%), and SF3B1, ZRSR2, EZH2, BRCC3, PPM1D, ASXL1 (6%). Among the variables of interest, patients with CHIP had a higher prevalence of t(11;14) (11/13, 85%, versus 15/41, 37%, p=0.004) and a lower Palladini renal stage (p=0.001). Median follow-up time for the entire cohort was 25 months (range 1 – 175 months). In a univariate analysis model, CHIP presence was not associated with an increased hazard for lower MOD-PFS (hazard ratio 0.998, 95% CI 0.38 – 2.64), although a limited number of events was recorded given short duration of follow up. **Conclusions:** This is the first, large series describing the prevalence and clinical implications of CHIP in patients with AL amyloidosis. Introduction: Amyloidosis AL is a challenging hematological disorder characterized by the extracellular deposition of misfolded monoclonal light chains. Timely and accurate diagnosis is crucial for appropriate management and prognosis. A large portion of patients has a history of monoclonal gammopathy of undetermined significance (MGUS) and therefore bone marrow biopsy (BMB) is generally the most used and best evaluated technique for diagnosing Amyloidosis AL. Other techniques like abdominal fat pad biopsy and skin biopsy are valid and common alternatives. Minor salivary gland biopsy (MSGB) has emerged as a less invasive alternative, offering a promising diagnostic approach but its application is often considered a second option. In this study, we aimed to evaluate the usefulness of MSGB compared to BMB for the diagnosis of amyloidosis AL. **Methods:** We conducted a retrospective analysis of 85 patients who underwent both MSGB and BMB for suspected amyloidosis AL from January 2009 to April 2023. All biopsies were evaluated using Congo red staining and immunohistochemistry for amyloid typing. Clinical data, including demographic information, laboratory results, histological characteristics and diagnostic outcomes, were collected. All patients had a monoclonal gammopathy with a clinical or serological suspect for Amyloidosis AL. **Results:** Of the 85 patients included in the study, 32 were diagnosed with amyloidosis AL. Among these 32 patients, 21 had positive MSGB and 14 had positive BMB, resulting in a sensitivity of 65.5% (95% CI 46.81% to 81.43%) and 43.75% (95% CI 26.36% to 62.34%) respectively.

Concomitant positivity was present in 8 cases. Of the 64 patients with negative MSGB, 53 were not diagnosed with Amyloidosis AL, resulting in a specificity of 99.5% (95% CI: 93.28% to 99.9%). 4 patients with negative MSGB but positive BMB received diagnosis of Amyloidosis AL. 7 patients were diagnosed with Amyloidosis AL despite both negative MSGB and BMB. Of the 53 patients without Amyloidosis AL, 25 received diagnosis of Smouldering Myeloma, 14 of Multiple Myeloma, 4 of Waldenstrom Macroglobulinemia and 10 of MGUS. **Conclusions:** To our knowledge, this is one of the largest studies comparing salivary gland and bone marrow biopsies as diagnostic tools in Amyloidosis AL. Our findings demonstrate that minor salivary gland biopsy is a valuable and reliable option with a sensitivity non inferior to other alternatives and, in our case, higher than bone marrow biopsy, thus providing valuable diagnostic information when positive. Comparing our results with data from studies evaluating different bioptic methods for Amyloidosis AL, MSGB holds promise as an initial diagnostic approach, potentially sparing patients from the risks associated with more invasive procedures. Further studies with larger sample sizes and prospective designs are warranted to validate our results and establish standardized protocols for minor salivary gland biopsy as frontrunner in the diagnosis of Amyloidosis AL.

Castleman disease: histopathologic reclassification, clinical characteristics and endpoints in a reference center in Mexico

Deborah Martinez Baños[1], Alfonso Orozco Collazo[1], Daniel Montante Montes[1], Sergio Rodriguez Rodriguez[1], Isabel Garcia Carrera[1], Jesus Sandoval Lopez[1], Maria Jose Lizardo Thiebaud[1], Cinthya Monroy Ramos[1], Berta Riveros Gilardi[1], Alec Seidman Sorsby[1]

[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán

Introduction: Castleman's Disease (CD) circumscribes several clinicopathologic disorders at the intersection of hematology, oncology, rheumatology and virology, with convergence in histopathologic and clinical features. Information about CD in Latin America is scarce. **Methods:** Patients with CD diagnosis from January 2006 to July 2022 were included. A retrospective review of the clinical charts and examination of the biopsies by a trained hematopathologist was performed. The immunohistochemical panel was extended to exclude differentials and PCR to confirm infection by HHV8 and classification of the cases. **Results:** Twenty-seven patients were included; 37% were unicentric Castleman disease (UCD) and 63% multicentric Castleman disease (MCD); median age at diagnosis was 37 and 41 years respectively; 80% of women in UCD and 76% of men in MCD (p=0.018). In UCD the most frequent nodal areas affected were cervical in 40% and mesenteric in 40%. Media nodal size was 7.1 cm; the 80% hyaline vascular (HV) variety and 20% mixed variant (MV). Successful surgical removal was performed in all cases and none of the patients have relapsed. The distribution of MCD was 59% idiopathic MCD (iMCD), 35% associated to POEMS syndrome and 6% to HHV8. Fifty-nine percent experienced B symptoms, 70% presented fluid retention and 35% experienced skin involvement. Hepatomegaly was present in 88% and splenomegaly in 53%, mean 18.3 cm and 14.6 cm respectively. The treatment received by 16 patients with MCD was only chemotherapy in 37%, rituximab as monotherapy in 19%, rituximab in combination with corticosteroids 19% and 25% in combination with CHOP-like chemotherapy. Response to treatment was evaluable in 13 patients: 38% achieved a complete response, 38% a partial response, 15% stable disease and one patient progressive disease. The revision of the cases derived in the reclassification of 13 %. Cases were more frequently reclassified in MCD. At 66 months follow-up, median overall survival, and progression free survival have not been reached. Patients with MCD associated to POEMS Syndrome relapsed more frequently 83% vs 17% (p=0.005). Uni and multivariate analysis revealed that the association to POEMS Syndrome increased relapse risk OR 50 (IC 95% 2.559 - 976), p=0.010 and OR 31.64 (IC 95% 1.48-676), p=0.027, respectively. Median PFS in this group was 53 months vs non reached in patients with iMCD or associated to HHV8 (p=0.031). **Conclusions:** This is the first series of CD cases in the Latin population that includes a complete description of the clinical and histopathological characteristics and reclassification according to current diagnostic criteria. Opposed to data reported in the literature, the MV corresponded to 20% of UCD and showed a predominance of cervical nodal involvement. Different from data published, in our cohort we found less mediastinal involvement in UCD (10% vs 16-40%). In MCD associated to POEMS Syndrome, the PFS was inferior, the poor outcome of this association had not been previously described.

Identifying early suboptimal haematological response in patients with AL amyloidosis treated with bortezomib-based chemotherapy

Peter Mollee[1], Anthea Gibbons[1], Niri Ranjit Anderson[1], Dariusz Korczyk[1], Simon Gibbs[2], Hasib Sidiqi[3]

[1]Princess Alexandra Hospital; [2]Eastern Health Monash University Clinical School; [3]Fiona Stanley Hospital, WA, Australia

Introduction: The achievement of rapid, deep haematological response is critical in the treatment of AL amyloidosis. The timing and depth of FLC reduction that defines suboptimal response and the need to switch to second-line therapy is uncertain. We aimed to determine the impact of haematological response after 2 months of bortezomib-based therapy on subsequent best haematological and organ responses and survival. **Methods:** Subjects had a histological diagnosis of AL amyloidosis, symptomatic organ involvement and initial treatment with a bortezomib-based regimen. The impact of haematological response after 2 months of treatment on subsequent best haematological and renal response was assessed using Fisher's exact test. The impact on OS was assessed by landmark analysis using log-rank or Cox regression analysis. **Results:** 150 patients with AL amyloidosis were identified: Median age was 66 yrs and 35% were male. 75% of cases were lambda restricted, the median dFLC was 160mg/L, 75% had ≥ 10% bone marrow plasmacytosis and 9% had symptomatic myeloma. Cardiac stage was: 1 (13%), 2 (55%), 3A

Concomitant positivity was present in 8 cases. Of the 64 patients with negative MSGB, 53 were not diagnosed with Amyloidosis AL, resulting in a specificity of 99.5% (95% CI: 93.28% to 99.9%). 4 patients with negative MSGB but positive BMB received diagnosis of Amyloidosis AL. 7 patients were diagnosed with Amyloidosis AL despite both negative MSGB and BMB. Of the 53 patients without Amyloidosis AL, 25 received diagnosis of Smouldering Myeloma, 14 of Multiple Myeloma, 4 of Waldenstrom Macroglobulinemia and 10 of MGUS. **Conclusions:** To our knowledge, this is one of the largest studies comparing salivary gland and bone marrow biopsies as diagnostic tools in Amyloidosis AL. Our findings demonstrate that minor salivary gland biopsy is a valuable and reliable option with a sensitivity non inferior to other alternatives and, in our case, higher than bone marrow biopsy, thus providing valuable diagnostic information when positive. Comparing our results with data from studies evaluating different bioptic methods for Amyloidosis AL, MSGB holds promise as an initial diagnostic approach, potentially sparing patients from the risks associated with more invasive procedures. Further studies with larger sample sizes and prospective designs are warranted to validate our results and establish standardized protocols for minor salivary gland biopsy as frontrunner in the diagnosis of Amyloidosis AL.

Identifying early suboptimal haematological response in patients with AL amyloidosis treated with bortezomib-based chemotherapy

Peter Mollee[1], Anthea Gibbons[1], Niri Ranjit Anderson[1], Dariusz Korczyk[1], Simon Gibbs[2], Hasib Sidiqi[3]

[1]Princess Alexandra Hospital; [2]Eastern Health Monash University Clinical School; [3]Fiona Stanley Hospital, WA, Australia

Introduction: The achievement of rapid, deep haematological response is critical in the treatment of AL amyloidosis. The timing and depth of FLC reduction that defines suboptimal response and the need to switch to second-line therapy is uncertain. We aimed to determine the impact of haematological response after 2 months of bortezomib-based therapy on subsequent best haematological and organ responses and survival. **Methods:** Subjects had a histological diagnosis of AL amyloidosis, symptomatic organ involvement and initial treatment with a bortezomib-based regimen. The impact of haematological response after 2 months of treatment on subsequent best haematological and renal response was assessed using Fisher's exact test. The impact on OS was assessed by landmark analysis using log-rank or Cox regression analysis. **Results:** 150 patients with AL amyloidosis were identified: Median age was 66 yrs and 35% were male. 75% of cases were lambda restricted, the median dFLC was 160mg/L, 75% had ≥ 10% bone marrow plasmacytosis and 9% had symptomatic myeloma. Cardiac stage was: 1 (13%), 2 (55%), 3A

(17%) and 3B (15%). 71% had renal involvement with a median eGFR of 69mls/min and median proteinuria of 2.4g/d, with 9% dialysis dependent at presentation. Bortezomib regimens were: VCD (72%), VCD+daratumumab (13%), MDV (7%), VD (6%) and VRD (3%), with a median of 6 cycles delivered. Median OS was 6.2 years which was adversely associated with more advanced cardiac disease: stage 1 (not reached), stage 2 (90 months), stage 3A (52 months) and stage 3B (9 months)(p=0.0001). Haematological response after 2 months of bortezomib-based induction was: CR (17%), VGPR (40%), PR (17%) and less than PR (16%). 10% of patients died prior to 2 month response assessment. Failure to achieve PR by 2 months was associated with a low chance of achieving deep responses, with only 5% going on to achieve VGPR or better (p< 0.001). Similarly, failure to achieve PR by 2 months predicted a low likelihood of improving organ function with less chance of cardiac (6% vs 47%, p=0.001) and renal (20% vs 41%, p=0.044) responses. In a landmark analysis, failure to achieve PR after 2 months predicted worse OS (median 48 vs 93 months, p=0.041), a finding confirmed in multivariate analysis including cardiac stage. This effect was particularly evident for patients with cardiac stage 3A and 3B disease, where the early achievement of PR was associated with a median OS of 70 months vs 7 months if PR was not achieved. Failure to achieve VGPR by 2 months was not associated with therapeutic futility, with 65% of patients going on to achieve VGPR or better as their best response. **Conclusions:** Failure to achieve haematological PR after 2 months of bortezomib-based therapy is associated low likelihood of subsequently achieving deep haematological response and organ responses and predicts poor survival, especially for cardiac stage 3A and 3B disease. Such patients should be switched to alternate salvage therapy.

Introduction: The R2-ISS risk stratification system revises the R-ISS scoring system to improve risk stratification in newly diagnosed multiple myeloma (NDMM). The R2-ISS scoring system was derived in a clinical trial population composed mainly of European patients and hence by default the treatments those patients received were different to current standards of care in different parts of the world. Further, the applicability of this scoring in a real-world population from Asia remains unknown. The aim of this study was to explore the validity of the R2-ISS scoring system in a real-world Asian population we applied the R2-ISS scoring to a cohort of Asian patients recruited into the Asia-Pacific (APAC) Myeloma and Related Diseases Registry (MRDR). Registry patients from 4 participating Asian countries/regions across multiple sites from Korea, Singapore, Malaysia and Taiwan were included. **Methods:** R2-ISS scoring was retrospectively applied to a NDMM cohort from the APAC MRDR diagnosed between 1st January 2018 and 22nd October 2022. The Kaplan-Meier method was used to plot curves for progression-free survival (PFS) and overall survival (OS). Different risk groups were compared using the log-rank test. **Results:** Of the 946 patients in the APAC MRDR from the 4 countries, complete staging data (ISS, LDH and FISH) was available for 642 patients. The median follow-up for the entire cohort was 12.3 months. Top 5 treatment regimens used for the whole cohort were VCD / VTD / RD / VMP and VRD. R2-ISS delineated the patients into 4 groups (Categories 1-4) with median PFS of NR, 29, 25 and 15 months respectively. PFS difference was significant between R2-ISS I vs III and R2-ISS I vs IV but not between R2-ISS I vs II. Similarly, OS was significantly longer for R2-ISS I vs IV group patients only. OS was not significantly different for R2-ISS I vs II whilst I vs III showed a trend towards significance. Of the 372 patients originally belonging to the R-ISS2 category, 2, 114, 240 and 16 patients were re-classified as R2-ISS 1,2,3,4 groups respectively (mPFS 7, 29, 25 and 13 months). Apart from the 2 patients with R2-ISS score 1, the PFS of the rest of R2-ISS score patients delineated suggesting the validity of this scoring system in this group of patients. When R2ISS groups 1&2 and 3&4 were pooled together PFS was NR Vs 21.2 months. OS is not mature at the present time. **Conclusions:** In this analysis, the R2-ISS system was able to stratify our cohort of Asian NDMM patients into four risk groups according to PFS. OS data is immature and longer follow-up is required. However, the clear distinction between groups I versus II was not seen in this real-world study likely due to the very low numbers in group 1. The R2-ISS effectively differentiates the R-ISS stage II category, addressing a disadvantage of the R-ISS system.

Soluble urokinase plasminogen activator receptor (SuPAR) in patients with plasma cell dyscrasias, a pilot study

Yashwanth Sudhini[1], Binod Dhakal[2], Jochen Reiser[1], Mehmet Altintas[1], Eunsil Hahm[1], Vasil Peev[1], Parameswaran Venugopal[1], Agne Paner[1]

[1]Rush University Medical Center; [2]Medical College of Wisconsin, Milwaukee, WI, USA

Introduction: Soluble Urokinase Plasminogen Activator Receptor (SuPAR) is an inflammatory mediator of kidney injury in various clinical settings. SuPar levels have been found to be higher in patients with multiple myeloma (MM) when compared to healthy controls, and have been correlated with worse kidney function in MM pts. However, data is limited to its role in mediating kidney injury and

(17%) and 3B (15%). 71% had renal involvement with a median eGFR of 69mls/min and median proteinuria of 2.4g/d, with 9% dialysis dependent at presentation. Bortezomib regimens were: VCD (72%), VCD+daratumumab (13%), MDV (7%), VD (6%) and VRD (3%), with a median of 6 cycles delivered. Median OS was 6.2 years which was adversely associated with more advanced cardiac disease: stage 1 (not reached), stage 2 (90 months), stage 3A (52 months) and stage 3B (9 months)(p=0.0001). Haematological response after 2 months of bortezomib-based induction was: CR (17%), VGPR (40%), PR (17%) and less than PR (16%). 10% of patients died prior to 2 month response assessment. Failure to achieve PR by 2 months was associated with a low chance of achieving deep responses, with only 5% going on to achieve VGPR or better (p< 0.001). Similarly, failure to achieve PR by 2 months predicted a low likelihood of improving organ function with less chance of cardiac (6% vs 47%, p=0.001) and renal (20% vs 41%, p=0.044) responses. In a landmark analysis, failure to achieve PR after 2 months predicted worse OS (median 48 vs 93 months, p=0.041), a finding confirmed in multivariate analysis including cardiac stage. This effect was particularly evident for patients with cardiac stage 3A and 3B disease, where the early achievement of PR was associated with a median OS of 70 months vs 7 months if PR was not achieved. Failure to achieve VGPR by 2 months was not associated with therapeutic futility, with 65% of patients going on to achieve VGPR or better as their best response. **Conclusions:** Failure to achieve haematological PR after 2 months of bortezomib-based therapy is associated low likelihood of subsequently achieving deep haematological response and organ responses and predicts poor survival, especially for cardiac stage 3A and 3B disease. Such patients should be switched to alternate salvage therapy.

Soluble urokinase plasminogen activator receptor (SuPAR) in patients with plasma cell dyscrasias, a pilot study

Yashwanth Sudhini[1], Binod Dhakal[2], Jochen Reiser[1], Mehmet Altintas[1], Eunsil Hahm[1], Vasil Peev[1], Parameswaran Venugopal[1], Agne Paner[1]

[1]Rush University Medical Center; [2]Medical College of Wisconsin, Milwaukee, WI, USA

Introduction: Soluble Urokinase Plasminogen Activator Receptor (SuPAR) is an inflammatory mediator of kidney injury in various clinical settings. SuPar levels have been found to be higher in patients with multiple myeloma (MM) when compared to healthy controls, and have been correlated with worse kidney function in MM pts. However, data is limited to its role in mediating kidney injury and

ultimately renal recovery. In this pilot study we compared baseline suPAR values between patients with MM requiring treatment and those with smoldering state or MGUS. We also determined whether suPAR levels correlate with the level of renal impairment, response to myeloma treatment and kidney recovery. **Methods:** SuPAR levels were measured in patients at the time of diagnosis, including seven patients with smoldering myeloma or MGUS and 11 patients with newly diagnosed MM requiring treatment. Among patients undergoing treatment for MM suPAR levels were repeated after induction therapy and after autologous stem cell transplant (ASCT). Renal function and MM response to treatment were assessed at the same time points. **Results:** Patients with smoldering myeloma and MGUS had lower average suPAR level 3.35 ng/ml (SD +/- 1.78) than patients with MM requiring treatment 4.5 ng/ml (SD +/- 1.97) at baseline, but it was not statistically significant (p 0.22). Average suPAR level was higher in patients with glomerular filtration rate (GFR) of less than 40 ml/min/1.73 m^2 compared to the rest of study subjects 3.85 (SD +/- 1.8) vs 4.74 (SD +/- 2.44), but also not statistically significant (0.49). Four patients in the study underwent treatment for MM and had serial measurements of SuPAR levels. All patients achieved VGPR or better to the induction regimen. Two of the three patients with available data had a decline in suPAR level after induction regimen and kidney function remained stable. One patient had stable suPAR level around 3 ng/ml and showed improvement of kidney function. **Conclusions:** This pilot study shows that suPAR levels are elevated both in patients with multiple myeloma requiring treatment and patients with MGUS and smoldering multiple myeloma. We found no difference in suPAR levels in patients with MM and GFR of less than 40 ml/min/1.73 m^2 vs more than 40 ml/min/1.73 m^2. A suPAR level around 3 ng/ml before or after treatment appears to be beneficial for stable or improving kidney function. This finding supports further study of suPAR as a prognostic factor in multiple myeloma. SuPAR effect on myeloma prognosis and GFR in patients with renal impairment, will be evaluated in a large phase 2 trial Bortezomib, Isatuximab, Cyclophosphamide and Dexamethasone Induction in Transplant-Eligible Multiple Myeloma Patients (NCT04240054).

P-442

Imaging cardiac amyloidosis using 18F-florbetaben positron electron topography (PET) in systemic light chain (AL) amyloidosis

Nirija Ranjit Anderson[1], Joshua Tobin[1], Phillip Law[1], Peter Mollee[1]

[1]Princess Alexandra Hospital, Queensland Health

Introduction: 18F-florbetaben is a novel radiotracer that has previously demonstrated capability in delineating between cardiac amyloidosis and other causes of cardiac hypertrophy. We aim to assess the utility of 18F-florbetaben PET for cardiac imaging in patients with systemic AL to define cardiac involvement at baseline and following treatment. **Methods:** Newly diagnosed or relapsed patients with systemic AL amyloidosis and cardiac involvement, as determined by 2D speckled transthoracic echocardiogram and cardiac biomarkers, between June 2018 and December 2020 were approached to undertake a PET scan using 18F-florbetaben. Mean and maximal left ventricular (LV) myocardial standardised uptake values (SUV) were recorded and used to graph time activity curves (TAC). Percentage myocardial 18F-florbetaben retention was calculated from the TAC and compared with the following variables: LV global longitudinal strain (GLS) and intraventricular septal wall thickness (IVs); serum brain natriuretic peptide (BNP) and cardiac troponin I (cTnI), using Pearson Correlation for statistical analysis. Pearson's chi-squared test was used for correlation between cardiac staging (using Mayo 2004 staging for AL amyloidosis) and SUV. The Kaplan-Meir method was used to calculate overall survival. **Results:** 12 patients with systemic AL amyloidosis and suspected cardiac involvement (11 newly diagnosed, 1 relapsed) underwent a 18F-florbetaben PET scan prior to commencement of systemic therapy; 42% were female with a mean age of 63 years at diagnosis. There were 5 deaths (42%), all related to progressive AL amyloidosis. Two-year survival was 58.3%, with a mean overall survival of 7.3 years (95% CI 4.08 – 10.52). Statistical significance was not reached but there was a trend towards correlation between percentage myocardial 18F-florbetaben retention and LV GLS (r=0.5, p=0.08). There was no correlation demonstrated between IVs, BNP or cTnI in this study. There was also a trend towards higher SUVmean with stage 3 cardiac amyloidosis, which holds prognostic relevance clinically as these patients have a significantly lower overall survival. Of note, a previously defined cut-off in a pilot study using a percentage myocardial 18F-florbetaben retention of less than 40% to exclude cardiac amyloidosis did prompt review of 2 patients' cases in this cohort and findings supported either an alternative cause of heart failure or low likelihood of cardiac involvement with AL amyloidosis (IgM type, with normal cardiac biomarkers and borderline echocardiogram findings). **Conclusions:** The utility of 18F-florbetaben PET in AL amyloidosis is complementary to currently available assessment tools and may add value in patients with potentially multifactorial causes of cardiac dysfunction, those with unclear cardiac involvement as part of their initial work up, and to identify patients with more severe cardiac amyloid burden. Analysis of serial imaging at end of treatment to assess role in monitoring of disease burden and organ response will follow.

P-443

Localised light chain (AL) amyloidosis: presentation, treatment and outcomes; an observational study

Nirija Ranjit Anderson[1], Emad Abro[1], Dariusz Korczyk[1], Peter Mollee[1]

[1]Princess Alexandra Hospital, Queensland Health

Introduction: Localised immunoglobulin light chain associated amyloid deposition is a rare disease. Tissue biopsy does not discriminate between localised and systemic forms of amyloidosis, thus clinical assessment of pattern of presentation, organ involvement and the presence or absence of a monoclonal component is required to discern between the two. Treatment recommendations are vastly different dependent on this diagnosis. We report the clinical characteristics, treatment modalities and outcomes in

ultimately renal recovery. In this pilot study we compared baseline suPAR values between patients with MM requiring treatment and those with smoldering state or MGUS. We also determined whether suPAR levels correlate with the level of renal impairment, response to myeloma treatment and kidney recovery. **Methods:** SuPAR levels were measured in patients at the time of diagnosis, including seven patients with smoldering myeloma or MGUS and 11 patients with newly diagnosed MM requiring treatment. Among patients undergoing treatment for MM suPAR levels were repeated after induction therapy and after autologous stem cell transplant (ASCT). Renal function and MM response to treatment were assessed at the same time points. **Results:** Patients with smoldering myeloma and MGUS had lower average suPAR level 3.35 ng/ml (SD +/- 1.78) than patients with MM requiring treatment 4.5 ng/ml (SD +/- 1.97) at baseline, but it was not statistically significant (p 0.22). Average suPAR level was higher in patients with glomerular filtration rate (GFR) of less than 40 ml/min/1.73 m^2 compared to the rest of study subjects 3.85 (SD +/- 1.8) vs 4.74 (SD +/- 2.44), but also not statistically significant (0.49). Four patients in the study underwent treatment for MM and had serial measurements of SuPAR levels. All patients achieved VGPR or better to the induction regimen. Two of the three patients with available data had a decline in suPAR level after induction regimen and kidney function remained stable. One patient had stable suPAR level around 3 ng/ml and showed improvement of kidney function. **Conclusions:** This pilot study shows that suPAR levels are elevated both in patients with multiple myeloma requiring treatment and patients with MGUS and smoldering multiple myeloma. Imaging cardiac amyloidosis using 18F-florbetaben positron electron topography (PET) in systemic light chain (AL) amyloidosis

Nirija Ranjit Anderson[1], Joshua Tobin[1], Phillip Law[1], Peter Mollee[1]

[1]Princess Alexandra Hospital, Queensland Health

Introduction: 18F-florbetaben is a novel radiotracer that has previously demonstrated capability in delineating between cardiac amyloidosis and other causes of cardiac hypertrophy. We aim to assess the utility of 18F-florbetaben PET for cardiac imaging in patients with systemic AL to define cardiac involvement at baseline and following treatment. **Methods:** Newly diagnosed or relapsed patients with systemic AL amyloidosis and cardiac involvement, as determined by 2D speckled transthoracic echocardiogram and cardiac biomarkers, between June 2018 and December 2020 were approached to undertake a PET scan using 18F-florbetaben. Mean and maximal left ventricular (LV) myocardial standardised uptake values (SUV) were recorded and used to graph time activity curves (TAC). Percentage myocardial 18F-florbetaben retention was calculated from the TAC and compared with the following variables: LV global longitudinal strain (GLS) and intraventricular septal wall thickness (IVs); serum brain natriuretic peptide (BNP) and cardiac troponin I (cTnI), using Pearson Correlation for statistical analysis. Pearson's chi-squared test was used for correlation between cardiac staging (using Mayo 2004 staging for AL amyloidosis) and SUV. The Kaplan-Meir method was used to calculate overall survival. **Results:** 12 patients with systemic AL amyloidosis and suspected cardiac involvement (11 newly diagnosed, 1 relapsed) underwent a 18F-florbetaben PET scan prior to commencement of systemic therapy; 42% were female with a mean age of 63 years at diagnosis. There were 5 deaths (42%), all related to progressive AL amyloidosis. Two-year survival was 58.3%, with a mean overall survival of 7.3 years (95% CI 4.08 – 10.52). Statistical significance was not reached but there was a trend towards correlation between percentage myocardial 18F-florbetaben retention and LV GLS (r=0.5, p=0.08). There was no correlation demonstrated between IVs, BNP or cTnI in this study. There was also a trend towards higher SUVmean with stage 3 cardiac amyloidosis, which holds prognostic relevance clinically as these patients have a significantly lower overall survival. Of note, a previously defined cut-off in a pilot study using a percentage myocardial 18F-florbetaben retention of less than 40% to exclude cardiac amyloidosis did prompt review of 2 patients' cases in this cohort and findings supported either an alternative cause of heart failure or low likelihood of cardiac involvement with AL amyloidosis (IgM type, with normal cardiac biomarkers and borderline echocardiogram findings). **Conclusions:** The utility of 18F-florbetaben PET in AL amyloidosis is complementary to currently available assessment tools and may add value in patients with potentially multifactorial causes of cardiac dysfunction, those with unclear cardiac involvement as part of their initial work up, and to identify patients with more severe cardiac amyloid burden. Analysis of serial imaging at end of treatment to assess role in monitoring of disease burden and organ response will follow.

Localised light chain (AL) amyloidosis: presentation, treatment and outcomes; an observational study

Nirija Ranjit Anderson[1], Emad Abro[1], Dariusz Korczyk[1], Peter Mollee[1]

[1]Princess Alexandra Hospital, Queensland Health

Introduction: Localised immunoglobulin light chain associated amyloid deposition is a rare disease. Tissue biopsy does not discriminate between localised and systemic forms of amyloidosis, thus clinical assessment of pattern of presentation, organ involvement and the presence or absence of a monoclonal component is required to discern between the two. Treatment recommendations are vastly different dependent on this diagnosis. We report the clinical characteristics, treatment modalities and outcomes in

patients with localised AL amyloidosis reviewed at a quaternary amyloidosis referral centre. **Methods:** Database and medical records for all patients referred between January 2010 to May 2023 with a confirmed diagnosis of localised AL amyloidosis were reviewed. Demographic data, sites of organ involvement, treatment received, and recurrence or progression were assessed for each patient. Overall survival was estimated by the Kaplan-Meier method. **Results:** 121 patients with localised AL amyloidosis were reviewed with the mean age of diagnosis being 58.4 years; 48% were female. The most common sites of presentation were pulmonary 20%, genitourinary and gastrointestinal tract with 18% each, followed by cutaneous/soft tissue 17%. Other commonly involved sites include the larynx and eye 10% each. Rarer sites were nodal 3%, central nervous system 2%, and nasopharynx 2%. 67% were treated with observation alone following their original biopsy. 21% had surgical management for symptomatic mass effect; the greatest proportion of these consisting of laryngeal or urinary tract involvement, with 28% and 24% respectively. 4% underwent radiotherapy for either an underlying lymphoproliferative disorder or for a site not amenable to surgery. 3% received systemic therapy (chemotherapy/immunotherapy), all were for localised nodal amyloid associated with lymphoma. 3% received other treatment options, such as autologous stem cell transplantation (for localised amyloid deposition associated with a plasmacytoma), topical therapy, or antiviral eradication therapy. The remaining 4% had incomplete records to enable assessment of treatment. Localised disease recurrence occurred in 14% of cases, with the most common site of recurrence being laryngeal at 30%. There was no progression to systemic AL amyloidosis in any patient. 10% of patients died during the review period, all from causes other than AL amyloidosis. The estimated 5-year overall survival was 91% (95% CI 83–96%) compared to 64% (95% CI 54-73%) for systemic AL amyloidosis. **Conclusions:** Localised AL amyloidosis is a distinctively different entity which needs to be distinguished from systemic amyloidosis, especially between AL and ATTR types. It has comparatively different presenting organ involvement patterns and a favourable natural history profile without active intervention in most cases. Localised site recurrences occur and can be managed through minimally invasive surgical approaches if symptomatic.

A comparison of immunohistochemistry and laser microdissection tandem mass spectrometry to identify the amyloid fibril protein from formalin-fixed paraffin embedded biopsy samples

James Rowland[1], Duncan Lambie[2], Dorothy Loo Oey[3], Kylie Cuthbertson[2], Simon Gibbs[4], Patrick Hosking[4], Fiona Kwok[5], Meena Shingde[6], Peter Mollee[1]

[1]Princess Alexandra Hospital; [2]Pathology Queensland, Princess Alexandra Hospital; [3]Translational Research Institute, Queensland, Australia; [4]Eastern Health Monash University Clinical School; [5]Westmead Amyloidosis Service, Westmead Hospital; [6]Department of Tissue Pathology, Westmead Hospital

Introduction: Correct diagnosis of amyloidosis subtype is a critical step to direct patient management, inform prognosis and guide targeted genetic testing. Laser capture microdissection and tandem mass spectrometry (LMD-MS) analysis of formalin-fixed paraffin-embedded (FFPE) biopsy samples is emerging as the new gold-standard diagnostic technique in amyloid subtyping, with likely superiority to conventional immunohistochemistry (IHC) based approaches. **Methods:** To assess this, a novel LMD-MS assay was developed. In brief, 10-micron sections were cut from FFPE biopsies, deparaffinised and stained with Congo red. Laser microdissection was performed of Congo red positive deposits. Proteins from dissected tissue were digested to peptides and analysed with high-performance liquid chromatography (HPLC) coupled with a ThermoFisher scientific Q Exactive plus mass spectrometer and peptide matches assessed against the Swiss-Prot/Uniprot human protein database with the addition of the Kabat library. 121 patient samples were assessed using both LMD-MS and an IHC panel consisting of 4 commercial antibodies: kappa, lambda, transthyretin and serum amyloid A. Each IHC was assessed independently by two experienced pathologists and graded quantitatively. LMD-MS was reported using institutional bioinformatic reporting algorithms. **Results:** Biopsy sites were most frequently renal (25.6%), cardiac (17%) and gastrointestinal tract (25.6%). IHC assessment was considered non-diagnostic in 44% of samples. 121 samples were assessed for LMD-MS and 110 were samples were suitable for analysis with the assay. An amyloid subtype was confidently identified in 96% of samples analysed, with only 4 samples not identifying an amyloid forming protein. Concordance was assessed between LMD-MS and IHC. 3 cases of IHC typed light chain amyloidosis were reclassified as non-AL amyloid types and 3 cases of IHC typed AA amyloidosis were reclassified as AL-amyloidosis, both with potentially significant therapeutic implications. **Conclusions:** Proteomic assessment of amyloid biopsy with laser capture microdissection and mass spectrometry is superior to immunohistochemical analysis using commercial antibodies for amyloidosis subtyping.

Waldenström Macroglobulinaemia lymphoma patients have impaired platelet haemostatic function

Dipti Talaulikar[1,2], Simone Brysland[2], Elizabeth Gardiner[2]

[1]Canberra Health Services; [2]Australian National University

Introduction: Waldenström Macroglobulinaemia (WM) is a B-cell lymphoma with clinical features including thrombocytopenia, IgM-mediated hyperviscosity, bleeding and bruising. Treatment of WM patients with Bruton's tyrosine kinase inhibitors (BTKis) may exacerbate bleeding risk. Abnormal haemostasis may result from platelet dysfunction and altered coagulation, however the extent of dysregulation of these processes in WM patients is unknown. We therefore aimed to evaluate haemostatic and platelet dysfunction in WM patients. **Methods:** Platelet receptor levels in samples from 19 clinically annotated WM patients or healthy donors (HDs) were measured by flow cytometry. Thrombin generation in plasma ± platelets was measured by fluorescence resonance energy transfer assay. Whole blood clotting potential was evaluated by rotational thromboelastometry (ROTEM). Levels of plasma soluble GPVI (sGPVI) and serum thrombopoietin (TPO) were measured by enzyme-linked immunosorbent assays. **Results:** WM platelets had reduced levels of GPIbα (p=0.0153), GPVI (p=0.0347) and reticulation (p=0.0005), and increased overall sialylation (p=0.0079) and tetraspanin CD9 levels (p< 0.0001). WM plasma displayed significantly reduced thrombin generation potential (p=0.0408) and WM platelets contributed less to thrombus initiation (p=0.0208) and rate (p< 0.0001) by ROTEM, but displayed normal responses to agonists, except in the presence of BTKis. Plasma sGPVI were within normal ranges and TPO levels were increased (p< 0.0001). **Conclusions:** The impaired haemostatic potential in WM samples was independent of BTKi therapy. Reduced platelet GPIbα and GPVI may arise from altered megakaryocyte maturation and thrombopoiesis, associated with bone marrow malignancy. Monitoring platelet and coagulation properties may help stratify WM patients for bleeding risk.

Daratumumab based Induction for plasma cell leukaemia & early ASCT: experience from a tertiary care hospital in North India

Sanjeev Yadav[1], Faheema Hasan[1], Dinesh Chandra[1], Manish Kumar Singh[1], Khaiqur Rahman[1], Ruchi Gupta[1], Rajesh Kashyap[1]

[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences

Introduction: Plasma cell leukaemia (PCL) is the most aggressive form of plasma cell dyscrasia. Usually It requires VDT-PACE like aggressive Induction chemotherapy. When patient is not fit for VDT –PACE, Daratumumab based Induction therapy is an option. **Methods:** We are presenting a case of plasma cell leukaemia treated with Daratumumab based induction Chemotherapy, followed by early autologous transplant **Results:** A 48 year old female referred to hematology department from Nephrology ICU, she was admitted to the nephrology ICU with Complaint of oliguria & CCF. She underwent 2 cycles of haemodialysis. On work up the cause of AKI was found to be plasma cell leukaemia. She was having IgG Lambda M band (Qty- 5.8g/dl), Sr Kappa -31, Sr Lambda- 11,000 & Kappa/lambda ratio of 0.002. Her Myeloma FISH panel was showing t (11; 14) & gain 1q. She was started on DARA-VCD induction, in view of fungal pneumonia at presentation. After 4 cycles of DARA-VCD chemotherapy, she was in VGPR, with M band of 0.2g/dl & Sr Lambda of 7. On pre-transplant workup she was MRD positive, PET negative, with eGFR of 29 ml/min/ 1.73m^2, PFT was showing mild restriction. She underwent G-CSF+ Plerixafor mobilization, with CD4 cell count of 3.9x 10^6 cells/Kg. Mel 140 conditioning was used for conditioning, due to her low eGFR. Febrile neutropenia, & Mucositis (Grade 3-4) was major issues during transplant otherwise she tolerated well. She engrafted for neutrophils on ay 12 & for platelets on day 15. There were no major complications till Day +100; Day +100 Marrow was MRD Negative. She was given 2 cycles of DARA-VCD consolidation & then switched to Dara/Bortezomib based maintenance therapy. She is absolutely fine, currently on Day +180. **Conclusions:** Daratumumab based Induction therapy is an important treatment alternative for VDT –PACE chemotherapy for PCL.A randomised control trial should be conducted in more number of patients.

the clinical diagnostic laboratory, optimisation and validation of this assay was required. **Methods:** LMD-MS was performed on 78 patient samples and results evaluated assessing key MS measurements and the identification of amyloid signature and amyloid forming proteins. The addition of the Kabat protein library to the Swiss-Prot/Uniprot database did not interfere with identification of the amyloid proteins and showed superior diagnostic yield. Technical changes including buffer formulation and MS analyser technology variation had no impact on amyloid forming protein identification. A bioinformatic reporting algorithm was created which confidently identified an amyloid subtype in 96.1% of patient samples. LMD-MS was shown to be superior to IHC in subtyping of amyloid proteins with a non-diagnostic rate of only 3.6% The local LMD-MS assay showed 100% concordance with international laboratory analysis. **Conclusions:** A novel LMD-MS assay has been developed and validated and shows superiority to the previous IHC based standard of care assessment and, while bioinformatic algorithm differs, gives identical information to LMD-MS from international centres.

Waldenström Macroglobulinaemia lymphoma patients have impaired platelet haemostatic function

Dipti Talaulikar[1,2], Simone Brysland[2], Elizabeth Gardiner[2]

[1]Canberra Health Services; [2]Australian National University

Introduction: Waldenström Macroglobulinaemia (WM) is a B-cell lymphoma with clinical features including thrombocytopenia, IgM-mediated hyperviscosity, bleeding and bruising. Treatment of WM patients with Bruton's tyrosine kinase inhibitors (BTKis) may exacerbate bleeding risk. Abnormal haemostasis may result from platelet dysfunction and altered coagulation, however the extent of dysregulation of these processes in WM patients is unknown. We therefore aimed to evaluate haemostatic and platelet dysfunction in WM patients. **Methods:** Platelet receptor levels in samples from 19 clinically annotated WM patients or healthy donors (HDs) were measured by flow cytometry. Thrombin generation in plasma ± platelets was measured by fluorescence resonance energy transfer assay. Whole blood clotting potential was evaluated by rotational thromboelastometry (ROTEM). Levels of plasma soluble GPVI (sGPVI) and serum thrombopoietin (TPO) were measured by enzyme-linked immunosorbent assays. **Results:** WM platelets had reduced levels of GPIbα (p=0.0153), GPVI (p=0.0347) and reticulation (p=0.0005), and increased overall sialylation (p=0.0079) and tetraspanin CD9 levels (p< 0.0001). WM plasma displayed significantly reduced thrombin generation potential (p=0.0408) and WM platelets contributed less to thrombus initiation (p=0.0208) and rate (p< 0.0001) by ROTEM, but displayed normal responses to agonists, except in the presence of BTKis. Plasma sGPVI were within normal ranges and TPO levels were increased (p< 0.0001). **Conclusions:** The impaired haemostatic potential in WM samples was independent of BTKi therapy. Reduced platelet GPIbα and GPVI may arise from altered megakaryocyte maturation and thrombopoiesis, associated with bone marrow malignancy. Monitoring platelet and coagulation properties may help stratify WM patients for bleeding risk.

Daratumumab based Induction for plasma cell leukaemia & early ASCT: experience from a tertiary care hospital in North India

Sanjeev Yadav[1], Faheema Hasan[1], Dinesh Chandra[1], Manish Kumar Singh[1], Khaiqur Rahman[1], Ruchi Gupta[1], Rajesh Kashyap[1]

[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences

Introduction: Plasma cell leukaemia (PCL) is the most aggressive form of plasma cell dyscrasia. Usually It requires VDT-PACE like aggressive Induction chemotherapy. When patient is not fit for VDT –PACE, Daratumumab based Induction therapy is an option. **Methods:** We are presenting a case of plasma cell leukaemia treated with Daratumumab based induction Chemotherapy, followed by early autologous transplant **Results:** A 48 year old female referred to hematology department from Nephrology ICU, she was admitted to the nephrology ICU with Complaint of oliguria & CCF. She underwent 2 cycles of haemodialysis. On work up the cause of AKI was found to be plasma cell leukaemia. She was having IgG Lambda M band (Qty- 5.8g/dl), Sr Kappa -31, Sr Lambda- 11,000 & Kappa/lambda ratio of 0.002. Her Myeloma FISH panel was showing t (11; 14) & gain 1q. She was started on DARA-VCD induction, in view of fungal pneumonia at presentation. After 4 cycles of DARA-VCD chemotherapy, she was in VGPR, with M band of 0.2g/dl & Sr Lambda of 7. On pre-transplant workup she was MRD positive, PET negative, with eGFR of 29 ml/min/ 1.73m^2, PFT was showing mild restriction. She underwent G-CSF+ Plerixafor mobilization, with CD4 cell count of 3.9x 10^6 cells/Kg. Mel 140 conditioning was used for conditioning, due to her low eGFR. Febrile neutropenia, & Mucositis (Grade 3-4) was major issues during transplant otherwise she tolerated well. She engrafted for neutrophils on ay 12 & for platelets on day 15. There were no major complications till Day +100; Day +100 Marrow was MRD Negative. She was given 2 cycles of DARA-VCD consolidation & then switched to Dara/Bortezomib based maintenance therapy. She is absolutely fine, currently on Day +180. **Conclusions:** Daratumumab based Induction therapy is an important treatment alternative for VDT –PACE chemotherapy for PCL.A randomised control trial should be conducted in more number of patients.

Impact of molecular cytogenetic abnormalities on the risk of disease progression in solitary bone plasmacytomas

Udit Yadav[1], Shaji Kumar[1], Angela Dispenzieri[1], Francis Buadi[1], David Dingli[1], Martha Lacy[1], Rafael Fonseca[2], Leif Bergsagel[2], Ricardo Parrondo[3], Suzanne Hayman[1], Prashant Kapoor[1], Nelson Leung[1], Joselle Cook[1], Moritz Binder[1], Abhishek Seth[1], Eli Muchtar[1], Rahma Warsame[1], Taxiarchis Kourelis[1], Sikander Ailawadhi[3], Vivek Roy[3], Ronald Go[1], Robert Kyle[1], Vincent Rajkumar[1], Wilson Gonsalves[1]

[1]Mayo Clinic, Rochester; [2]Mayo Clinic, Phoenix; [3]Mayo Clinic, Jacksonville

Introduction: The standard treatment for solitary bone plasmacytoma (SBP) with or without minimal marrow involvement is definitive radiation therapy followed by observation. However, most patients with SBP progress to MM. Whether the presence of high-risk (HR) cytogenetic abnormalities by FISH detected in the clonal plasma cells obtained either directly from the SBP tissue or the corresponding bone marrow aspirate performed at the time of diagnosis is associated with a shorter time to progression (TTP) to MM has not been studied to date. **Methods:** We evaluated all patients diagnosed with SBP with or without minimal marrow involvement seen at the Mayo Clinic from January 2012 to July 2022. The presence of del(17p), t(14;16), t(4;14), or +1q (gain or amplification) by FISH in clonal plasma cells was defined as HR. All patients were required to have had a biopsy-proven plasmacytoma arising from a bone, advanced cross-sectional imaging (positron emission tomography (PET)/computed tomography (CT), whole body-CT Skeletal Survey, or whole-body magnetic resonance imaging (WB-MRI)) demonstrating the absence of any additional lytic or FDG avid bone lesions or plasmacytomas, a posterior iliac crest bone marrow biopsy and aspirate containing fewer than 10% clonal plasma cells and no clinical evidence of CRAB symptoms (anemia, elevated creatinine and hypercalcemia) which would fulfill the diagnosis for MM as per the International Myeloma Working Group (IMWG) criteria. We excluded patients with concurrent light chain amyloidosis, POEMS syndrome, 10% or more plasma cells on bone marrow biopsy, and patients who fulfilled the criteria for smoldering or active MM. **Results:** A total of 114 patients were included in this cohort, and FISH was available for 55 patients (48.2%), of which 22 were classified as HR (40%). In patients with FISH results available, more patients with HR FISH (N = 20, 91%) progressed to MM compared to patients without HR FISH (N=16,48%) (p=0.0012) after a median follow-up of 54 months. The median TTP to MM for patients with HR FISH was 8 months (95%CI 6.3-26) compared to 42 months (95%CI 25-NR) in patients without HR FISH (p < 0.001). In patients with HR FISH, 59% progressed within 12 months of diagnosis compared to 15% of patients without HR FISH (p < 0.001) and 73% of patients with HR FISH progressed within 24 months of diagnosis compared to 27% of patients without HR FISH (p< 0.001). In a multivariate analysis, only the presence of HR FISH was a significant predictor for shorter TTP to MM, independent of the presence of minimal marrow involvement and an abnormal serum free light chain (sFLC) ratio at diagnosis. **Conclusions:** Patients with SBP and HR FISH have a significantly higher risk and shorter TTP to MM compared to patients with SBP and without HR FISH. There is an unmet need to investigate novel therapeutic strategies to prevent the rather rapid disease progression to MM in this patient population.

Role of education and empowerment in multiple myeloma patients

Jennifer Ahlstrom[1], Marilú Nájera Flores[1], Scott Campbell[2], Tara Roy[2], Patricia Alejandra Flores Pérez[1], Jorge Arturo Hurtado Martínez[1], Nathan Sweeney[1], Rachel Kremen[3], Jay Hydren[1]

[1]HealthTree Foundation; [2]Takeda Pharmaceuticals International Co.; [3]Lumanity

Introduction: Multiple myeloma (MM) significantly affects patients' (pts) lives, partly due to its complexity and variety of treatments. Health education has been reported to improve outcomes and self-management in cancer pts, suggesting that a growing abundance of resources to educate and empower could offset the burdens of MM. This study aimed to evaluate the impact of MM diagnosis on pts' lives and study the differences in education and empowerment between pts with Newly Diagnosed MM (NDMM) vs. Relapsed and Refractory MM (RRMM). **Methods:** HealthTree® Cure Hub for Multiple Myeloma is an online portal for pts with plasma cell dyscrasias to help navigate their disease. Using this platform, we conducted a 25-question survey covering patient education, empowerment, and the impact of MM diagnosis. We compared responses between NDMM and RRMM pts. The survey was determined to be of minimal risk and exempted by the WCG Institutional Review Board. **Results:** Of 250 survey participants, 54% were NDMM. The majority were females (53%), college-educated (75%), with an age of 67±8 yrs. At diagnosis, both groups reported obtaining diagnosis-related data mainly from their healthcare team (92%). However, NDMM pts report a higher use of social media for this purpose (26%) than RRMM (19%), and NDMM reported less usage of medical journals (22%) than RRMM (39%). Additionally, in both groups, there was a dramatic increase in the use of online patient advocacy groups to get disease-related information, from 52% (at diagnosis) to 82% (current). Moreover, 79% of pts in both groups reported having a strong or higher desire to learn more about future treatment options. Both felt empowered by their relationship with at least one member of their healthcare team (87%), aiding in information gathering and decision-making. Furthermore, both indicated that care partners play a role in emotional support (79%) and decision-making (59%). Frequent impacts of MM on both patient groups involve exercise (60%) and hobbies (54%). Mental health (53%) and financial impact (55%) significantly increased by 15%-20% in RRMM compared to NDMM (38% and 35%, respectively). The financial burden is moderate to significant for NDMM pts at 67%, and even more so for RRMM pts at 77%. This financial strain reflects why over

Comparison of a battery powered device (OnControl) versus manual Jamshidi needle for bone marrow biopsy in adult patients with plasma cell disorders: a prospective randomized control trial (RCT)

Joel Andrews[1], Nisha Joseph[1], Jessica Neely[1], Angela Hatcher[1], Cecilia Rosand[1], Alex Palmer[1], Maggie Harrington[1], Danielle Roberts[1], Caleb Raine[1], Rosie Pruitt[1], Vikas Gupta[1], Craig Hofmeister[1], Madhav Dhodapkar[1], Lawrence Boise[1], Charise Gleason[1], Jonathan Kaufman[1], Sagar Lonial[1], Ajay Nooka[1]

[1]Winship Cancer Institute, Emory University, Atlanta, GA, USA

Introduction: Bone marrow aspiration and biopsies (BMA&B) provide diagnostic and prognostic information in patients with plasma cell disorders. The use of Jamshidi needle for manual BMA&B has been the established method of choice. Powered biopsy devices (OnControl) are gaining popularity due to shorter procedural time and operator convenience, but are limited by increased incidence of crush artifact and inadequate sampling. We performed a prospective randomized control trial (RCT) to assess the quality of BMA&B and the patient and provider convenience. **Methods:** Adult patients with plasma cell disorders undergoing BMA&B were consented by nine operators who are familiar with both techniques. A total of 100 patients underwent randomization to receive BMA&B by OnControl drill vs manual Jamshidi needle. A questionnaire was used to assess the intensity of pain and the impact of BMA&B on general activity, work, and sleep at baseline and on days 1, 3 and 7. Sedation information, time for completion of procedure, and demographic data were collected. The BM core biopsy length (in mm), crush artifact, and adequacy of the BMA&B were assessed by a pathologist blinded for randomization. The provider convenience with both techniques were collected from the operators prior to the availability of results. **Results:** There were no significant demographic differences between the 2 groups (OnControl vs Jamshidi, respectively). The median age was 65.5 (37-79) vs 63 (35-81) years. Overall, 50% of patients were male, and 35% were black. 91% had a prior BMA&B within the last 2 years (65.9% had 2-4 prior BMA&B and 83.5% had a prior OnControl drill experience). 31% had chronic pain. 38% had lytic lesions, 6% had osteoporosis, 5% had osteopenia and 31% were on active bisphosphonates. 22% had compression fractures and 11% had a prior h/o kyphoplasty. 26% (11% vs 15%, p=0.247) had inadequate sampling - unsuccessful core biopsy (1% vs 4%, p=0.181), aspiration artifact (3% vs 2%, p=0.530), cortical bone only (3% vs 3%, p=0.631) and hemodiluted specimen (5% vs 6%, p=0.575) but were not statistically different between 2 groups. The core length was significantly longer for the OnControl [14 (5-30) vs 9.5 (3-23) mm, p=0.003]. The time for procedure was significantly shorter for OnControl [7 (3-24) vs 10.5 (4-30) minutes, p=0.06]. There were no differences observed between the 2 groups in terms of pain post procedure, or the impact of pain. Operator assessment unanimously favored the use of OnControl device. On a scale of 1-10 (1 being the least inconvenient and 10 the most convenient), median operator convenience for OnControl vs Jamshidi was 10 (range, 9-10) vs 3 (range, 2-7), p< 0.001. **Conclusions:** The OnControl system was associated with less procedural time and a better core biopsy without increased incidence of crush artifact. The robust size of the core biopsy may negate the need for repeat procedures. The operators favored the use of OnControl device over a manually exhausting Jamshidi needle for BMA&B.

Association between dexamethasone exposure and visually significant cataracts in myeloma

Rahul Banerjee[1], Jorge Arturo Hurtado Martinez[2], Patricia Alejandra Flores Pérez[2], Nolan Porras[2], Jay Hydren[2], Jennifer Ahlstrom[2], Andrew Cowan[3]

[1]Fred Hutchinson Cancer Center; [2]HealthTree Foundation; [3]University of Washington, Seattle, WA, USA

Introduction: Ocular comorbidities such as cataracts, which may lead to blurry vision and QOL impairments, are more common in relapsed multiple myeloma (MM) than in new diagnoses (Ailawadhi 2022). Pre-belantamab ophthalmological analyses from DREAMM-2 [3+ prior lines of therapy (LoT), over half aged ≥65] showed that 60% of pts with relapsed/refractory MM had cataracts at baseline (Popat 2022). In contrast, only 34% of US adults aged ≥65 have cataracts (Wittenborn 2023). We hypothesized that dexamethasone (dex) dose intensity and duration would predict both cataract occurrence as well as visual significance (pt-reported interference with QOL). **Methods:** This was a secondary analysis of pt-reported treatment data collected from users of the HealthTree Cure Hub for Multiple Myeloma database. Pts who recalled developing cataracts with any LoT were asked to rate their cataract-related symptoms on a 1-5 Likert scale. Dex exposure was assessed by calculating the total duration and dosage across all LoTs until cataracts were first reported; cycles were assumed to be 28 days long regardless of regimen. Time-to-cataract survival analyses were conducted to assess the risk of cataracts. Ordinal logistic regression and correlation analyses were performed to evaluate the association between dex exposure and cataract severity. **Results:** Of n=231 pts with MM who recalled developing cataracts, median age at cataract onset was 65 years (range 31-85) with median 23 prior dex cycles (IQR: 3.5-33.3). Of these pts, 36% developed cataracts within 6 cycles of dex and 48% within 12 cycles of dex. Cataract severity (on a 1-5

44% of pts in both categories resort to using their personal savings to cover healthcare costs. **Conclusions:** This survey highlighted the critical roles of healthcare teams and online patient advocacy groups in educating and empowering NDMM and RRMM pts, becoming increasingly important resources over time. MM mainly impacts exercise, the ability to do their favorite things, mental health, and finances, particularly in RRMM pts. Financial strain may have led to using personal savings for medical expenses. These findings underscore the importance of education, empowerment, and comprehensive support in addressing the physical and financial aspects of MM patient care.

Introduction: Bone marrow aspiration and biopsies (BMA&B) provide diagnostic and prognostic information in patients with plasma cell disorders. The use of Jamshidi needle for manual BMA&B has been the established method of choice. Powered biopsy devices (OnControl) are gaining popularity due to shorter procedural time and operator convenience, but are limited by increased incidence of crush artifact and inadequate sampling. We performed a prospective randomized control trial (RCT) to assess the quality of BMA&B and the patient and provider convenience. **Methods:** Adult patients with plasma cell disorders undergoing BMA&B were consented by nine operators who are familiar with both techniques. A total of 100 patients underwent randomization to receive BMA&B by OnControl drill vs manual Jamshidi needle. A questionnaire was used to assess the intensity of pain and the impact of BMA&B on general activity, work, and sleep at baseline and on days 1, 3 and 7. Sedation information, time for completion of procedure, and demographic data were collected. The BM core biopsy length (in mm), crush artifact, and adequacy of the BMA&B were assessed by a pathologist blinded for randomization. The provider convenience with both techniques were collected from the operators prior to the availability of results. **Results:** There were no significant demographic differences between the 2 groups (OnControl vs Jamshidi, respectively). The median age was 65.5 (37-79) vs 63 (35-81) years. Overall, 50% of patients were male, and 35% were black. 91% had a prior BMA&B within the last 2 years (65.9% had 2-4 prior BMA&B and 83.5% had a prior OnControl drill experience). 31% had chronic pain. 38% had lytic lesions, 6% had osteoporosis, 5% had osteopenia and 31% were on active bisphosphonates. 22% had compression fractures and 11% had a prior h/o kyphoplasty. 26% (11% vs 15%, p=0.247) had inadequate sampling - unsuccessful core biopsy (1% vs 4%, p=0.181), aspiration artifact (3% vs 2%, p=0.530), cortical bone only (3% vs 3%, p=0.631) and hemodiluted specimen (5% vs 6%, p=0.575) but were not statistically different between 2 groups. The core length was significantly longer for the OnControl [14 (5-30) vs 9.5 (3-23) mm, p=0.003]. The time for procedure was significantly shorter for OnControl [7 (3-24) vs 10.5 (4-30) minutes, p=0.06]. There were no differences observed between the 2 groups in terms of pain post procedure, or the impact of pain. Operator assessment unanimously favored the use of OnControl device. On a scale of 1-10 (1 being the least inconvenient and 10 the most convenient), median operator convenience for OnControl vs Jamshidi was 10 (range, 9-10) vs 3 (range, 2-7), p< 0.001. **Conclusions:** The OnControl system was associated with less procedural time and a better core biopsy without increased incidence of crush artifact. The robust size of the core biopsy may negate the need for repeat procedures. The operators favored the use of OnControl device over a manually exhausting Jamshidi needle for BMA&B.

Association between dexamethasone exposure and visually significant cataracts in myeloma

Rahul Banerjee[1], Jorge Arturo Hurtado Martinez[2], Patricia Alejandra Flores Pérez[2], Nolan Porras[2], Jay Hydren[2], Jennifer Ahlstrom[2], Andrew Cowan[3]

[1]Fred Hutchinson Cancer Center; [2]HealthTree Foundation; [3]University of Washington, Seattle, WA, USA

Introduction: Ocular comorbidities such as cataracts, which may lead to blurry vision and QOL impairments, are more common in relapsed multiple myeloma (MM) than in new diagnoses (Ailawadhi 2022). Pre-belantamab ophthalmological analyses from DREAMM-2 [3+ prior lines of therapy (LoT), over half aged ≥65] showed that 60% of pts with relapsed/refractory MM had cataracts at baseline (Popat 2022). In contrast, only 34% of US adults aged ≥65 have cataracts (Wittenborn 2023). We hypothesized that dexamethasone (dex) dose intensity and duration would predict both cataract occurrence as well as visual significance (pt-reported interference with QOL). **Methods:** This was a secondary analysis of pt-reported treatment data collected from users of the HealthTree Cure Hub for Multiple Myeloma database. Pts who recalled developing cataracts with any LoT were asked to rate their cataract-related symptoms on a 1-5 Likert scale. Dex exposure was assessed by calculating the total duration and dosage across all LoTs until cataracts were first reported; cycles were assumed to be 28 days long regardless of regimen. Time-to-cataract survival analyses were conducted to assess the risk of cataracts. Ordinal logistic regression and correlation analyses were performed to evaluate the association between dex exposure and cataract severity. **Results:** Of n=231 pts with MM who recalled developing cataracts, median age at cataract onset was 65 years (range 31-85) with median 23 prior dex cycles (IQR: 3.5-33.3). Of these pts, 36% developed cataracts within 6 cycles of dex and 48% within 12 cycles of dex. Cataract severity (on a 1-5

Likert scale) was rated as hardly noticeable by 23%, uncomfortable by 29%, disruptive by 36%, severely disruptive by 11%, and requiring treatment discontinuation by 1%. Ordinal regression analyses of 97/231 pts with detailed dex dosing data available (from concurrent chart review) showed a significant association between total dex exposure and cataract severity (coefficient estimate [ce] 0.255, p< 0.05), which was confirmed by correlation analysis (r=0.143). However, age at cataract onset (ce 0.004, p=0.81) and dex dose per cycle (ce -0.004, p=0.19) did not show a significant relationship with cataract severity. **Conclusions:** Of pts with MM who develop cataracts, almost half rate their cataracts as disruptive or severely disruptive to QOL. Over 30% of pts who report cataracts recall developing this toxicity within 6 months of exposure to dex-containing regimens, a concerning finding given that pts may remain on dex for years with regimens like Dara-Kd or Isa-Kd in the relapsed setting. While limited by recall bias and lack of a control group who did not develop cataracts, strengths of our analysis include its direct focus on the pt experience. Given the unclear contribution of dex to most MM regimens apart from preventing infusion reactions during the 1st cycle, discontinuation of chronic dex after the first few cycles should be considered in all pts with MM and not just for frail or late-line pts.

Financial toxicity and time toxicity among patients with multiple myeloma

Rahul Banerjee[1], Andrew Cowan[2], Marivel Chavez-Ortega[1], Paul Carpenter[1], Masumi Oshima[1], Rachel Salit[1], Phuong Vo[1], Catherine Lee[1], Rohtesh Mehta[1], Veena Shankaran[1], Stephanie Lee[1], Christopher Su[1]

[1]Fred Hutchinson Cancer Center; [2]University of Washington, Seattle, WA, USA

Introduction: Multiple myeloma (MM) patients (pts) may be at ongoing risk of financial toxicity (FinTox) from medication costs and lost productivity. Similarly, "time toxicity" (TimeTox) from frequent healthcare interactions may persist into the maintenance phase of therapy. We aimed to characterize FinTox and TimeTox among patients with MM. **Methods:** We conducted a cross-sectional survey (mail and online) of MM pts who had undergone autologous stem cell transplantation (ASCT) at one American institution. Questions included the validated COST FinTox inventory, questions about financial fragility (e.g., difficulty with unexpected medical expenses), frequency/nature of healthcare interactions, and symptoms (PROMIS-29). FinTox was defined as COST score in the lowest quartile (≤25 in our cohort). After discussions with content experts and local pts with MM, we defined TimeTox as (a) MM-related healthcare interactions (including telehealth & phone calls) averaging ≥1x per week and/or (b) in-person MM-related interactions averaging ≥1x per month with each interaction requiring 4+ hours away from home including transit. For FinTox and TimeTox, multivariate logistic regression were performed using age, post-transplant years, caregiver status, insurance, income, and MM status (observation vs maintenance vs relapsed) as covariates. **Results:** Of 576 eligible pts, 205 (36%) completed the survey. Most (62%) were on maintenance, 22% on observation, and 16% on treatment for relapsed MM. Median age was 68 years (IQR 63-72), median time since ASCT 3 years (IQR 1-5), and median COST score 31 (IQR 25-37). 24% (n=50) were FinTox+, 39% (n=79) TimeTox+, and 12% (n=24) both. FinTox+ was reported by 26% of pts on observation, 32% of pts on maintenance, and 23% of relapsed pts. Of 79 TimeTox+ pts, 58% reported any-type MM interactions ≥1x weekly, 25% reported in-person MM visits ≥1x monthly with long transit times, and 16% both. TimeTox+ was reported by 11% of pts on observation, 35% of pts on maintenance, and 87% of relapsed pts. In univariate analyses, FinTox+ was associated with increased anxiety, depression, and fatigue (p< 0.01 in all cases), while TimeTox+ was associated with increased fatigue (p=0.01). FinTox+ was associated with skipping essential items/medications and financial fragility. In multivariate analyses, predictors of FinTox were younger age (OR=1.09, p=0.01) and income below $50K (OR=3.43, p< 0.01). The only predictor of TimeTox was relapsed status (OR=8.85, p< 0.01). **Conclusions:** In our study of over 200 pts, 24% were FinTox+ (regardless of disease status) and 39% TimeTox+. FinTox+ was associated with increased symptom burden and financial fragility, and better support of out-of-pocket costs through post-ASCT maintenance and relapse may be helpful. TimeTox+ was reported by over a third of pts on maintenance, and de-escalation of low-yield monitoring during this phase of survivorship should be considered. To our knowledge, this is the largest study to date of FinTox and TimeTox in MM.

Randomized phase II study of digital life coaching during stem cell transplantation for myeloma

Rahul Banerjee[1], Chiung-Yu Huang[2], Chloe Ryan[3], Albert Lee[4], Kelly Brassil[5], Jasmine Moore[5], Shagun Arora[2], Alfred Chung[2], Sandy Wong[2], Jeffrey Wolf[2], Thomas Martin[2], Anand Dhruva[2], Nina Shah[6]

[1]Fred Hutchinson Cancer Center; [2]University of California, San Francisco, CA, USA; [3]National Marrow Donor Program; [4]UCSD; [5]Pack Health; [6]AstraZeneca

Introduction: Autologous stem cell transplantation (ASCT) for multiple myeloma (MM) is associated with quality of life (QOL) impairments that may lead to long-term psychosocial issues or premature workforce retirement. Our pilot study previously demonstrated the feasibility of digital life coaching (DLC), whereby certified coaches work with patients via phone/text to provide wellness-related support during the peri-ASCT period. We now report the results of a randomized Phase II trial of DLC (clinicaltrials.gov ID NCT04589286) in this population. **Methods:** English-speaking patients with MM who owned cellphones were randomized to wellness handouts (control) versus an additional 16-week coaching subscription (DLC) beginning at Day -10. Endpoints included benzodiazepine or zolpidem-drug (B/Z) medication use, physical/mental QOL (PROMIS Global Health), distress (Distress Thermometer), insomnia (PROMIS Sleep Disturbances 4A), and

Likert scale) was rated as hardly noticeable by 23%, uncomfortable by 29%, disruptive by 36%, severely disruptive by 11%, and requiring treatment discontinuation by 1%. Ordinal regression analyses of 97/231 pts with detailed dex dosing data available (from concurrent chart review) showed a significant association between total dex exposure and cataract severity (coefficient estimate [ce] 0.255, p< 0.05), which was confirmed by correlation analysis (r=0.143). However, age at cataract onset (ce 0.004, p=0.81) and dex dose per cycle (ce -0.004, p=0.19) did not show a significant relationship with cataract severity. **Conclusions:** Of pts with MM who develop cataracts, almost half rate their cataracts as disruptive or severely disruptive to QOL. Over 30% of pts who report cataracts recall developing this toxicity within 6 months of exposure to dex-containing regimens, a concerning finding given that pts may remain on dex for years with regimens like Dara-Kd or Isa-Kd in the relapsed setting. While limited by recall bias and lack of a control group who did not develop cataracts, strengths of our analysis include its direct focus on the pt experience. Given the unclear contribution of dex to most MM regimens apart from preventing infusion reactions during the 1st cycle, discontinuation of chronic dex after the first few cycles should be considered in all pts with MM and not just for frail or late-line pts.

Randomized phase II study of digital life coaching during stem cell transplantation for myeloma

Rahul Banerjee[1], Chiung-Yu Huang[2], Chloe Ryan[3], Albert Lee[4], Kelly Brassil[5], Jasmine Moore[5], Shagun Arora[2], Alfred Chung[2], Sandy Wong[2], Jeffrey Wolf[2], Thomas Martin[2], Anand Dhruva[2], Nina Shah[6]

[1]Fred Hutchinson Cancer Center; [2]University of California, San Francisco, CA, USA; [3]National Marrow Donor Program; [4]UCSD; [5]Pack Health; [6]AstraZeneca

Introduction: Autologous stem cell transplantation (ASCT) for multiple myeloma (MM) is associated with quality of life (QOL) impairments that may lead to long-term psychosocial issues or premature workforce retirement. Our pilot study previously demonstrated the feasibility of digital life coaching (DLC), whereby certified coaches work with patients via phone/text to provide wellness-related support during the peri-ASCT period. We now report the results of a randomized Phase II trial of DLC (clinicaltrials.gov ID NCT04589286) in this population. **Methods:** English-speaking patients with MM who owned cellphones were randomized to wellness handouts (control) versus an additional 16-week coaching subscription (DLC) beginning at Day -10. Endpoints included benzodiazepine or zolpidem-drug (B/Z) medication use, physical/mental QOL (PROMIS Global Health), distress (Distress Thermometer), insomnia (PROMIS Sleep Disturbances 4A), and

Likert scales regarding study interventions. Linear mixed-effect modeling (LMM) was used to compare patient-reported endpoints. **Results:** Due to uneven rates of post-enrollment ASCT deferrals, 50 patients (coaching n = 21, control n = 29) were evaluable. Baseline characteristics, B/Z use, mental QOL, and insomnia were similar between arms apart from age (medians 68 in the DLC arm vs 61 in the control arm, p< 0.01). Physical QOL was improved with coaching (mean LMM difference +4.9, 95% CI +2.0 to +7.9); 86% versus 67% of patients achieved a meaningful physical QOL improvement at study conclusion compared to engraftment (≥5 points). Distress was borderline improved as well (mean LMM difference -0.7 points, 95% CI -1.6 to +0.1); for example, 10% (DLC) versus 28% (control) reported elevated distress (≥4) at the final assessment. Net Promoter Scores (with positive scores indicating high perceived value by patients) were -16% for handouts and +6% for DLC. **Conclusions:** Although limited by underpowering and global reductions in B/Z use compared to our historical data, our study demonstrated that DLC during ASCT was associated with improved physical QOL and a clear trend toward lower levels of distress. Future investigations of DLC in other oncologic settings, including relapsed MM, are under way.

Patients views on the relevance of quality of life (QoL) questionnaires commonly applied to evaluate the QoL of patients with AL amyloidosis

Sotirios Bristogiannis[1], Jahanzaib Khwaja[2], Darren Foard[3], Sarah Worthington[2], Yadanar Lwin[4], Joshua Bomsztyk[2], Sosana Delimpasi[1], Ayesha Shameem Mahmood[3], Brendan Wisniowski[3], Ashutosh Wechelaker[3], Charalampia Kyriakou[2]

[1]Evangelismos General Hospital, Athens, Greece; [2]NHS University College London Hospital, London, United Kingdom; [3]National Amyloidosis Centre, University College London, London, United Kingdom; [4]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Introduction: Systemic AL Amyloidosis remains an incurable disease despite the treatment advances that have considerably prolonged patients' survival. Optimizing patients' QoL impacted by both the disease and the treatment is a fundamental objective. Several non disease- specific QoL Questionnaires (QLQs), either generic or applied for similar diseases, are used in clinical and research practice. The aim of this study was to evaluate the relevance of the content of these QLQs to the actual QoL issues of patients with AL amyloidosis. **Methods:** Patients followed at the National Amyloidosis Centre (UK), were asked to complete the online survey assessing the relevance of 257 questions from the internationally commonly used QLQs (SF-36; PROMIS-GH; PROMIS-29 Profile; EORTC QLQ-C30; EQ-5D; EORTC-QLQ-MY20; MDASI-MM; FACT-BMT; FACIT-COST; FACT-GOG NTx; FACT-G; HPRSS; WPAI; KCCQ-12; DT; SWLS; STAI-Y; CSI; CESD; NPRS; MIH-13; CARG-GA) to their QoL. Patient demographics, disease and treatment characteristics were collected. The relevance of each question of the QLQs were graded using the 5-point Likert scale: not relevant, slightly relevant, relevant, fairly relevant, and very relevant. Analyses were performed for (I) 'not relevant' versus 'very relevant' questions and further (II) the 'non relevant' + 'slightly relevant' versus 'fairly relevant' +'very relevant'. Relevance was defined as agreement ≥ 50% between respondents. **Results:** 153 patients of various ages, ethnicities, time from diagnosis and on different treatment regimens completed the survey. Only 8 questions were graded as very relevant for the entire cohort that referred to two issues: tolerance to strenuous physical activity and family support. Sub-analysis of the responses, revealed 55 further relevant questions in stage II that referred to 7 additional QoL aspects: (i) Physical Limitation to Moderate Activity secondary to fatigue and/or fluid retention; Limitations of the (ii) Working capacity (iii)Family role (iii) Social Role and (iv) Leisure activities; (v) Sleep quality;(vi) Sensory/ Autonomic neuropathy; (vii) Family/ Emotional support. Nonetheless, work and family role restrictions were considered by more than half of the patients as not at all relevant in DT. Similarly, patients' views were divided in stage II of the analysis for 76 questions with some referring to the above seven issues in different wording but quite a few referring to pain, cognition, gastrointestinal manifestations and sexual life. **Conclusions:** This survey confirms the lack of an existing reliable QLQ to reflect the AL Amyloidosis patients' real daily QoL issues. The survey has identified some very relevant disease-specific issues that should be considered in the development of the core module. Further analysis is required for determining issues relevant to certain disease subgroups and proper question wording.

P-455

Survey of multiple myeloma (MM) patients and healthcare professionals (HCPs) on the relevance of existing health quality-of-life (QoL) questionnaires (QoLQ) to real-world QoL issues of MM patients

Sotirios Bristogiannis[1], Catherine SY. Lecat[2], Dipal Mehta[2], Jahanzaib Khwaja[2], Yadanar Lwin[3], Emma Dowling[2], Nuno Correia[2], Kate Xu[2], Annabel McMillan[2], Neil Rabin[2], Jonathan Sive[2], Rakesh Popat[2], Xenofon Papanikolaou[2], Lydia Lee[2], Kwee Yong[2], Sosana Delimpasi[1], Charalampia Kyriakou[2]

[1]Evangelismos General Hospital, Athens, Greece; [2]NHS University College London Hospital, London, United Kingdom; [3]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Introduction: Treatment advances have improved the survival of MM patients. Optimizing QoL has become a priority and there is a need for a representative updated QoL Questionnaire (QoLQ) since the validity of the existing ones is debated. The aim of this study was to evaluate the relevance of these QLQs and identify the real-life QoL issues of MM patients. **Methods:** MM patients and Healthcare professionals (HCPs) at University College London Hospital (UK) were asked to complete online surveys assessing the relevance of 172 questions from QoLQs that are commonly used for MM patients internationally (EORTC QLQ-C30, EORTC QLQ-MY20, EORTC QLQ-CIPN20, EQ-5D-3L, FACT-G, FACT-N; FACT-MM, FACIT-F, FACT-BMT) to patients' QoL.

Likert scales regarding study interventions. Linear mixed-effect modeling (LMM) was used to compare patient-reported endpoints. **Results:** Due to uneven rates of post-enrollment ASCT deferrals, 50 patients (coaching n = 21, control n = 29) were evaluable. Baseline characteristics, B/Z use, mental QOL, and insomnia were similar between arms apart from age (medians 68 in the DLC arm vs 61 in the control arm, p< 0.01). Physical QOL was improved with coaching (mean LMM difference +4.9, 95% CI +2.0 to +7.9); 86% versus 67% of patients achieved a meaningful physical QOL improvement at study conclusion compared to engraftment (≥5 points). Distress was borderline improved as well (mean LMM difference -0.7 points, 95% CI -1.6 to +0.1); for example, 10% (DLC) versus 28% (control) reported elevated distress (≥4) at the final assessment. Net Promoter Scores (with positive scores indicating high perceived value by patients) were -16% for handouts and +6% for DLC. **Conclusions:** Although limited by underpowering and global reductions in B/Z use compared to our historical data, our study demonstrated that DLC during ASCT was associated with improved physical QOL and a clear trend toward lower levels of distress. Future investigations of DLC in other oncologic settings, including relapsed MM, are under way.

Patients views on the relevance of quality of life (QoL) questionnaires commonly applied to evaluate the QoL of patients with AL amyloidosis

Sotirios Bristogiannis[1], Jahanzaib Khwaja[2], Darren Foard[3], Sarah Worthington[2], Yadanar Lwin[4], Joshua Bomsztyk[2], Sosana Delimpasi[1], Ayesha Shameem Mahmood[3], Brendan Wisniowski[3], Ashutosh Wechelaker[3], Charalampia Kyriakou[2]

[1]Evangelismos General Hospital, Athens, Greece; [2]NHS University College London Hospital, London, United Kingdom; [3]National Amyloidosis Centre, University College London, London, United Kingdom; [4]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Introduction: Systemic AL Amyloidosis remains an incurable disease despite the treatment advances that have considerably prolonged patients' survival. Optimizing patients' QoL impacted by both the disease and the treatment is a fundamental objective. Several non disease- specific QoL Questionnaires (QLQs), either generic or applied for similar diseases, are used in clinical and research practice. The aim of this study was to evaluate the relevance of the content of these QLQs to the actual QoL issues of patients with AL amyloidosis. **Methods:** Patients followed at the National Amyloidosis Centre (UK), were asked to complete the online survey assessing the relevance of 257 questions from the internationally commonly used QLQs (SF-36; PROMIS-GH; PROMIS-29 Profile; EORTC QLQ-C30; EQ-5D; EORTC-QLQ-MY20; MDASI-MM; FACT-BMT; FACIT-COST; FACT-GOG NTx; FACT-G; HPRSS; WPAI; KCCQ-12; DT; SWLS; STAI-Y; CSI; CESD; NPRS; MIH-13; CARG-GA) to their QoL. Patient demographics, disease and treatment characteristics were collected. The relevance of each question of the QLQs were graded using the 5-point Likert scale: not relevant, slightly relevant, relevant, fairly relevant, and very relevant. Analyses were performed for (I) 'not relevant' versus 'very relevant' questions and further (II) the 'non relevant' + 'slightly relevant' versus 'fairly relevant' +'very relevant'. Relevance was defined as agreement ≥ 50% between respondents. **Results:** 153 patients of various ages, ethnicities, time from diagnosis and on different treatment regimens completed the survey. Only 8 questions were graded as very relevant for the entire cohort that referred to two issues: tolerance to strenuous physical activity and family support. Sub-analysis of the responses, revealed 55 further relevant questions in stage II that referred to 7 additional QoL aspects: (i) Physical Limitation to Moderate Activity secondary to fatigue and/or fluid retention; Limitations of the (ii) Working capacity (iii)Family role (iii) Social Role and (iv) Leisure activities; (v) Sleep quality;(vi) Sensory/ Autonomic neuropathy; (vii) Family/ Emotional support. Nonetheless, work and family role restrictions were considered by more than half of the patients as not at all relevant in DT. Similarly, patients' views were divided in stage II of the analysis for 76 questions with some referring to the above seven issues in different wording but quite a few referring to pain, cognition, gastrointestinal manifestations and sexual life. **Conclusions:** This survey confirms the lack of an existing reliable QLQ to reflect the AL Amyloidosis patients' real daily QoL issues. The survey has identified some very relevant disease-specific issues that should be considered in the development of the core module. Further analysis is required for determining issues relevant to certain disease subgroups and proper question wording.

Survey of multiple myeloma (MM) patients and healthcare professionals (HCPs) on the relevance of existing health quality-of-life (QoL) questionnaires (QoLQ) to real-world QoL issues of MM patients

Sotirios Bristogiannis[1], Catherine SY. Lecat[2], Dipal Mehta[2], Jahanzaib Khwaja[2], Yadanar Lwin[3], Emma Dowling[2], Nuno Correia[2], Kate Xu[2], Annabel McMillan[2], Neil Rabin[2], Jonathan Sive[2], Rakesh Popat[2], Xenofon Papanikolaou[2], Lydia Lee[2], Kwee Yong[2], Sosana Delimpasi[1], Charalampia Kyriakou[2]

[1]Evangelismos General Hospital, Athens, Greece; [2]NHS University College London Hospital, London, United Kingdom; [3]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Introduction: Treatment advances have improved the survival of MM patients. Optimizing QoL has become a priority and there is a need for a representative updated QoL Questionnaire (QoLQ) since the validity of the existing ones is debated. The aim of this study was to evaluate the relevance of these QLQs and identify the real-life QoL issues of MM patients. **Methods:** MM patients and Healthcare professionals (HCPs) at University College London Hospital (UK) were asked to complete online surveys assessing the relevance of 172 questions from QoLQs that are commonly used for MM patients internationally (EORTC QLQ-C30, EORTC QLQ-MY20, EORTC QLQ-CIPN20, EQ-5D-3L, FACT-G, FACT-N; FACT-MM, FACIT-F, FACT-BMT) to patients' QoL.

Likert scales regarding study interventions. Linear mixed-effect modeling (LMM) was used to compare patient-reported endpoints. **Results:** Due to uneven rates of post-enrollment ASCT deferrals, 50 patients (coaching n = 21, control n = 29) were evaluable. Baseline characteristics, B/Z use, mental QOL, and insomnia were similar between arms apart from age (medians 68 in the DLC arm vs 61 in the control arm, p< 0.01). Physical QOL was improved with coaching (mean LMM difference +4.9, 95% CI +2.0 to +7.9); 86% versus 67% of patients achieved a meaningful physical QOL improvement at study conclusion compared to engraftment (≥5 points). Distress was borderline improved as well (mean LMM difference -0.7 points, 95% CI -1.6 to +0.1); for example, 10% (DLC) versus 28% (control) reported elevated distress (≥4) at the final assessment. Net Promoter Scores (with positive scores indicating high perceived value by patients) were -16% for handouts and +6% for DLC. **Conclusions:** Although limited by underpowering and global reductions in B/Z use compared to our historical data, our study demonstrated that DLC during ASCT was associated with improved physical QOL and a clear trend toward lower levels of distress. Future investigations of DLC in other oncologic settings, including relapsed MM, are under way.

Survey of multiple myeloma (MM) patients and healthcare professionals (HCPs) on the relevance of existing health quality-of-life (QoL) questionnaires (QoLQ) to real-world QoL issues of MM patients

Sotirios Bristogiannis[1], Catherine SY. Lecat[2], Dipal Mehta[2], Jahanzaib Khwaja[2], Yadanar Lwin[3], Emma Dowling[2], Nuno Correia[2], Kate Xu[2], Annabel McMillan[2], Neil Rabin[2], Jonathan Sive[2], Rakesh Popat[2], Xenofon Papanikolaou[2], Lydia Lee[2], Kwee Yong[2], Sosana Delimpasi[1], Charalampia Kyriakou[2]

[1]Evangelismos General Hospital, Athens, Greece; [2]NHS University College London Hospital, London, United Kingdom; [3]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Introduction: Treatment advances have improved the survival of MM patients. Optimizing QoL has become a priority and there is a need for a representative updated QoL Questionnaire (QoLQ) since the validity of the existing ones is debated. The aim of this study was to evaluate the relevance of these QLQs and identify the real-life QoL issues of MM patients. **Methods:** MM patients and Healthcare professionals (HCPs) at University College London Hospital (UK) were asked to complete online surveys assessing the relevance of 172 questions from QoLQs that are commonly used for MM patients internationally (EORTC QLQ-C30, EORTC QLQ-MY20, EORTC QLQ-CIPN20, EQ-5D-3L, FACT-G, FACT-N; FACT-MM, FACIT-F, FACT-BMT) to patients' QoL.

Demographics, disease and treatment characteristics were collected for each survey. The relevance of each question of the QoLQs was graded using the 5-point Likert scale: not relevant, slightly relevant, relevant, fairly relevant, and very relevant. HCPs' and patients' responses were analysed separately. MM patients' results were further stratified based on age, the presence of renal and bone disease. **Results:** 224 patients (M: 129, F: 89) of various ethnicities, disease duration and treatment history completed the survey. The 20 most 'relevant' questions for patients were related to functional well-being (cognition, working capacity, physical ability, leisure activities and sleep quality), emotional support from their environment (family, friends and HCPs) and disease sequelae (vulnerability to infections, appetite, pain). The majority of the most irrelevant questions referred to disease and treatment specific symptoms/signs (e.g. peripheral neuropathy, nausea). Of note, few patients regretted having a bone marrow transplant. Sub-group analysis by age identified minor differences: patients ≤70 years old reported additionally anxiety for their future and physical limitations due to the disease and its complications (neuropathy) whereas patients>70 years reported fatigue and did not consider mobility issues as relevant to MM. For renal and bone disease subgroups, limitations to strenuous activities and pain were significantly relevant. The bone disease group had higher anxiety for disease progression. For the 42 surveyed HCPs, the median weighted average per question was higher (3.12, range: 1.76-3.82) than that of patients (1.23, range: 0.54-2.94). HCPs graded fatigue, physical limitations, impact on usual roles (e.g. family, work), pain and neuropathy as more relevant compared to patient. Contrary to patients, effects of treatment (e.g. hair loss) were considered significant by HCPs. **Conclusions:** This survey highlighted significant differences between HCPs' and patients' views of QoL issues. It identified the significant areas that we would advocate to be included in a new disease QoLQ.

P-456

Survey on real world quality of life (QoL) issues relevant to distinct AL amyloidosis patient subgroups

Sotirios Bristogiannis[1], Jahanzaib Khwaja[2], Darren Foard[3], Sarah Worthington[2], Joshua Bomsztyk[3], Yadanar Lwin[4], Ayesha Shameem Mahmood[3], Sosana Delimpasi[5], Ashutosh Wechelaker[3], Charalampia Kyriakou[2]

[1]Evangelismos General Hospital, Athens, Greece; [2]NHS University College London Hospital, London, United Kingdom; [3]National Amyloidosis Centre, University College London, London, United Kingdom; [4]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [5]General Hospital Evangelismos, Athens, Greece

Introduction: Amyloidosis is a systemic disease, associated with multiorgan involvement with considerable disease and treatment-related morbidity. Therapeutic advances have improved survival and QoL is becoming a significant treatment decision-making factor. There is no validated specific QoL Questionnaire (QOLQ) for AL Amyloidosis. The aim of this survey was to identify the most relevant QoL issues to patients from the existing reported QoLQ. **Methods:** Patients with AL Amyloidosis, followed at the UK National Amyloidosis Centre, were invited to complete an online survey assessing the relevance of the total of 257 questions from the internationally commonly used QLQs to their QoL (SF-36; PROMIS-GH; PROMIS-29 Profile; EORTC QLQ-C30; EQ-5D; EORTC-QLQ-MY20; MDASI-MM; FACT-BMT; FACIT-COST; FACT-GOG NTx; FACT-G; HPRSS; WPAI; KCCQ-12; DT; SWLS; STAI-Y; CSI; CESD; NPRS; MIH-13; CARG-GA). Patient demographics, disease and treatment characteristics were collected. The relevance of each question of the QLQs were graded using the 5-point Likert scale (not relevant, slightly relevant, relevant, fairly relevant, very relevant). Relevance was defined as agreement ≥ 50% between respondents on the grading scale. The entire cohort identified Physical Limitation to Intense Activity and Family Support as the only common very relevant QoL issues. Sub-group analysis was based on age, disease duration (≤ 1y, 1-2 y, ≥2 to 4 y, ≥4 y), the presence of cardiac, renal and nerve involvement. **Results:** 153 patients (M: 88, F: 55) of various ethnicities and on different treatment regimens completed the survey. Both patient groups ≤ 70 yr. and reported significant physical decline,For the elderly, fatigue was also common, while for the younger sleep quality, family and emotional support were relevant, too Irrespective of their age, patients with neuropathy experienced pain and paresthesia, sought family and emotional support and were limited in the kind of work. Of these, those >70 yr, reported, limited social and leisure activities and suffered from heart failure. Patients diagnosed ≥2 yr reported, in contrast to those 70 y.o. suffered from peripheral edema and dry mouth. **Conclusions:** AL Amyloidosis manifests in a diverse and evolving manner. This patient survey identified the difference in relevance of some of the existing used QOL issues in the different patient subgroups. This stresses the need for the development of relevant QLQ that should capture the QOL issues of distinct patients subgroups to reliably guide treatment decision-making.

Waldenstrom's Macroglobulinaemia (WM) patients' online survey -currently available QoLQs not representative of real-world health quality-of-life (QoL) issues of WM patients

Sotirios Bristogiannis[1], Jahanzaib Khwaja[2], Ibrahim Tohidi-Esfahani[3], Nicole Japzon[2], David Young[4], Yadanar Lwin[5], Sosana Delimpasi[1], Shirley D'Sa[2], Judith Trotman[3], Charalampia Kyriakou[2]

[1]Evangelismos General Hospital, Athens, Greece; [2]NHS University College London Hospital, London, United Kingdom; [3]Concord Repatriation General Hospital, University of Sydney, Sydney, Australia; [4]WMozzies, Australian Affiliate Member of the International Waldenstrom's Macroglobulinaemia Foundation, Australia; [5]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Introduction: Waldenstrom's Macroglobulinaemia (WM) is an indolent lymphoproliferative disease with prolonged survival but recognised diverse range of disabling symptoms related to bone marrow burden and disease's immune manifestations. Literature

suggests that its QoL impact is imperfectly mirrored by the available QoL Questionnaires (QoLQ) and this was meant to be evaluated further in this study. **Methods:** Patients with WM followed up at the University College London Hospital (UK) or enrolled in the WMozzies' Registry (Australia), were asked to complete an online survey assessing the relevance to their QoL of a total of 412 questions from commonly used QoLQs internationally (EORTC QLQ-C30; EQ-5D-5L; FACT-G; FACIT-F; FACT-An; FACT-GOG/NTx; FACT-Lym; SF-36; HADS; DASS-21; QLACS; IES; FSS; IPA). Patient demographics, disease and treatment characteristics were collected. Patients graded the relevance of each question using the 5-point Likert scale: not relevant, slightly relevant, relevant, fairly relevant, and very relevant. Analysis was performed initially for (I) 'not relevant' versus 'very relevant' responses and further for (II) 'non relevant' + 'slightly relevant' versus 'fairly relevant' + 'very relevant'. Relevance was defined as agreement ≥50% between respondents on the grading scale. Percentage difference ≤10% between different grades was defined as non-significant. **Results:** 92 patients (M: 45, F: 47) of various ethnicities, disease duration and on different treatment regimens completed the survey. Only 1 question was very relevant for the entire cohort, which referred to family support. Of the remaining 398 questions: 59 were graded as not relevant, for 88 the views on their significance were divided and the rest were fairly relevant. In stage II of the analysis, 33 further relevant questions were identified that referred to fatigue, limitations of physical, social, leisure activities and occupation as well as to sleep quality, pain, emotional burden and family well-being. These were derived from several of the QoLQ, but primarily the FACT-G core module. Asymptomatic WM patients reported limits to their ability for moderate activities, their life enjoyment and anxiety for the future, so they seek emotional support from their environment. WM patients with peripheral neuropathy are often restricted to even light activities, often reported breathing difficulty and have neuropathic symptoms that cannot be reflected by existing QoLQs. Similarly, WM patients with cold agglutinin disease report limitations to even light exertion. Lastly, WM patients with B-symptoms report sleeping problems, considerable fatigue and concerns about their future that urges them to seek emotional support. **Conclusions:** This real-world patient survey showed that there is a lack of a representative QoLQ for WM. A new, disease specific QoLQ is needed that should take into account the QoL issues acknowledged in this survey by patients with various presentations of the disease.

The impact of continuous therapy on the quality of life in Romanian patients with multiple myeloma

Daniel Coriu[1], Sorina Nicoleta Badelita[1], Ruxandra Irimia[1], Sinziana Barbu[1], Loredana Cirlan[1], Larisa Zidaru[1], Andreea Jercan[1]

[1]*Fundeni Clinical Institute*

Introduction: The treatment paradigm of Multiple Myeloma (MM) has shifted in the past years, as continuous therapy is becoming the standard of care in both newly diagnosed as well as relapsed patients. Although it is undisputable that this approach has added a great benefit on the progression-free as well as overall survival, it is still unclear how the quality of life is impacted in these patients. **Methods:** The study includes 155 adult MM patients from Fundeni Clinical Institute in Romania, receiving continuous therapy containing Daratumumab, Proteasone Inhibitors, Immunomodulators or bi-specific antibodies. We developed a quantitative questionnaire to interrogate the effect of the therapy on their personal and professional life, their regard towards the therapy and to identify the side effects that have the strongest impact on their Quality of Life. **Results:** 80.6% of the patients reported that the treatment they are receiving negatively impacts their quality of life. More than half of the patients considered that the most detrimental aspects of the therapy are the financial burden, the impact on the professional life, and the inability of making plans for the future. 45.1% of the patients report that the therapy is negatively impacting their family life and over one third states that it has a deleterious effect on their relationship with their partner. One third of the patients also stated that the frequent visits to the hospital are causing them a medium-high level of anxiety. In terms of the side effects experienced, two-thirds of the patients consider that tiredness is the main factor causing a decrease in their quality of life, closely followed by the gastro-intestinal disturbances in half of the patients. Despite this, none of the patients considered dropping the therapy and more than half of the patients consider that the frequent visits to the hospital offer them a psychological comfort. In addition, 77.4% of the patients declare that they are afraid to stop the therapy if given the choice, the main concerns being the fear for an early relapse. **Conclusions:** Although continuous therapy is associated with a high financial burden and a negative impact on both the professional and personal life, the frequent visits to the hospital appear to be reassuring. Moreover, the patients would not opt for treatment discontinuation and feel safer when monitored frequently.

A randomized, controlled phase 2 trial of uproleselan, an e-selectin inhibitor, vs placebo to reduce GI toxicity in patients with multiple myeloma undergoing autologous hematopoietic cell transplant

Zachary Crees[1], Keith Stockerl-Goldstein[1], Meaghan Ryan[1], Feng Gao[1], Brandon Christen[1], Chris Mayeski[1], Michael Slade[1], Mark Schroeder[1], Ravi Vij[1], John DiPersio[1], Geoffrey Uy[1]

[1]*Washington University School of Medicine in St. Louis*

Introduction: High-dose Melphalan with autologous hematopoietic cell transplant (ASCT) plays a pivotal role in treating multiple myeloma (MM), but is associated with high rates of GI toxicity. Data suggest chemotherapy-initiated epithelial injury leads to inflammatory signaling and upregulation of the adhesion molecule, E-selectin, on vascular endothelium. This promotes inflammatory cell trafficking to sites of epithelial injury leading to further immune-mediated GI epithelial injury. Uproleselan (upro) is a synthetic, competitive E-selectin antagonist. Pre-clinical studies

suggests that its QoL impact is imperfectly mirrored by the available QoL Questionnaires (QoLQ) and this was meant to be evaluated further in this study. **Methods:** Patients with WM followed up at the University College London Hospital (UK) or enrolled in the WMozzies' Registry (Australia), were asked to complete an online survey assessing the relevance to their QoL of a total of 412 questions from commonly used QoLQs internationally (EORTC QLQ-C30; EQ-5D-5L; FACT-G; FACIT-F; FACT-An; FACT-GOG/NTx; FACT-Lym; SF-36; HADS; DASS-21; QLACS; IES; FSS; IPA). Patient demographics, disease and treatment characteristics were collected. Patients graded the relevance of each question using the 5-point Likert scale: not relevant, slightly relevant, relevant, fairly relevant, and very relevant. Analysis was performed initially for (I) 'not relevant' versus 'very relevant' responses and further for (II) 'non relevant' + 'slightly relevant' versus 'fairly relevant' + 'very relevant'. Relevance was defined as agreement ≥50% between respondents on the grading scale. Percentage difference ≤10% between different grades was defined as non-significant. **Results:** 92 patients (M: 45, F: 47) of various ethnicities, disease duration and on different treatment regimens completed the survey. Only 1 question was very relevant for the entire cohort, which referred to family support. Of the remaining 398 questions: 59 were graded as not relevant, for 88 the views on their significance were divided and the rest were fairly relevant. In stage II of the analysis, 33 further relevant questions were identified that referred to fatigue, limitations of physical, social, leisure activities and occupation as well as to sleep quality, pain, emotional burden and family well-being. Introduction: High-dose Melphalan with autologous hematopoietic cell transplant (ASCT) plays a pivotal role in treating multiple myeloma (MM), but is associated with high rates of GI toxicity. Data suggest chemotherapy-initiated epithelial injury leads to inflammatory signaling and upregulation of the adhesion molecule, E-selectin, on vascular endothelium. This promotes inflammatory cell trafficking to sites of epithelial injury leading to further immune-mediated GI epithelial injury. Uproleselan (upro) is a synthetic, competitive E-selectin antagonist. Pre-clinical studies

have shown upro+chemotherapy reduced GI toxicity in mice by blocking secondary migration of inflammatory macrophages to GI epithelium. Subsequent clinical trials evaluating upro+chemotherapy in AML showed reduced GI toxicities vs historical controls. **Methods:** This was a Phase 2, single-center, randomized, double-blind, placebo-controlled trial of patients undergoing melphalan-conditioned (200mg/m^2) ASCT for MM, randomized 1:1 to prophylactic upro+standard of care (SoC) vs placebo+SoC. The primary objective was to demonstrate superiority of upro+SoC to reduce mean diarrhea severity (CTCAE v5.0) during days 1-14 post-ASCT. Secondary endpoints included patient reported outcomes (PRO) of GI-related quality of life (QoL) (NCI PRO-CTCAE v1.0), Bristol Stool Scale (BSS), alternative GI toxicities and metrics of healthcare resource utilization. Exploratory sensitivity analyses of the primary endpoint evaluated diarrhea severity on days 1-10, 1-7 and 3-10 post-ASCT. Significance level of p< 0.2 was predefined for all endpoints. **Results:** Fifty adults with MM enrolled from 5/2021-10/2022. Demographics were similar across arms. Over days 1-14 post-ASCT, a lower mean diarrhea severity score (1.07 vs 1.19, 95% CI -0.28; 0.04, p=0.34) and lower incidence of >Grade 2 diarrhea (odds ratio [OR] 0.61, 95% CI 0.35; 1.07, p=0.26) were observed favoring upro+SoC, but neither met significance level of pGrade 2 diarrhea over those times were all significantly lower favoring upro+SoC (p=0.11, p=0.02 and p=0.14). Time to neutrophil engraftment and response rates were similar. **Conclusions:** In this randomized, controlled trial, upro+SoC prior to melphalan-conditioned ASCT in MM did not meet its primary endpoint but met key secondary endpoints of reduced >Grade 2 diarrhea, reduced severe diarrhea by BSS and improved patient reported QoL, vs placebo+SoC. Further studies are needed to verify these observations.

Evaluation of a precision-based exercise program for patients with multiple myeloma

Ulrike Dapunt[1], Pauline Ehret[1], Jean-Luc Paratte[2], Rea Kühl[2], Joachim Wiskemann[2], Carsten Müller-Tidow[3], Dirk Jäger[4], Marc Raab[5], Hartmut Goldschmidt[1]

[1]Internal Medicine V, GMMG-Study Group at University Hospital Heidelberg, Heidelberg, Germany; [2]Working Group Exercise Oncology, Department of Medical Oncology, National Center for Tumor Diseases (NCT), Heidelberg University; [3]Department of Hematology, Oncology and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany; National Center for Tumor Diseases (NCT), Heidelberg, Germany; [4]National Center for Tumor Diseases (NCT), Heidelberg University; [5]Dept. of Medicine V Hematology, Oncology and Rheumatology, University Hospital Heidelberg, Heidelberg, Germany

Introduction: Multiple Myeloma is often associated with severe loss of bone substance which might endanger stability of the skeletal system. Even though the benefits of regular physical exercise in cancer patients have been demonstrated in depth and patients frequently express interest in structured exercise programs, uncertainties regarding bone stability are of great concern to both patients and oncologic healthcare providers. Because of the heterogeneity of bone involvement, exercise programs should be tailored to individual clinical conditions and require an interdisciplinary assessment. **Methods:** Data of multiple myeloma patients (n=100) who received a precision-based exercise program (PEP) according to an orthopaedic evaluation of bone stability and individual physical fitness were analysed retrospectively. Bone stability was assessed by current whole-body CT-scan according to established scoring systems (Spinal Instability Neoplastic Score (SINS), Mirels' score). All patients with stable and unstable osteolyses received a PEP which included body awareness, stretching, coordination and muscle strength training at different levels. Subsequently, PEP was continued home-based supported by an exercise therapy mobile app or under 1:1 supervision led by a local physical therapist. Patients (n=91) were contacted for a follow-up interview. **Results:** Median age was 61.5 years (range: 27-83, IQR: 13) and the majority of patients (53%) asked for consultation on physical exercise during maintenance therapy. Whole body CT-scans showed multiple (>7) osteolytic lesions in most patients and in 60 % at least one osteolysis of the spine was considered potentially unstable or unstable according to SINS. 90% of patients already pursued some aerobic exercise and 24% resistance training. Following consultation on bone stability and a PEP-introductory session, the number of patients performing resistance training could be significantly increased (55% ≥2 sessions/week, 24% 1 session/week or intermittent, 21% no training). Musculoskeletal pain was reported frequently (31% mild, 36% moderate, 8% severe). At the follow-up interview, 75% of patients who performed PEP stated that painful symptoms could be effectively alleviated by exercise. Moreover, only patients that exercised regularly were able to discontinue pain medication. No injuries were reported in association with PEP. **Conclusions:** We were able to demonstrate that individualized resistance training is feasible and safe, even for patients with unstable bone lesions (SINS >12). By means of a precision-based exercise program, patients' self-efficacy in managing musculoskeletal pain was enhanced and pain medication could be reduced.

Patients (n=91) were contacted for a follow-up interview. **Results:** Median age was 61.5 years (range: 27-83, IQR: 13) and the majority of patients (53%) asked for consultation on physical exercise during maintenance therapy. Whole body CT-scans showed multiple (>7) osteolytic lesions in most patients and in 60 % at least one osteolysis of the spine was considered potentially unstable or unstable according to SINS. 90% of patients already pursued some aerobic exercise and 24% resistance training. Following consultation on bone stability and a PEP-introductory session, the number of patients performing resistance training could be significantly increased (55% ≥2 sessions/week, 24% 1 session/week or intermittent, 21% no training). Musculoskeletal pain was reported frequently (31% mild, 36% moderate, 8% severe). At the follow-up interview, 75% of patients who performed PEP stated that painful symptoms could be effectively alleviated by exercise. Moreover, only patients that exercised regularly were able to discontinue pain medication. No injuries were reported in association with PEP. **Conclusions:** We were able to demonstrate that individualized resistance training is feasible and safe, even for patients with unstable bone lesions (SINS >12). By means of a precision-based exercise program, patients' self-efficacy in managing musculoskeletal pain was enhanced and pain medication could be reduced.

An overview of challenges experienced in multiple myeloma: perspectives of hematologist-oncologists and specialist nurses

Faith Davies[1], Hayley Beer[2], Beth Faiman[3], Joseph Mikhael[4], J Blake Bartlett[5], Georgia Attfield[6], Tallulah Price[6], Maya Gilbert[6]

[1]Perlmutter Cancer Center, NYU Langone Health, New York, NY, USA; [2]Myeloma Australia & Peter MacCallum Cancer Centre; [3]Cleveland Clinic Taussig Cancer Institute, Department of Hematology and Medical Oncology; [4]Translational Genomics Research Institute (TGen), City of Hope Cancer Center; [5]Janssen Global Services LLC; [6]VMLY&R Health

Introduction: Multiple myeloma (MM) is a highly heterogeneous and incurable disease. Progress has been made to improve patient outcomes over recent years, but there is a need to better understand the challenges experienced by patients, to both improve the patient and carer experience, and support healthcare professionals (HCPs)

to optimize care. As a first step, this research aims to identify challenges experienced in MM from an HCP perspective. **Methods:** 1-hour in-depth, virtual, double-blind interviews were conducted between 09/13/22-11/09/22, with 18 hematologist-oncologists (hem-oncs) 44% of whom work in academic centers, and 4 specialist nurses, from 8 countries: US, UK, Spain, France, Germany, Italy, Japan, and Brazil. The interview questions covered 3 themes: the evolution and future of MM, the healthcare ecosystem, and perceived patient perspectives on current care. Key words were used to identify concepts discussed and quantify the qualitative data. Each interviewee discussed multiple concepts under each of the themes. **Results:** Of 18 hem-oncs interviewed, 56% (n=10) stated that treatment decisions were a major challenge in MM care, a challenge identified globally. 28% (n=5) of hem-oncs cited cost concerns and limited treatment availability as further exacerbating the challenge of treatment decision making, particularly within self-pay markets such as the US and Brazil. 44% (n=8) stated that staying up to date with research, including novel therapies, is of utmost importance to move the MM field closer to cure. 72% (n=13) of hem-oncs stated that availability, cost, and the logistics of MM treatment remain a key practical challenge in the effective delivery of MM care. Further to this, only 17% (n=3) of hem-oncs stated that managing quality-of-life (QoL) in MM patients was challenging for them. In contrast, when hem-oncs were asked about what they perceive to be the biggest challenges for patients, 50% (n=9) stated QoL, side effect management, and psychological wellbeing as most concerning. A sample of specialist nurses (n=4) were used to gain insight into areas of concern raised by MM patients during consultations. Cost and availability of treatment, logistical challenges of care, long waiting lists, and limited resources, including a lack of nurse time, were highlighted as overarching challenges, especially from EU countries. Other themes included delayed diagnosis, the need for multidisciplinary team input and improved access to supportive care. **Conclusions:** Many challenges have been identified in the management of MM, highlighting existing unmet needs in MM care for both patients and HCPs. There is a need to corroborate the findings of this research with MM patients to better understand challenges and gaps in care from a patient perspective. Further research combined with multi-stakeholder efforts are needed to address these challenges and support the holistic needs of patients and HCPs. One such ongoing initiative is the MM Call-to-Action.

Free light chain ratio over 100 and risk of hemodialysis in multiple myeloma

David Garrido[1], Cecibel Vasquez[1], Lucia Pérez Baliero[1], Eloísa Riva[2]

[1]Hospital de Clínicas; [2]Hospital Británico, Montevideo, Uruguay

Introduction: Acute kidney injury (AKI) is a major complication of multiple myeloma (MM), primarily attributed to the accumulation of immunoglobulin light chains (LC) in the distal nephron. **Objective:** The FLC ratio (FLCr, involved/non-involved) over 100 is a novel criterion for diagnosing active MM. Considering the effects of FLC on renal health, we aimed to analyze the risk of hemodialysis at MM diagnosis associated with an FLCr≥100. **Methods:** This observational, analytical, and retrospective study was conducted at the Hospital de Clínicas "Dr. Manuel Quintela" in Montevideo, Uruguay. We included adult (18 years) patients with newly diagnosed MM who did not have prior chronic kidney disease requiring dialysis. Patients with incomplete information regarding the evaluation of FLC and those with non-secretory MM were excluded. The standard methodology for sFLC evaluation was Freelite (The Binding Site). We calculated FLCr by dividing compromised FLC by non-compromised FLC. Dialysis risk was estimated using odds ratios, and medians were compared using non-parametric methods. We used SPSS and R for statistical analysis. **Results:** We included 74 patients, median age was 63 years (IQR 19.5), 55.4% were male. Regarding MM subtype, 62.2% had IgG, 20.3% had IgA, 16.2% had LC, and 1.3% had IgM. Risk stratification was represented as follows: ISS-1 (24.3%), ISS-2 (39.2%), ISS-3 (36.5%); RISS-1 (20%), RISS-2 (65%), and RISS-3 (15%). Median serum creatinine, hemoglobin, and serum calcium levels were 1.1 mg/dl (IQR 1.6), 9.2 g/dl (IQR 3.53), and 9.6 mg/dl (IQR 1.9), respectively. An FLCr ≥ 100 was observed in 23% of cases, with median values for FLCr, kappa chain, lambda chain, involved chain, and non-involved chain of 35.1 (IQR 91.9), 46.9 (IQR 475.5), 25.5 (IQR 325.8), 384 (IQR 1410.9), and 10.4 (IQR 18.1), respectively. Bortezomib-based regimens (BBR) were used in 59.5% of cases, and high-dose melphalan followed by autologous stem cell transplantation was used in 29.2% as consolidative therapy. The frequency of hemodialysis requirement at MM diagnosis was 14.9%, with 9.5% requiring chronic hemodialysis. The median serum creatinine for patients with FLCr≥100 was 1.6 (IQR 6.8), while for those with FLCr< 100 it was 1.0 (IQR 1.0) (p< 0.01). Additionally, the odds ratio for requiring hemodialysis at MM diagnosis in patients with FLCr≥100 was 9.3 (95% CI 2.8 to 37.7, p< 0.01). In a multivariate analysis including hemoglobin level, serum calcium, ISS, RISS, and age, FLCr≥100 was the only variable with a significant effect on the risk of hemodialysis OR 10.6 (95% CI 1.5 to 69.0, p=0.02). **Conclusions:** An FLCr≥100 is a strong risk factor for kidney injury and renal replacement requirement. However, given the limitations of the study design and sample size, our results need to be corroborated by further investigations.

P-463

Patient characteristics and burden in lenalidomide refractory multiple myeloma patients in Europe: a real-world survey

Francesca Gay[1], João Mendes[2], Emily Luke[3], Caspian Kluth[3], Phoebe Salmon[3], Abigail Bailey[3], Amanda Ribbands[3], Joaquín Martínez-López[4]

[1]Division of Hematology 1, Clinical trial unit AOU città della salute e della scienza, University of Torino; [2]Janssen-Cilag, Porto Salvo, Portugal; [3]Adelphi Real World, Bollington, UK; [4]Hematología Hospital 12 de Octubre, Madrid, Spain

Introduction: Lenalidomide (LEN) is the standard of care for Multiple Myeloma (MM) patients (pts), often given until progression. Progressive disease negatively impacts quality of life

(QoL), however real-world evidence in LEN refractory (Ref) pts is lacking. **Methods:** Data were drawn from the Adelphi MM Disease Specific Programme™, a cross-sectional survey with retrospective data completed by haematologists/haem-oncologists in Europe (France, Germany, Italy, Spain, and United Kingdom) from May-Nov 2021. Physicians completed patient record forms for their next 8 pts with a MM diagnosis, actively receiving treatment, and aligned to the following quota: 2x each of: first-line (1L) or second-line (2L), third-line (3L), fourth-line and beyond (4L+), and tri-exposed (exposed to a proteasome inhibitor, an immunomodulatory agent and an anti-CD38 targeted drug). Eligible pts voluntarily completed a questionnaire which included the EuroQol Visual Analogue Scale (EQ-VAS) [range: 0-1; 1 = best health] and European Organisation for Research and Treatment of Cancer (EORTC) QoL questionnaires (EORTC-QLQ-C30 and EORT-QLQ-MY20) [range: 0-100; 100 = best functioning / worst symptomology]. Bivariate comparisons were made between LEN and non-LEN Ref pts at time of data collection. LEN Ref is defined by the International Myeloma Working Group as progressive disease during LEN treatment or within 60 days of discontinuation. **Results:** 173 physicians provided data for 1,163 MM pts; 528 (45%) were LEN Ref, which had a higher mean [SD] age (71.9 [8.73] vs 70.4 [8.91] years; p=0.0058), were more likely to receive caregiver support (44% vs 36%, p=0.0082), experience bone lesions (70% vs 62%, p=0.0026) and more comorbidities vs non-LEN Ref pts (84% vs 78%, p=0.0248). Meaningful differences in employment status (p=0.0158) and Katz Activities of Daily Living (ADL) scores (p=0.008) were also observed, as 79% and 74% of LEN Ref and non-LEN Ref pts were retired, and 5% and 10% were in full/part-time work (respectively). 75% of LEN Ref pts and 82% of non-LEN Ref scored 5-6 (full independence) in the Katz ADL. Of pts that completed the questionnaire (n=248), 106 were LEN-Ref (46%) and had lower mean [SD] EQ-VAS scores (56.9 [17.86] vs 61.6 [16.83]; p=0.0326), reported more bone fractures (13% vs 2%, p=0.0017) and worse mean [SD] EORTC fatigue scores (49.6 [20.12] vs 43.5 [22.09], p=0.0280). The mean [SD] EORTC functioning score domains were 59.7 [23.40] vs 62.4 [22.25] (p=0.3501) for physical, 53.4 [26.01] vs 55.8 [27.67] (p=0.4928) for role, 69.8 [23.42] vs 72.9 [24.29] (p=0.3109) for cognitive, and 60.0 [25.5] vs 64.44 [27.45] (p=0.2028) for social, across LEN and non-LEN Ref pts respectively. **Conclusions:** This data shows that LEN Ref pts experience more bone lesions and frequent fractures, have less independence and report numerically inferior QoL compared to non-LEN Ref pts. There is an unmet need for new and innovative treatments that can reduce burden and improve QoL in LEN Ref pts.

P-464

Treatment decision-making in patients diagnosed with multiple myeloma

Doris Hansen[1], Todd Bixby[2], Karen Fixler[2], Lisa Shea[2], Christine Brittle[3], Kimberly Brunisholz[2], Yi-Hsuan Liu[2], Stephen Huo[2]

[1]Moffiitt Cancer Center; [2]Janssen Pharmaceuticals; [3]CorEvitas

Introduction: Shared decision-making is an important component in patient-centered healthcare, particularly for patients with multiple myeloma (MM) seeking individualized treatment options. In this study, we assessed how patients and caregivers make decisions related to stem-cell transplantation (SCT) and identified unmet needs in this process. **Methods:** Adult patients diagnosed with MM who received SCT within the past 5 years or their caregivers were recruited to participate in virtual structured 2-hour focus group discussions through involvement in a Patient Engagement Research Council focused on experiences with SCT. Discussions focused on information sources, patient understanding of SCT, conversations with doctors and families, and how these factors contributed to decision-making. **Results:** Discussions included 17 participants (14 patients, 3 caregivers). Approximately half of all participants (n=9, 53%) were < 60 years old, and 70% were female (n=12). Participants came from diverse racial/ethnic backgrounds (White, n=5; Black, n=6; other ethnic groups, n=6) and varied in educational experience (postgraduate, n=4; college graduate or some college, n=11; high school, n=2). Almost all participants learned about SCT from their oncologist or hematologist early in treatment planning, when SCT was presented as the expected treatment course. Although around half of the participants recalled initially having limited knowledge of SCT, many sought information from outside organizations (eg, foundations/societies, patient support groups); some received resources from their doctor. Key factors considered before deciding to proceed with SCT included long-term health impacts, side effects, and logistical or financial concerns. Participants spoke with their doctors about the SCT treatment process and potential risks and outcomes; family members were consulted regarding caregiving or logistical support needs. Decisions related to SCT were often made quickly; 2 patients made the decision on the day of diagnosis or within a few weeks. Approximately two-thirds of participants reported that they never considered, or were never offered, other treatment options. Participants recalled feeling nervous before their decision, followed by feelings of relief or hopefulness after deciding to undergo SCT. Four participants desired more information about the SCT process, particularly the recovery period, and 2 participants recalled feeling overwhelmed during decision-making. However, participants overall felt that they were adequately informed about SCT, and none regretted their decision to undergo SCT. **Conclusions:** Patients deciding to undergo SCT for MM drew on multiple information sources during the decision-making process but relied heavily on doctors' recommendations. Shared decision-making between patients, families, and providers—including education and discussion of alternative options and recovery—is important for patients facing a complex treatment process.

LEN Ref is defined by the International Myeloma Working Group as progressive disease during LEN treatment or within 60 days of discontinuation. **Results:** 173 physicians provided data for 1,163 MM pts; 528 (45%) were LEN Ref, which had a higher mean [SD] age (71.9 [8.73] vs 70.4 [8.91] years; p=0.0058), were more likely to receive caregiver support (44% vs 36%, p=0.0082), experience bone lesions (70% vs 62%, p=0.0026) and more comorbidities vs non-LEN Ref pts (84% vs 78%, p=0.0248). Meaningful differences in employment status (p=0.0158) and Katz Activities of Daily Living (ADL) scores (p=0.008) were also observed, as 79% and 74% of LEN Ref and non-LEN Ref pts were retired, and 5% and 10% were in full/part-time work (respectively). 75% of LEN Ref pts and 82% of non-LEN Ref scored 5-6 (full independence) in the Katz ADL. Of pts that completed the questionnaire (n=248), 106 were LEN-Ref (46%) and had lower mean [SD] EQ-VAS scores (56.9 [17.86] vs 61.6 [16.83]; p=0.0326), reported more bone fractures (13% vs 2%, p=0.0017) and worse mean [SD] EORTC fatigue scores (49.6 [20.12] vs 43.5 [22.09], p=0.0280). The mean [SD] EORTC functioning score domains were 59.7 [23.40] vs 62.4 [22.25] (p=0.3501) for physical, 53.4 [26.01] vs 55.8 [27.67] (p=0.4928) for role, 69.8 [23.42] vs 72.9 [24.29] (p=0.3109) for cognitive, and 60.0 [25.5] vs 64.44 [27.45] (p=0.2028) for social, across LEN and non-LEN Ref pts respectively. **Conclusions:** This data shows that LEN Ref pts experience more bone lesions and frequent fractures, have less independence and report numerically inferior QoL compared to non-LEN Ref pts. There is an unmet need for new and innovative treatments that can reduce burden and improve QoL in LEN Ref pts.

Treatment decision-making in patients diagnosed with multiple myeloma

Doris Hansen[1], Todd Bixby[2], Karen Fixler[2], Lisa Shea[2], Christine Brittle[3], Kimberly Brunisholz[2], Yi-Hsuan Liu[2], Stephen Huo[2]

[1]Moffiitt Cancer Center; [2]Janssen Pharmaceuticals; [3]CorEvitas

Introduction: Shared decision-making is an important component in patient-centered healthcare, particularly for patients with multiple myeloma (MM) seeking individualized treatment options. In this study, we assessed how patients and caregivers make decisions related to stem-cell transplantation (SCT) and identified unmet needs in this process. **Methods:** Adult patients diagnosed with MM who received SCT within the past 5 years or their caregivers were recruited to participate in virtual structured 2-hour focus group discussions through involvement in a Patient Engagement Research Council focused on experiences with SCT. Discussions focused on information sources, patient understanding of SCT, conversations with doctors and families, and how these factors contributed to decision-making. **Results:** Discussions included 17 participants (14 patients, 3 caregivers). Approximately half of all participants (n=9, 53%) were < 60 years old, and 70% were female (n=12). Participants came from diverse racial/ethnic backgrounds (White, n=5; Black, n=6; other ethnic groups, n=6) and varied in educational experience (postgraduate, n=4; college graduate or some college, n=11; high school, n=2). Almost all participants learned about SCT from their oncologist or hematologist early in treatment planning, when SCT was presented as the expected treatment course. Although around half of the participants recalled initially having limited knowledge of SCT, many sought information from outside organizations (eg, foundations/societies, patient support groups); some received resources from their doctor. Key factors considered before deciding to proceed with SCT included long-term health impacts, side effects, and logistical or financial concerns. Participants spoke with their doctors about the SCT treatment process and potential risks and outcomes; family members were consulted regarding caregiving or logistical support needs. Decisions related to SCT were often made quickly; 2 patients made the decision on the day of diagnosis or within a few weeks. Approximately two-thirds of participants reported that they never considered, or were never offered, other treatment options. Participants recalled feeling nervous before their decision, followed by feelings of relief or hopefulness after deciding to undergo SCT. Four participants desired more information about the SCT process, particularly the recovery period, and 2 participants recalled feeling overwhelmed during decision-making. However, participants overall felt that they were adequately informed about SCT, and none regretted their decision to undergo SCT. **Conclusions:** Patients deciding to undergo SCT for MM drew on multiple information sources during the decision-making process but relied heavily on doctors' recommendations. Shared decision-making between patients, families, and providers—including education and discussion of alternative options and recovery—is important for patients facing a complex treatment process.

Global disparities in multiple myeloma: examining adverse events and drug toxicity trends

Majid Jaberi-Douraki[1], Xuan Xu[1], Remya Ampadi Ramachandran[1], Beth Faiman[2], Faiz Anwer[2], Christy Samaras[2], Jim Riviere[1], Nuwan Indika Millagaha Gedara[1],

(QoL), however real-world evidence in LEN refractory (Ref) pts is lacking. **Methods:** Data were drawn from the Adelphi MM Disease Specific Programme™, a cross-sectional survey with retrospective data completed by haematologists/haem-oncologists in Europe (France, Germany, Italy, Spain, and United Kingdom) from May-Nov 2021. Physicians completed patient record forms for their next 8 pts with a MM diagnosis, actively receiving treatment, and aligned to the following quota: 2x each of: first-line (1L) or second-line (2L), third-line (3L), fourth-line and beyond (4L+), and tri-exposed (exposed to a proteasome inhibitor, an immunomodulatory agent and an anti-CD38 targeted drug). Eligible pts voluntarily completed a questionnaire which included the EuroQol Visual Analogue Scale (EQ-VAS) [range: 0-1; 1 = best health] and European Organisation for Research and Treatment of Cancer (EORTC) QoL questionnaires (EORTC-QLQ-C30 and EORT-QLQ-MY20) [range: 0-100; 100 = best functioning / worst symptomology]. Bivariate comparisons were made between LEN and non-LEN Ref pts at time of data collection. LEN Ref is defined by the International Myeloma Working Group as progressive disease during LEN treatment or within 60 days of discontinuation. **Results:** 173 physicians provided data for 1,163 MM pts; 528 (45%) were LEN Ref, which had a higher mean [SD] age (71.9 [8.73] vs 70.4 [8.91] years; p=0.0058), were more likely to receive caregiver support (44% vs 36%, p=0.0082), experience bone lesions (70% vs 62%, p=0.0026) and more comorbidities vs non-LEN Ref pts (84% vs 78%, p=0.0248). Meaningful differences in employment status (p=0.0158) and Katz Activities of Daily Living (ADL) scores (p=0.008) were also observed, as 79% and 74% of LEN Ref and non-LEN Ref pts were retired, and 5% and 10% were in full/part-time work (respectively). 75% of LEN Ref pts and 82% of non-LEN Ref scored 5-6 (full independence) in the Katz ADL. Introduction: Multiple myeloma (MM) is a complex hematologic malignancy with significant disparities in outcomes and treatment-related toxicities across different regions globally. This study aims to examine global disparities in adverse events and drug toxicity trends in MM and assess the impact of advances in MM regimens on mortality and hospitalization rates. **Methods:** A retrospective analysis was conducted using a large dataset from the Food and Drug Administration (FDA) Adverse Event Reporting System, a database maintained by the FDA that collects and analyzes information on adverse events. The dataset comprises 401,576 MM patients from North America (NA), Europe (EU), Asia (AS), Africa (AF), Oceania (OC), and Latin America & the Caribbean (LA), representing 129 countries and 27 phenotypic systems/organs categories. The dataset was curated to include patients' data from 2005 onwards. **Results:** The findings indicated a notable decrease in mortality and hospitalization rates since 2012, particularly in NA, which can be attributed to advancements in MM regimens. However, higher mortality rates were observed among patients from AF and AS followed by EU compared to NA and OC. The results highlight the existence of significant disparities in MM outcomes and AMDR toxicities on a global scale. We also found evidence of an increase in secondary neoplasm in regions including AS (M&F) and AF (M), and Oceania (M&F). Our results also showed that the availability of specific AMDRs used in each region played a significant role in the differences in toxicities as shown in Table 1. For instance, R, P, and Rd were among the top AMDRs in NA, and R, Rd, and NRd are the top AMDRs in EU, while V, R, and P were prescribed more frequently in OC. **Conclusions:** The variations observed in mortality rates among different regions underscore the need for targeted interventions to address these disparities. By understanding the regional differences in drug toxicity trends, healthcare professionals can develop personalized treatment strategies to optimize patient outcomes. Further research is warranted to delve deeper into the underlying factors contributing to these disparities, including genetic, socioeconomic, and healthcare system-related factors.

[1]Augusta University

Introduction: Bortezomib (B), used to treat Multiple Myeloma (MM) causes peripheral neuropathy (PN) in an estimated 75% of patients. There are reports of dizziness, muscle weakness and other neurologic problems caused by B. Among patients that received B based induction, in addition to PN, in a small subset we observed profound weight loss, dizziness and orthostatic hypotension (OH). These symptoms frequently impair patients' performance status requiring interruption of therapy. There are few publications on autonomic neuropathy (AN) caused by B but we believe it is under recognized and under diagnosed. We report a series of patients that presented with significant weight loss and OH suggestive of AN, to bring awareness to this problem. **Methods:** From July 2017 to July 2022, patients with MM requiring transplant; complaining of weight loss and dizziness were identified. Medical records were reviewed and a pattern of symptoms and clinical course were identified. Statistics are descriptive and this retrospective study was approved by our Institutional review board. **Results:** Fourteen patients were noted to have symptoms suggestive of AN. 12 received VRD and 2 received (Daratumumab) D-VRD induction. B was given subcutaneously and twice weekly. The median age was 61 years (range 51-76). Nine were African American and 5 White; 5 female, 4 had diabetes but no prior neuropathy. The interval between initiation of therapy and AN symptoms was a median of 124 days (range 50-219) and the median B dose was 20.8 mg/M2 (range 11.7-40.33 mg/M2). All 14 patients had weight loss. The median weight loss and percentage weight loss (compared to baseline weight) were 19.5 Kgs (range 7-39.14 Kgs) and 21% (range 7-41) respectively. Further treatment was held due to decline in performance status in all patients. Eight patients received appetite stimulants; 2 megestrol and 6 dronabinol.

Introduction: Bortezomib (B), used to treat Multiple Myeloma (MM) causes peripheral neuropathy (PN) in an estimated 75% of patients. There are reports of dizziness, muscle weakness and other neurologic problems caused by B. Among patients that received B based induction, in addition to PN, in a small subset we observed profound weight loss, dizziness and orthostatic hypotension (OH). These symptoms frequently impair patients' performance status requiring interruption of therapy. There are few publications on autonomic neuropathy (AN) caused by B but we believe it is under recognized and under diagnosed. We report a series of patients that presented with significant weight loss and OH suggestive of AN, to bring awareness to this problem. **Methods:** From July 2017 to July 2022, patients with MM requiring transplant; complaining of weight loss and dizziness were identified. Medical records were reviewed and a pattern of symptoms and clinical course were identified. Statistics are descriptive and this retrospective study was approved by our Institutional review board. **Results:** Fourteen patients were noted to have symptoms suggestive of AN. 12 received VRD and 2 received (Daratumumab) D-VRD induction. B was given subcutaneously and twice weekly. The median age was 61 years (range 51-76). Nine were African American and 5 White; 5 female, 4 had diabetes but no prior neuropathy. The interval between initiation of therapy and AN symptoms was a median of 124 days (range 50-219) and the median B dose was 20.8 mg/M2 (range 11.7-40.33 mg/M2). All 14 patients had weight loss. The median weight loss and percentage weight loss (compared to baseline weight) were 19.5 Kgs (range 7-39.14 Kgs) and 21% (range 7-41) respectively. Further treatment was held due to decline in performance status in all patients. Eight patients received appetite stimulants; 2 megestrol and 6 dronabinol.

OH was seen in all patients; 3 received fludrocortisone and one received midodrine. 12 patients also had PN requiring neuropathic pain medications and narcotic analgesics. Transplant was delayed by 6 months (range 2-11) to enable recovery and the end-point was weight gain, and resolution of OH. 12 patients received transplant; Post-transplant 1 patient had persistent diarrhea and 1 had persistent dizziness. One patient developed severe mucositis, dysphagia, poor appetite and required hyper alimentation, nasogastric feeding and a feeding gastrostomy tube. With a follow up of 30.2 (range 8.47-53.6) months, the median survival is 30.82 months. **Conclusions:** Severe AN characterized by weight loss, dizziness, OH in association with painful neuropathy is an under recognized complication of B. Transplantation without resolution of symptoms could possibly worsen the morbidity and delay post-transplant recovery. To the best of our knowledge, we are the first group to report a series of patients with this symptom complex and strongly feel it should be studied further in a larger cohort of patients.

P-467

Dietary risk factors for monoclonal gammopathy of undetermined significance in a racially diverse national health and nutrition examination survey (NHANES) case-control study

Janine Joseph[1], Li Tang[1], Jens Hillengass[1], Ola Landgren[2], Saad Usmani[3], Alexander Lesokhin[3], Kirsten Moysich[1], Urvi Shah[4]

[1]Roswell Park Comprehensive Cancer Center; [2]Myeloma Service, Sylvester Comprehensive Cancer Center, University of Miami; [3]Memorial Sloan Kettering Cancer Center, New York City NY, USA; [4]Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: Monoclonal gammopathy of undetermined significance (MGUS) has a prevalence of 3% over age 50 with a 1% annual risk of progression to multiple myeloma. Although one cohort study in Caucasians from Iceland reported that diets low in whole wheat bread and fruits were associated with MGUS (Thordardottir et al. 2018), research on diet and MGUS in a more diverse population is scarce. Given that diet can vary greatly between ethnic/racial groups, we conducted a population-based study of diet and MGUS in a racially diverse population. **Methods:** Using the National Health and Nutrition Examination Survey (NHANES), we conducted a case-control study in 373 individuals with MGUS and 1,406 controls frequency matched on age, body mass index, NHANES cycle, sex, and race. The study sample was diverse, with 27.2% Non-Hispanic Black and 16.0% Mexican American. Diet was characterized by one 24-hour dietary recall, with gram intake of individual foods and beverages aggregated into groups. MGUS status was determined by blood screening. Individuals with MGUS were risk stratified based on Mayo Clinic criteria into low (n=158) and intermediate/high risk (n=180). Unconditional multivariable logistic regressions were used to model associations between intake of several food groups and MGUS and risk stratified MGUS, with odds ratios (OR) and 95% confidence intervals (CI) reported for the highest relative to the lowest quantile of intake. **Results:** Daily intake of several food and beverage groups were significantly associated with MGUS, low-risk MGUS (LRM) or intermediate/high-risk MGUS (IHRM). Inverse associations were observed for fruits and vegetables: OR=0.69 (95% CI 0.52-0.93) (MGUS); fruits: OR=0.62 (95% CI 0.38-0.99) (LRM); vegetables: OR=0.75 (95% CI 0.56-0.99) (MGUS); tomatoes: OR=0.72 (95% CI 0.51-1.00) (MGUS); cruciferous vegetables: OR=0.44 (95% CI 0.26-0.74) (MGUS); OR=0.22 (95% CI 0.09-0.57) (IHRM) and whole-grain bread, oats, rice: OR=0.52 (95% CI 0.28-0.95) (LRM). Direct associations were observed for sugar-sweetened beverages: OR=1.34 (95% CI 1.00-1.78) (MGUS); OR=1.68 (95% CI 1.13-2.49) (LRM); sugar-sweetened soft drinks: OR=1.41 (95% CI 1.01-1.96) (MGUS); artificially sweetened soft drinks: OR=1.55 (95% CI 1.04-2.33) (MGUS); OR=2.13 (95% CI 1.28-3.56) (LRM); and cola, combined sugar- and artificially sweetened: OR=1.59 (95% CI 1.14-2.22) (MGUS); OR=1.77 (95% CI 1.13-2.78) (LRM). There were more significant findings for LRM than IHRM, suggesting potential contributing etiologic differences. **Conclusions:** Our study shows that low intake of whole grains, fruits, and vegetables and high intake of sweetened beverages are associated with MGUS. The identification of dietary risk factors for MGUS in a diverse population is of direct public health relevance. These findings also provide rationale for exploration of mechanistic links between diet and plasma cell disorders, such as the ongoing studies NCT04920084, NCT05640843, and NCT05312255.

Introduction: The introduction of novel agents for multiple myeloma (MM) has significantly improved survival rates. However, with improved overall survival, the development of subsequent second malignancies has become increasingly significant. Despite this, data describing the risk of secondary primary malignancies following MM diagnosis are scarce. This study aimed to compare the risk of secondary malignancy in MM patients to the general population at a nationwide population-based level. **Methods:** We utilized the Korea National Health Insurance Service (KNHIS) database. 37,883 patients diagnosed with MM between January 2009 to December 2020, were selected. Landmark analyses at 1, 3, and 5-year were performed to minimize immortality bias and observe long-term trends. After refining the dataset by age (>19 years), diagnosis repetition, and excluding malignancies within the landmark period, 7,348 MM patients were included in the case cohort. Additionally,

OH was seen in all patients; 3 received fludrocortisone and one received midodrine. 12 patients also had PN requiring neuropathic pain medications and narcotic analgesics. Transplant was delayed by 6 months (range 2-11) to enable recovery and the end-point was weight gain, and resolution of OH. 12 patients received transplant; Post-transplant 1 patient had persistent diarrhea and 1 had persistent dizziness. One patient developed severe mucositis, dysphagia, poor appetite and required hyper alimentation, nasogastric feeding and a feeding gastrostomy tube. With a follow up of 30.2 (range 8.47-53.6) months, the median survival is 30.82 months. **Conclusions:** Severe AN characterized by weight loss, dizziness, OH in association with painful neuropathy is an under recognized complication of B. Transplantation without resolution of symptoms could possibly worsen the morbidity and delay post-transplant recovery. To the best of our knowledge, we are the first group to report a series of patients with this symptom complex and strongly feel it should be studied further in a larger cohort of patients.

Dietary risk factors for monoclonal gammopathy of undetermined significance in a racially diverse national health and nutrition examination survey (NHANES) case-control study

Janine Joseph[1], Li Tang[1], Jens Hillengass[1], Ola Landgren[2], Saad Usmani[3], Alexander Lesokhin[3], Kirsten Moysich[1], Urvi Shah[4]

[1]Roswell Park Comprehensive Cancer Center; [2]Myeloma Service, Sylvester Comprehensive Cancer Center, University of Miami; [3]Memorial Sloan Kettering Cancer Center, New York City NY, USA; [4]Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York City NY, USA

Introduction: Monoclonal gammopathy of undetermined significance (MGUS) has a prevalence of 3% over age 50 with a 1% annual risk of progression to multiple myeloma. Although one cohort study in Caucasians from Iceland reported that diets low in whole wheat bread and fruits were associated with MGUS (Thordardottir et al. 2018), research on diet and MGUS in a more diverse population is scarce. Given that diet can vary greatly between ethnic/racial groups, we conducted a population-based study of diet and MGUS in a racially diverse population. **Methods:** Using the National Health and Nutrition Examination Survey (NHANES), we conducted a case-control study in 373 individuals with MGUS and 1,406 controls frequency matched on age, body mass index, NHANES cycle, sex, and race. The study sample was diverse, with 27.2% Non-Hispanic Black and 16.0% Mexican American. Diet was characterized by one 24-hour dietary recall, with gram intake of individual foods and beverages aggregated into groups. MGUS status was determined by blood screening. Individuals with MGUS were risk stratified based on Mayo Clinic criteria into low (n=158) and intermediate/high risk (n=180). Unconditional multivariable logistic regressions were used to model associations between intake of several food groups and MGUS and risk stratified MGUS, with odds ratios (OR) and 95% confidence intervals (CI) reported for the highest relative to the lowest quantile of intake. **Results:** Daily intake of several food and beverage groups were significantly associated with MGUS, low-risk MGUS (LRM) or intermediate/high-risk MGUS (IHRM). Inverse associations were observed for fruits and vegetables: OR=0.69 (95% CI 0.52-0.93) (MGUS); fruits: OR=0.62 (95% CI 0.38-0.99) (LRM); vegetables: OR=0.75 (95% CI 0.56-0.99) (MGUS); tomatoes: OR=0.72 (95% CI 0.51-1.00) (MGUS); cruciferous vegetables: OR=0.44 (95% CI 0.26-0.74) (MGUS); OR=0.22 (95% CI 0.09-0.57) (IHRM) and whole-grain bread, oats, rice: OR=0.52 (95% CI 0.28-0.95) (LRM). Direct associations were observed for sugar-sweetened beverages: OR=1.34 (95% CI 1.00-1.78) (MGUS); OR=1.68 (95% CI 1.13-2.49) (LRM); sugar-sweetened soft drinks: OR=1.41 (95% CI 1.01-1.96) (MGUS); artificially sweetened soft drinks: OR=1.55 (95% CI 1.04-2.33) (MGUS); OR=2.13 (95% CI 1.28-3.56) (LRM); and cola, combined sugar- and artificially sweetened: OR=1.59 (95% CI 1.14-2.22) (MGUS); OR=1.77 (95% CI 1.13-2.78) (LRM). There were more significant findings for LRM than IHRM, suggesting potential contributing etiologic differences. **Conclusions:** Our study shows that low intake of whole grains, fruits, and vegetables and high intake of sweetened beverages are associated with MGUS. The identification of dietary risk factors for MGUS in a diverse population is of direct public health relevance. These findings also provide rationale for exploration of mechanistic links between diet and plasma cell disorders, such as the ongoing studies NCT04920084, NCT05640843, and NCT05312255.

Risk of secondary primary malignancies after multiple myeloma in the novel therapy era: a nationwide case-control cohort study

Heejoo Ko[1], Suein Choi[2], Seunghoon Han[2], Chang-Ki Min[3], Ja Min Byun[4], Sung-Soo Park[1]

[1]Department of Hematology, Seoul St. Mary's Hematology Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [2]Department of Pharmacology, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [3]Seoul St. Mary's Hospital, Seoul, South Korea; [4]Department of Internal Medicine, Seoul National University College of Medicine, Seoul National University Hospital, Seoul, Korea

Introduction: The introduction of novel agents for multiple myeloma (MM) has significantly improved survival rates. However, with improved overall survival, the development of subsequent second malignancies has become increasingly significant. Despite this, data describing the risk of secondary primary malignancies following MM diagnosis are scarce. This study aimed to compare the risk of secondary malignancy in MM patients to the general population at a nationwide population-based level. **Methods:** We utilized the Korea National Health Insurance Service (KNHIS) database. 37,883 patients diagnosed with MM between January 2009 to December 2020, were selected. Landmark analyses at 1, 3, and 5-year were performed to minimize immortality bias and observe long-term trends. After refining the dataset by age (>19 years), diagnosis repetition, and excluding malignancies within the landmark period, 7,348 MM patients were included in the case cohort. Additionally,

29,351 individuals without MM were matched as controls using 1:4 propensity score matching based on age, sex, and comorbidities. Cumulative incidence of secondary malignancy was compared using the Gray test, treating death as a competing risk. Incidences of secondary malignancy and subtypes were compared, and hazard ratios (HR) were computed using the Fine-Gray subdistribution hazard model. Subgroup analysis based on transplant eligibility was conducted to explore the impact of high dose chemotherapy for autologous stem cell transplantation on the secondary malignancy occurrence. **Results:** Median follow-up was 45.6 months for cases and 51.3 months for controls. The 10-year cumulative incidence rate of any secondary malignancy was significantly higher in cases than controls (10.52% vs. 8.68%, p< 0.001, HR 1.58, 95% confidence interval [CI] 1.38-1.80). The risk of hematologic malignancy was significantly higher in cases than controls (HR 8.03, 95% CI 5.40-11.92; 10-year incidence 2.34% vs. 0.36%, p< 0.001). Notably, the incidence of therapy-related myeloid neoplasms (t-MN) was significantly higher in cases (HR 12.06, 95% CI 6.84-21). There were no significant differences in the 10-year cumulative incidence of non-hematologic malignancy (6.17% vs. 8.29%, p=0.122, HR 0.9) or its subtypes. In the subgroup analysis, any secondary malignancy had significantly increased in the transplant-eligible MM patients compared to transplant-ineligible patients (p< 0.001). **Conclusions:** The incidence of secondary solid malignancies did not differ markedly between MM cases and controls. However, the risk of hematologic malignancy and t-MN in MM patients was significantly higher compared to the general population. Transplant-eligible MM patients had a higher risk of developing any malignancies, suggesting that stem cell transplantation might be an important factor associated with the development of secondary malignancies in patients with MM.

Observational study of COVID-19 prophylactic antibody (tixagevimab/cilgavimab) administration for multiple myeloma patients

Yoojin Lee[1,2], Jae-Cheol Jo[1]

[1]Ulsan University Hospital; [2]University of Ulsan College of Medicine

Introduction: The risk of COVID-19-associated morbidity and mortality among Multiple myeloma (MM) patients remains high during the post-pandemic COVID-19 period. In particular, autologous stem cell transplantation (ASCT) recipients or heavily treated patients may have a diminished response to COVID-19 vaccines. Therefore, we evaluated the efficacy and toxicity of neutralizing antibodies composed of tixagevimab and cilgavimab in the real world. **Methods:** This cross-sectional observational study included 44 patients who received neutralizing antibodies to prevent COVID-19 at our institution between August 16 and 18, 2022 (dominant Omicron variant BA.4, BA.5 in Korea). The patient received tixagevimab/cilgavimab (two consecutive intramuscular injections of 300 mg of tixagevimab and 300 mg of cilgavimab). To detect the serologic response to tixagevimab/cilgavimab and environmental exposure, antibodies against the SARS CoV-2 spike receptor-binding domain (Anti-S Ab) and viral nucleocapsid (Anti-N Ab) were measured. Anti-S ab and anti-N ab tests were performed at 4 time points (0.1.3.6 months). **Results:** A total of 44 MM patients underwent ASCT within two months or received chemo-immunotherapy (median second-line therapy). The median age was 68.5 years (48~ 85 years), and the male was 53.4%. Eight patients (18.2%) had previously confirmed COVID-19 infection. Twenty eight patients (63.6%) had previously received COVID-19 vaccination. In the study, the median anti-S Ab level increased from baseline (997.05 AU/mL) to 1 month (20967.25 AU/mL), then decreased at 3 months (13145.0 AU/mL), and 6 months (7123.0 AU/mL). Fourteen patients (31.8%) had positive anti-N Ab at baseline. There was no significant safety concern with tixagevimab/cilgavimab. Seven patients (15.9%) were infected with COVID-19 after exposure of tixagevimab/cilgavimab. The risk factors for COVID-19 were number of vaccine (1, p=0.010), lower anti-S Ab at 6 month (lower than median, p=0.095), heavily treated multiple myeloma (>3). There was no COVID-19 related mortality. **Conclusions:** Patients with MM are at high risk for severe COVID-19 infection because of age, comorbidity, humoral and cellular immune-compromises. The results of this study support the use of tixagevimab/cilgavimab for the prevention of symptomatic and severe COVID-19. COVID-19 prevention includes a layered strategy including vaccination, masking, and neutralizing antibodies that target the variant appropriately.

Single center experience of denosumab for hypercalcemia in multiple myeloma

Matthew Lei[1], Erica Tavares[1], Uvette Lou[1], E. Bridget Kim[1], Jack Malespini[1], Noopur Raje[1], Andrew Yee[1]

[1]Massachusetts General Hospital, Boston, MA, USA

Introduction: Hypercalcemia (HC) is a frequent complication of multiple myeloma (MM) occurring in 20-30% of patients. This is often associated with renal dysfunction and both features are important myeloma defining events resulting in significant morbidity and mortality. Denosumab, a fully human monoclonal antibody that inhibits RANKL, has been evaluated in the prevention of skeletal related events in patients with newly diagnosed MM, as well as the treatment of bisphosphonate-refractory HC of malignancy (HCM). Cases of denosumab for HCM in MM patients with renal dysfunction have been described. Although denosumab and IV bisphosphonates (IVB) represent treatment options for HC in MM, there is limited data on the use of denosumab for HC in patients with MM. We describe a cohort of patients with MM with HC who received denosumab. **Methods:** We retrospectively identified patients age ≥18 with a diagnosis of MM with HC (corrected serum calcium level [CSC] >10.5 mg/dL). Patients were included if they received denosumab between April 2016 and April 2023. The primary endpoint was complete response (CR), defined as normalization of CSC to less than 10.5 mg/dL. Secondary endpoints included HC relapse (CSC >10.5 mg/dL) and safety. Hypocalcemia was graded per CTCAE v5. Acute kidney injury (AKI) was defined using KGIDO criteria. Patients were followed-up for 56 days.

29,351 individuals without MM were matched as controls using 1:4 propensity score matching based on age, sex, and comorbidities. Cumulative incidence of secondary malignancy was compared using the Gray test, treating death as a competing risk. Incidences of secondary malignancy and subtypes were compared, and hazard ratios (HR) were computed using the Fine-Gray subdistribution hazard model. Subgroup analysis based on transplant eligibility was conducted to explore the impact of high dose chemotherapy for autologous stem cell transplantation on the secondary malignancy occurrence. **Results:** Median follow-up was 45.6 months for cases and 51.3 months for controls. The 10-year cumulative incidence rate of any secondary malignancy was significantly higher in cases than controls (10.52% vs. 8.68%, p< 0.001, HR 1.58, 95% confidence interval [CI] 1.38-1.80). The risk of hematologic malignancy was significantly higher in cases than controls (HR 8.03, 95% CI 5.40-11.92; 10-year incidence 2.34% vs. 0.36%, p< 0.001). Notably, the incidence of therapy-related myeloid neoplasms (t-MN) was significantly higher in cases (HR 12.06, 95% CI 6.84-21). Anti-S ab and anti-N ab tests were performed at 4 time points (0.1.3.6 months). **Results:** A total of 44 MM patients underwent ASCT within two months or received chemo-immunotherapy (median second-line therapy). The median age was 68.5 years (48~ 85 years), and the male was 53.4%. Eight patients (18.2%) had previously confirmed COVID-19 infection. Twenty eight patients (63.6%) had previously received COVID-19 vaccination. In the study, the median anti-S Ab level increased from baseline (997.05 AU/mL) to 1 month (20967.25 AU/mL), then decreased at 3 months (13145.0 AU/mL), and 6 months (7123.0 AU/mL). Fourteen patients (31.8%) had positive anti-N Ab at baseline. There was no significant safety concern with tixagevimab/cilgavimab. Seven patients (15.9%) were infected with COVID-19 after exposure of tixagevimab/cilgavimab. The risk factors for COVID-19 were number of vaccine (1, p=0.010), lower anti-S Ab at 6 month (lower than median, p=0.095), heavily treated multiple myeloma (>3). There was no COVID-19 related mortality. **Conclusions:** Patients with MM are at high risk for severe COVID-19 infection because of age, comorbidity, humoral and cellular immune-compromises. The results of this study support the use of tixagevimab/cilgavimab for the prevention of symptomatic and severe COVID-19. COVID-19 prevention includes a layered strategy including vaccination, masking, and neutralizing antibodies that target the variant appropriately.

Single center experience of denosumab for hypercalcemia in multiple myeloma

Matthew Lei[1], Erica Tavares[1], Uvette Lou[1], E. Bridget Kim[1], Jack Malespini[1], Noopur Raje[1], Andrew Yee[1]

[1]Massachusetts General Hospital, Boston, MA, USA

Introduction: Hypercalcemia (HC) is a frequent complication of multiple myeloma (MM) occurring in 20-30% of patients. This is often associated with renal dysfunction and both features are important myeloma defining events resulting in significant morbidity and mortality. Denosumab, a fully human monoclonal antibody that inhibits RANKL, has been evaluated in the prevention of skeletal related events in patients with newly diagnosed MM, as well as the treatment of bisphosphonate-refractory HC of malignancy (HCM). Cases of denosumab for HCM in MM patients with renal dysfunction have been described. Although denosumab and IV bisphosphonates (IVB) represent treatment options for HC in MM, there is limited data on the use of denosumab for HC in patients with MM. We describe a cohort of patients with MM with HC who received denosumab. **Methods:** We retrospectively identified patients age ≥18 with a diagnosis of MM with HC (corrected serum calcium level [CSC] >10.5 mg/dL). Patients were included if they received denosumab between April 2016 and April 2023. The primary endpoint was complete response (CR), defined as normalization of CSC to less than 10.5 mg/dL. Secondary endpoints included HC relapse (CSC >10.5 mg/dL) and safety. Hypocalcemia was graded per CTCAE v5. Acute kidney injury (AKI) was defined using KGIDO criteria. Patients were followed-up for 56 days.

Bivariate analyses were performed. The Kaplan Meier method was used to estimate time to CR. **Results:** A total of 27 patients were included. 37% (n=10) of patients had newly diagnosed MM. 19% (n=5) of patients received a dose of 60 mg, the majority of whom had significant renal dysfunction; all other patients received a dose of 120 mg. Most patients received HC treatment as an inpatient (67% inpatient vs. 33% outpatient). A minority of patients had received IVBs in the past 90 days (15%; n=4). The median CSC was 12.2 mg/dL (interquartile range [IQR], 11.5-14.0). Baseline median serum creatinine (SCr) and creatinine clearance (CrCl) was 2.2 mg/dL (IQR, 1.2-3.0) and 30.7 mL/min (IQR, 20.8-42.2), respectively. Incidence of AKI at baseline was 63% (n=17). The CR rate by day 10 was 81%. The median time to CR was 3 days (95% CI, 2.7-3.2). Three patients did not achieve CR. HC relapse occurred in 4 (15%) patients. All grade hypocalcemia was 56% (n=15) while grade ≥2 hypocalcemia was 37%; one patient experienced grade 3 hypocalcemia. No patients in the denosumab group received an additional dose of denosumab within 14 days of initial dose. **Conclusions:** We describe our experience with denosumab for the management of HC in patients with MM. The median time to CR was 3 days in our MM only population that was not bisphosphonate refractory. A high incidence of grade 2 hypocalcemia was noted. Conclusions on renal safety are limited by the small sample size. Denosumab represents an acceptable alternative to intravenous bisphosphonates for the management of HC in MM patients with further investigation necessary in those with renal dysfunction.

The MMRF cure cloud research study: a real-world longitudinal investigation of patient treatments and outcomes, including patient reported outcome (PRO) surveys

Eva Lepisto[1], Mark Fiala[2], April Cook[1], Jessica Schulman[1], Anne Quinn Young[1], Erin Mensching[1], Jennifer Rogers[1], Ibrahim Akorede[1], Elizabeth Kane[1], Mary DeRome[1], George Mulligan[1], Hearn Jay Cho[1]

[1]MMRF; [2]Washington University School of Medicine in St. Louis

Introduction: Despite lack of clear curative regimens for multiple myeloma (MM) patients, survival has increased over the past 2 decades. Patients are managed on therapy for years, often progressing through complex treatment regimens. Unfortunately, some patients (e.g. Black Americans, those with high-risk disease) have consistently worse outcomes, and it remains unclear how to optimize therapy for every patient. The MMRF is enrolling a longitudinal research study called CureCloud to engage a US cohort of MM patients along their treatment journey in efforts to understand their treatments, outcomes, personal experiences, and molecular features of the disease. There are no specific therapy or demographic requirements for entry. Patients enroll with their clinical care team or via a direct-to-patient portal, and blood is collected in participants' homes. The study integrates molecular and real-world evidence data, including electronic health records (EHR) and PROs collected at six-month intervals, and is expected to enroll and follow 5000 patients for at least five years. Here we report the first learnings on RWE towards better understanding the impact of therapy on MM patients' short- and long-term quality of life. **Methods:** This was an analysis of the baseline PRO data. The FACIT-COmprehensive Score for financial Toxicity (COST) and the Cancer Therapy Satisfaction Questionnaire (CTSQ) were administered to consented patients with at least 6 months follow-up in 2022 using an emailed web-based link sent to patients between October and December 2022. Patients not completing surveys within the first week received a second email link to the surveys. For completed surveys, a composite score for the COST data was calculated with possible scores ranging from 0-44; higher scores indicate better financial well-being. The CTSQ subscales were calculated with scores ranging from 0-100; higher scores indicate higher satisfaction. **Results:** 976 (96%) of the 1020 consented patients received the PROs. 192 (19%) patients completed the CTSQ and 190 (19%) the COST. Analyses were limited to 175 with active MM (91%) at time of completion. The average score for the CTSQ's expectation of therapy (ET) was 56.5 [SD 18.7], satisfaction with therapy (SWT) was 67.9 [SD 10.8], and feelings about side effects (FSE) 72.5 [SD 16.6]. In bivariate analysis newly diagnosed patients showed increased expectations of therapy. The average COST score was 27.9 [SD 9.3], and no significant differences were observed across demographic characteristics. For both PROs, the relationship with patients' race couldn't be studied due to low representation. **Conclusions:** This longitudinal study continues to enroll active MM patients (newly diagnosed and relapsed), both at clinical sites and through a unique direct to patient format https://mmrfcurecloud.org/ with an emphasis on ensuring inclusivity and racial diversity. The current data reveal initial patient experiences over their MM journey.

Evaluation of the usefulness of the QuantiFERON-TB gold in-tube test for the detection of latent mycobacterium tuberculosis infections in patients underwent autologous stem cell transplantation

Sung-Nam Lim[1,2], Beyong-Sok Sohn[1,3]

[1]Inje University College of Medicine; [2]Haeundae Paik Hospital; [3]Sanggye Paik Hospital

Introduction: Tuberculosis (TB) is still a major global public health problem. The likelihood of developing active disease is much higher in frail patients, such as those with hematopoietic stem cell transplantation (HSCT). Patients undergoing HSCT have severe and prolonged immunodeficiency due to underlying hematologic malignancies, chemo- and immunosuppressive therapy, and are generally considered to be at higher risk for active TB or reactivation of latent TB infections. The aim of this study was to evaluate the occurrence of active TB in patients who received a QuantiFERON test for the detection of latent TB infection. **Methods:** This is a retrospective observational cohort study, including all adult patients (>18 years old) with plasma cell neoplasms who received autologous stem cell transplantation (ASCT). In total, 80 patients who performed an interferon-gamma release assay and underwent

Bivariate analyses were performed. The Kaplan Meier method was used to estimate time to CR. **Results:** A total of 27 patients were included. 37% (n=10) of patients had newly diagnosed MM. 19% (n=5) of patients received a dose of 60 mg, the majority of whom had significant renal dysfunction; all other patients received a dose of 120 mg. Most patients received HC treatment as an inpatient (67% inpatient vs. 33% outpatient). A minority of patients had received IVBs in the past 90 days (15%; n=4). The median CSC was 12.2 mg/dL (interquartile range [IQR], 11.5-14.0). Baseline median serum creatinine (SCr) and creatinine clearance (CrCl) was 2.2 mg/dL (IQR, 1.2-3.0) and 30.7 mL/min (IQR, 20.8-42.2), respectively. Incidence of AKI at baseline was 63% (n=17). The CR rate by day 10 was 81%. The median time to CR was 3 days (95% CI, 2.7-3.2). Three patients did not achieve CR. HC relapse occurred in 4 (15%) patients. All grade hypocalcemia was 56% (n=15) while grade ≥2 hypocalcemia was 37%; one patient experienced grade 3 hypocalcemia. No patients in the denosumab group received an additional dose of denosumab within 14 days of initial dose. **Conclusions:** We describe our experience with denosumab for the management of HC in patients with MM. The median time to CR was 3 days in our MM only population that was not bisphosphonate refractory. A high incidence of grade 2 hypocalcemia was noted. Evaluation of the usefulness of the QuantiFERON-TB gold in-tube test for the detection of latent mycobacterium tuberculosis infections in patients underwent autologous stem cell transplantation

Sung-Nam Lim[1,2], Beyong-Sok Sohn[1,3]

[1]Inje University College of Medicine; [2]Haeundae Paik Hospital; [3]Sanggye Paik Hospital

Introduction: Tuberculosis (TB) is still a major global public health problem. The likelihood of developing active disease is much higher in frail patients, such as those with hematopoietic stem cell transplantation (HSCT). Patients undergoing HSCT have severe and prolonged immunodeficiency due to underlying hematologic malignancies, chemo- and immunosuppressive therapy, and are generally considered to be at higher risk for active TB or reactivation of latent TB infections. The aim of this study was to evaluate the occurrence of active TB in patients who received a QuantiFERON test for the detection of latent TB infection. **Methods:** This is a retrospective observational cohort study, including all adult patients (>18 years old) with plasma cell neoplasms who received autologous stem cell transplantation (ASCT). In total, 80 patients who performed an interferon-gamma release assay and underwent

autologous stem cell transplantation between December 2010 and December 2022 were recruited to determine the usefulness of latent TB infection screening tests. **Results:** Most of the enrolled patients were male (58.7%) with a median age of 54 years old (range, 40 ~ 69 years old). Remission induction therapy was as follows; 40 (58.8%) of bortezomib-based regimens, such as VD or VTD, 12 (17.6%) of lenalidomide-based regimens, such as RVD, and 16 (23.5%) of thalidomide-based regimens, such as TD or TCD. Fifty-three (78%) patients achieved partial response after remission induction and the maximal response before ASCT was as follows; 24 (35.3%) patients of CR, 28 (41.2%) of VGPR, 14 (20.5%) of PR, and 2 (2.9%) of SD, respectively. For conditioning regimen, 54 (79.4%) patients received high-dose melphalan and 14 patients received busulfan-based conditioning. The QuantiFERON screening test was performed within one month before ASCT. Sixty-eight (85%) patients out of a total of 80 patients performed QuantiFERON test screening: 10 (14.7%) were positive, 6 (8.8%) indeterminate, and 52 (76.5%) were negative. There was no difference in test-positive rates between men and women. However, the positive rate was statistically significantly higher in elderly patients more than 60 years (p=0.014). Only 20% of the patients whose test was QuantiFERON test positive took isoniazid prophylaxis, and none of them progressed to active TB over a median follow-up period of 38 months. Active TB recurrence did not occur even in 80% of QuantiFERON test-positive who did not take isoniazid, also. All patients who took isoniazid prophylaxis discontinued it prematurely because of drug side effects. **Conclusions:** In conclusion, 14.7% of our ASCT population had latent TB infection and only 20% of them received isoniazid prophylaxis. Regardless of the use of isoniazid prophylaxis, there was no case of active TB progression in a cohort of 68 multiple myeloma patients who underwent ASCT from 2010 to 2022.

P-473

Real-world evidence of statins and oral antidiabetics for multiple myeloma

Nieves Lopez-Muñoz[1], Gema Hernández-Ibarburu[2], Jose Maria Sanchez[1], Rafael Alonso[1], Clara Cuellar[1], Maria Calbacho[1], M Teresa Cedena[1], Ana Jimenez-Ubieto[1], Rosa Ayala[1], Laura Meloni[3], David Perez-Rey[2], Joaquín Martínez-López[4]

[1]Hematología Hospital 12 de Octubre, Madrid, Spain; [2]Biomedical Informatics Group, Universidad Politécnica de Madrid; [3]TriNetX, LLC, Cambridge, MA USA

Introduction: Statins are drugs frequently used in patients with hypercholesterolaemia, and metformin is frequently used in patients with diabetes mellitus. The first one act by inhibiting the enzyme 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase, which functions in the same metabolic pathway as bisphosphonates. Some studies have suggested that statins may increase survival in patients with multiple myeloma, in addition to decreasing bone events. On the other hand, studies suggest that metformin stops the cell cycle of multiple myeloma cells, impairing mitochondrial function. The objective of this study is analyzing the impact of statins and oral antidiabetics treatment in a large cohort of patients with multiple myeloma. For the proposed analysis, we used data from TriNetx, a global federated health research platform that includes patients from Europe and US. **Methods:** Patients had symptomatic multiple myeloma (ICD-10-CM code C90.0) diagnosed between 2007 and 2022. First of all, comparator cohorts included 16,852 MM patients from US and EMEA Collaborative Networks, 7529 were treated with statins. After propensity scoring matching by age, sex, and date of diagnosis we selected 5038 patients in each cohorts. In both groups, patients received the statin as a treatment for hypercholesterolemia. In relation to oral antidiabetics treatment, comparator cohorts included 13,972 MM patients from US and EMEA Collaborative Networks, 7094 were treated with oral antidiabetics. After propensity scoring matching by age, sex, and date of diagnosis we selected 6495 patients in each cohorts. Kaplan−Meier analysis was used to estimate survival probabilities, and between-group differences were tested using the log-rank test and hazard ratio. **Results:** Patients treated with statins had a longer overall survival (OS) than those who did not: HR 0.789 (0.740, 0.841; 95%) p< 0.001. (Figure 1). The median OS was 96.11 months vs. 74.25 months, respectively. Also, patients treated with oral antidiabetics had a longer overall survival (OS), the median OS was 110.66 months vs. 86.16 months, respectively (p< 0.001) (Figure 2). **Conclusions:** This large-scale study based on real-world data confirms the statins and oral antidiabetics significantly prolongs survival in MM.

The effect of elranatamab on patient-reported outcomes in patients with relapsed/refractory multiple myeloma naïve and exposed to BCMA-directed therapies: results from the MagnetisMM-3 study

Mohamad Mohty[1], Nizar Bahlis[2], Ajay Nooka[3], Marco DiBonaventura[4], Jinma Ren[4], Umberto Conte[4], Andrea Viqueira[5]

[1]Sorbonne University, Saint-Antoine Hospital, AP-HP INSERM UMRs 938, Paris, France; [2]Arnie Charbonneau Cancer Institute, University of Calgary; [3]Winship Cancer Institute, Emory University School of Medicine; [4]Pfizer Inc; [5]Pfizer SLU, Madrid, Spain

Introduction: Elranatamab is a humanized bispecific antibody that targets both B-cell maturation antigen (BCMA)-expressing multiple myeloma (MM) cells and CD3-expressing T cells. MagnetisMM-3 (NCT04649359) is an open-label, multicenter, non-randomized, phase 2 study to evaluate the safety and efficacy of elranatamab monotherapy in patients (pts) with relapsed/refractory MM (RRMM). Patient-reported outcomes (PROs) from this study are presented. **Methods:** MagnetisMM-3 enrolled two cohorts of pts (Cohort A: BCMA-naïve; Cohort B: BCMA-exposed) who were refractory to at least 1 proteasome inhibitor, 1 immunomodulatory drug, and 1 anti-CD38 antibody. Pts received subcutaneous elranatamab 76 mg QW on a 28-day cycle with a 2-step-up priming dose regimen (12 mg and 32 mg) administered during the first week. PROs included the EORTC QLQ-C30, the EORTC MY20, and the EQ-5D generic quality of life (QoL) questionnaire. PROs were

autologous stem cell transplantation between December 2010 and December 2022 were recruited to determine the usefulness of latent TB infection screening tests. **Results:** Most of the enrolled patients were male (58.7%) with a median age of 54 years old (range, 40 ~ 69 years old). Remission induction therapy was as follows; 40 (58.8%) of bortezomib-based regimens, such as VD or VTD, 12 (17.6%) of lenalidomide-based regimens, such as RVD, and 16 (23.5%) of thalidomide-based regimens, such as TD or TCD. Fifty-three (78%) patients achieved partial response after remission induction and the maximal response before ASCT was as follows; 24 (35.3%) patients of CR, 28 (41.2%) of VGPR, 14 (20.5%) of PR, and 2 (2.9%) of SD, respectively. For conditioning regimen, 54 (79.4%) patients received high-dose melphalan and 14 patients received busulfan-based conditioning. The QuantiFERON screening test was performed within one month before ASCT. For the proposed analysis, we used data from TriNetx, a global federated health research platform that includes patients from Europe and US. **Methods:** Patients had symptomatic multiple myeloma (ICD-10-CM code C90.0) diagnosed between 2007 and 2022. First of all, comparator cohorts included 16,852 MM patients from US and EMEA Collaborative Networks, 7529 were treated with statins. After propensity scoring matching by age, sex, and date of diagnosis we selected 5038 patients in each cohorts. In both groups, patients received the statin as a treatment for hypercholesterolemia. In relation to oral antidiabetics treatment, comparator cohorts included 13,972 MM patients from US and EMEA Collaborative Networks, 7094 were treated with oral antidiabetics. After propensity scoring matching by age, sex, and date of diagnosis we selected 6495 patients in each cohorts. Kaplan−Meier analysis was used to estimate survival probabilities, and between-group differences were tested using the log-rank test and hazard ratio. **Results:** Patients treated with statins had a longer overall survival (OS) than those who did not: HR 0.789 (0.740, 0.841; 95%) p< 0.001. (Figure 1). The median OS was 96.11 months vs. 74.25 months, respectively. Also, patients treated with oral antidiabetics had a longer overall survival (OS), the median OS was 110.66 months vs. 86.16 months, respectively (p< 0.001) (Figure 2). **Conclusions:** This large-scale study based on real-world data confirms the statins and oral antidiabetics significantly prolongs survival in MM.

The effect of elranatamab on patient-reported outcomes in patients with relapsed/refractory multiple myeloma naïve and exposed to BCMA-directed therapies: results from the MagnetisMM-3 study

Mohamad Mohty[1], Nizar Bahlis[2], Ajay Nooka[3], Marco DiBonaventura[4], Jinma Ren[4], Umberto Conte[4], Andrea Viqueira[5]

[1]Sorbonne University, Saint-Antoine Hospital, AP-HP INSERM UMRs 938, Paris, France; [2]Arnie Charbonneau Cancer Institute, University of Calgary; [3]Winship Cancer Institute, Emory University School of Medicine; [4]Pfizer Inc; [5]Pfizer SLU, Madrid, Spain

Introduction: Elranatamab is a humanized bispecific antibody that targets both B-cell maturation antigen (BCMA)-expressing multiple myeloma (MM) cells and CD3-expressing T cells. MagnetisMM-3 (NCT04649359) is an open-label, multicenter, non-randomized, phase 2 study to evaluate the safety and efficacy of elranatamab monotherapy in patients (pts) with relapsed/refractory MM (RRMM). Patient-reported outcomes (PROs) from this study are presented. **Methods:** MagnetisMM-3 enrolled two cohorts of pts (Cohort A: BCMA-naïve; Cohort B: BCMA-exposed) who were refractory to at least 1 proteasome inhibitor, 1 immunomodulatory drug, and 1 anti-CD38 antibody. Pts received subcutaneous elranatamab 76 mg QW on a 28-day cycle with a 2-step-up priming dose regimen (12 mg and 32 mg) administered during the first week. PROs included the EORTC QLQ-C30, the EORTC MY20, and the EQ-5D generic quality of life (QoL) questionnaire. PROs were

autologous stem cell transplantation between December 2010 and December 2022 were recruited to determine the usefulness of latent TB infection screening tests. **Results:** Most of the enrolled patients were male (58.7%) with a median age of 54 years old (range, 40 ~ 69 years old). Remission induction therapy was as follows; 40 (58.8%) of bortezomib-based regimens, such as VD or VTD, 12 (17.6%) of lenalidomide-based regimens, such as RVD, and 16 (23.5%) of thalidomide-based regimens, such as TD or TCD. Fifty-three (78%) patients achieved partial response after remission induction and the maximal response before ASCT was as follows; 24 (35.3%) patients of CR, 28 (41.2%) of VGPR, 14 (20.5%) of PR, and 2 (2.9%) of SD, respectively. For conditioning regimen, 54 (79.4%) patients received high-dose melphalan and 14 patients received busulfan-based conditioning. The QuantiFERON screening test was performed within one month before ASCT. Sixty-eight (85%) patients out of a total of 80 patients performed QuantiFERON test screening: 10 (14.7%) were positive, 6 (8.8%) indeterminate, and 52 (76.5%) were negative. There was no difference in test-positive rates between men and women. However, the positive rate was statistically significantly higher in elderly patients more than 60 years (p=0.014). Only 20% of the patients whose test was QuantiFERON test positive took isoniazid prophylaxis, and none of them progressed to active TB over a median follow-up period of 38 months. Active TB recurrence did not occur even in 80% of QuantiFERON test-positive who did not take isoniazid, also. All patients who took isoniazid prophylaxis discontinued it prematurely because of drug side effects. **Conclusions:** In conclusion, 14.7% of our ASCT population had latent TB infection and only 20% of them received isoniazid prophylaxis. Regardless of the use of isoniazid prophylaxis, there was no case of active TB progression in a cohort of 68 multiple myeloma patients who underwent ASCT from 2010 to 2022.

Introduction: Statins are drugs frequently used in patients with hypercholesterolaemia, and metformin is frequently used in patients with diabetes mellitus. The first one act by inhibiting the enzyme 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase, which functions in the same metabolic pathway as bisphosphonates. Some studies have suggested that statins may increase survival in patients with multiple myeloma, in addition to decreasing bone events. On the other hand, studies suggest that metformin stops the cell cycle of multiple myeloma cells, impairing mitochondrial function. The objective of this study is analyzing the impact of statins and oral antidiabetics treatment in a large cohort of patients with multiple myeloma. For the proposed analysis, we used data from TriNetx, a global federated health research platform that includes patients from Europe and US. **Methods:** Patients had symptomatic multiple myeloma (ICD-10-CM code C90.0) diagnosed between 2007 and 2022. First of all, comparator cohorts included 16,852 MM patients from US and EMEA Collaborative Networks, 7529 were treated with statins. After propensity scoring matching by age, sex, and date of diagnosis we selected 5038 patients in each cohorts. In both groups, patients received the statin as a treatment for hypercholesterolemia. In relation to oral antidiabetics treatment, comparator cohorts included 13,972 MM patients from US and EMEA Collaborative Networks, 7094 were treated with oral antidiabetics. After propensity scoring matching by age, sex, and date of diagnosis we selected 6495 patients in each cohorts. The effect of elranatamab on patient-reported outcomes in patients with relapsed/refractory multiple myeloma naïve and exposed to BCMA-directed therapies: results from the MagnetisMM-3 study

Mohamad Mohty[1], Nizar Bahlis[2], Ajay Nooka[3], Marco DiBonaventura[4], Jinma Ren[4], Umberto Conte[4], Andrea Viqueira[5]

[1]Sorbonne University, Saint-Antoine Hospital, AP-HP INSERM UMRs 938, Paris, France; [2]Arnie Charbonneau Cancer Institute, University of Calgary; [3]Winship Cancer Institute, Emory University School of Medicine; [4]Pfizer Inc; [5]Pfizer SLU, Madrid, Spain

Introduction: Elranatamab is a humanized bispecific antibody that targets both B-cell maturation antigen (BCMA)-expressing multiple myeloma (MM) cells and CD3-expressing T cells. MagnetisMM-3 (NCT04649359) is an open-label, multicenter, non-randomized, phase 2 study to evaluate the safety and efficacy of elranatamab monotherapy in patients (pts) with relapsed/refractory MM (RRMM). Patient-reported outcomes (PROs) from this study are presented. **Methods:** MagnetisMM-3 enrolled two cohorts of pts (Cohort A: BCMA-naïve; Cohort B: BCMA-exposed) who were refractory to at least 1 proteasome inhibitor, 1 immunomodulatory drug, and 1 anti-CD38 antibody. Pts received subcutaneous elranatamab 76 mg QW on a 28-day cycle with a 2-step-up priming dose regimen (12 mg and 32 mg) administered during the first week. PROs included the EORTC QLQ-C30, the EORTC MY20, and the EQ-5D generic quality of life (QoL) questionnaire. PROs were

assessed on day (D) 1 and 15 of the first 3 cycles and D1 of each subsequent cycle (C) through C12, the last cycle included in this analysis. The data cut-off was January 12, 2023 (approximately 12 months after the last pt's initial dose). **Results:** 123 and 64 pts were enrolled and treated with elranatamab in Cohort A and B, respectively. Median age was 68.0 and 67.0 years, 55.3% and 46.9% were male, 58.5% and 68.8% were White. At baseline, 25.2% and 20.3% had high risk cytogenetics, 15.4% and 23.4% had R-ISS III, and 31.7% and 57.8% had extramedullary disease. The median number of prior treatment lines was 5.0 (range: 2-22) and 7.5 (3-19). Among pts in Cohort A, a transient worsening in the global health score (QLQ-C30) and side effects domain (MY20) relative to baseline was observed through C2D15 (least square mean [LSM] change=-5.9 [95%CI: -10.7, -1.1] and 4.3 [1.4, 7.2], respectively); both domains reverted to baseline levels by C3D1 and generally showed (non-significant) improvement from baseline starting at C7D1/C8D1. Significant reductions in pain (QLQ-C30) and disease symptoms (MY20) were observed starting at C4D1 (-6.7 [-13.0, -0.4]) and C5D1 (-6.9 [-10.6, -3.1], respectively) and were maintained. Overall QoL (EQ-5D) significantly improved by C11D1 (0.06 [0.02, 0.09]) and was maintained. Cohort B results were largely similar, though, due to small sample sizes, significant differences were less frequent. Only a modest (non-significant) worsening in the global health score was observed with the nadir at C1D15 (-2.0 [-8.0, 4.0]) followed by a (non-significant) improvement relative to baseline by C2D15 (5.2 [-2.6, 13.0]) which was maintained. A reduction (significant at select time points) of pain and disease symptoms was largely observed starting at C2D1 (-5.1 [-13.0, 2.8] and -9.9 [-17.4, -2.4]) and maintained. **Conclusions:** Despite occasional early transient decreases, the results suggest that subcutaneous 76 mg QW elranatamab can improve the symptom and overall QOL of pts with RRMM, regardless of prior BCMA-targeted treatment.

Are we downplaying toxicity with our choice of words? A systematic review of randomized myeloma trials

Mimi Najjar[1], John McCarron[2], Edward Cliff[3], Katherine Berger[4], David Steensma[5], Samer Al Hadidi[6], Rajshekhar Chakraborty[7], Aaron Goodman[8], Douglas Sborov[9], Ghulam Rehman Mohyuddin[9]

[1]University of Balamand; [2]University of Utah; [3]Program on Regulation, Therapeutics and Law, Brigham and Womens Hospital, Harvard Medical School; [4]Unaffiliated Patient Advocate; [5]LLC, Lincoln, MA; [6]Myeloma Center, University of Arkansas for Medical Sciences; [7]University of Columbia; [8]University of California San Diego; [9]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, USA

Introduction: Advances in multiple myeloma (MM) treatment have led to improved survival, but most patients still require long-term therapy. Treatment can result in burdensome toxicities and profoundly affect patients' quality of life. In seeking to emphasize the efficacy of tested treatments, reports of clinical trials may use subjective, vague, or otherwise minimizing terms to downplay adverse events (AEs). To evaluate how AE patterns are reported, we conducted a systematic review of MM randomized controlled trials (RCTs) from 2015-2023. We sought to estimate the prevalence of the use of minimizing terms in MM RCTs and to identify and explore the characteristics of studies that use these terms. **Methods:** We searched MEDLINE/PubMed, Embase, and the Cochrane Registry of Controlled Trials to measure the prevalence of minimizing terms in MM RCTs. Our inclusion criteria were all published MM RCTs from 2015-2023. The Chi square test was used to calculate differences in proportions. "Minimizing terms" were defined as subjective terms used to describe the safety profile of the intervention. Terms searched included "convenient", "manageable", "acceptable', "expected", "well-tolerated", "tolerable", "favorable" and "safe". **Results:** A total of 65 RCTs were included. Among these trials, 86% employed minimizing terms when describing treatment toxicities. The most frequently used terms were "well-tolerated" or "tolerable" in 45% of studies, "manageable" in 28% and "acceptable" in 25% of studies. The rates of grade 3/4 adverse events in the examined RCTs ranged from 23.1%-94% with a median of 74.7%. Minimizing terms were used in 88% of study reports with more grade 3/4 AEs than the median (i.e., >74.7% high grade AE rates), compared to a similar frequency (85%, X2 (1, N = 65) = .082, p = .774 (>.05)) in studies with fewer grade 3/4 AEs than the median. The rates of grade 5 adverse events ranged from 0%-19% with a median of 3%; minimizing terms were used in 100% of studies with more grade 5 AEs (deaths) than the median (3%), which was similar (82.1%, X2 (1, N = 65) = 3.606, p = .058 (>.05)) in studies with fewer than median grade 5 AEs. This suggests that the use of minimizing terms was not associated with the actual incidence of grade 3/4 toxicities or of treatment-related deaths.Industry-sponsored studies were more likely to use minimizing terms: 37/39 industry-sponsored studies (95%) vs 19/26 non-industry/cooperative group studies (73%) used minimizing terms, X2 (1, N = 65) = 6.2, p = .013. A minority of studies (25 of 65, 39%) reported patient reported outcomes (PROs). Studies that reported PROs used minimizing terms less often (18 out of 25, 72%) compared to those that did not report PROs (38 out of 40, 95%), X2 (1, N = 65) = 6.8, p = .009. **Conclusions:** Trial investigators and sponsors regularly use minimizing terms to describe toxicity in MM trials, especially in industry-sponsored studies, and this descriptive terminology does not reflect the actual rates of AEs or deaths in these studies.

Studies that reported PROs used minimizing terms less often (18 out of 25, 72%) compared to those that did not report PROs (38 out of 40, 95%), X2 (1, N = 65) = 6.8, p = .009. **Conclusions:** Trial investigators and sponsors regularly use minimizing terms to describe toxicity in MM trials, especially in industry-sponsored studies, and this descriptive terminology does not reflect the actual rates of AEs or deaths in these studies.

University of Melbourne, Melbourne, VIC, Australia; [3]Royal Prince Alfred Hospital, The University of Sydney; [4]St Vincents Hospital; [5]Princess Alexandra Hospital; [6]School of Medical Sciences, University of Sydney; [7]Alfred Health-Monash University, Melbourne, VIC, Australia

Introduction: Many patients on the ANZ Myeloma and Related Diseases Registry (MRDR) stop standard-of-care (SoC) therapy prematurely. This impaired duration on therapy (DoT) reduces the potential survival benefit of the therapy. We hypothesise that if clinicians were made aware of emerging symptoms, DoT could be optimised with timely supportive care, which would enhance treatment effectiveness. MY-PROMPT-2 builds on our pilot MY-PROMPT randomized controlled trial (RCT) that confirmed the feasibility and acceptability of real-time patient reported outcome measure (PROM) feedback to clinicians. In patients with relapsed MM (RMM), receiving SoC lenalidomide (R), carfilzomib (K) or daratumumab (D)-based therapies, we aim to determine whether routine real-time PROMs feedback to clinicians at patient visits improves event-free survival (EFS: time from randomization to an event [permanent discontinuation of treatment, progression or death]) compared to patients on SoC alone. **Methods:** This parallel, non-blinded, multicenter Bayesian RCT, uses 1:1 allocation, stratified by 3 SoC regimens (R, K, or D-based) and age with provision to recruit 200 adults. **Intervention:** PROM results summary fed back to clinicians at monthly visits for 12 months. PROMs used: 1. MyPOS: MM-specific, 30 items - symptoms/ mood/ healthcare support. 2. Additional regimen-specific questions (≤5) for common side effects of K, and D-based regimens. **ePROM system:** REDCap-based for easy implementation in routine care. PROMs are emailed to intervention patients 1 week before visits. Completion in clinic is also available. A PROM summary is emailed to the clinician, patient, and site staff. PROMs to compare health-related quality of life (EORTC QLQ-C30) and treatment satisfaction (TSQM-9) between groups are collected 3-monthly in both arms for 12 months. Novel statistical trial design: Once ≥60 events have been observed between the 2 arms, EFS monitoring comparing the intervention versus control arm, starts. Using pre-established criteria, if monitoring shows: 1. the intervention arm is inferior to controls, the trial will be stopped; 2. the intervention arm is superior to controls, the Trial Management Committee can declare: 1. Proof of concept (i.e. publish) - if statistical thresholds are met or 2. Recommend further expansion of trial (subject to funding). An economic evaluation will explore the cost-effectiveness of the new model of care. **Results:** Recruitment has commenced and will be active at up to 15 sites. **Conclusions:** This is the first registry-based multicenter trial in patients with RMM to test the benefit of real-time PROM reporting. The widely used ePROM platform facilitates translation into practice and the pragmatic trial design suits rare diseases allowing a smaller sample size to guide decisions to adopt real-time PROM reporting. Findings could be translatable to other cancers, chronic diseases and disease registries.

Pre-exposure prophylaxis for COVID-19 with tixagevimab/cilgavimab (evusheld) in patients with multiple myeloma in the omicron SARS-COV-2 era

Ioannis Ntanasis-Stathopoulos[1], Maria Gavriatopoulou[1], Evangelos Eleutherakis-Papaiakovou[1], Panagiotis Malandrakis[1], Vassiliki Spiliopoulou[1], Rodanthi-Eleni Syrigou[1], Foteini Theodorakakou[1], Despina Fotiou[1], Magdalini Migkou[1], Maria Roussou[1], Efstathios Kastritis[1], Meletios Dimopoulos[1], Evangelos Terpos[1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece

Introduction: In patients with multiple myeloma (MM), SARS-CoV-2 infection has been associated with severe clinical course and high mortality rates, due to the concomitant disease- and treatment-related immunosuppression. Furthermore, immune response to COVID-19 vaccination is attenuated. Therefore, patients with MM are eligible to receive pre-exposure prophylaxis with tixagevimab/cilgavimab (Evusheld). **Methods:** Consecutive patients with MM were prospectively enrolled in the study. All patients had measurement of neutralizing antibodies (NAbs) against SARS-CoV-2 using an FDA approved methodology (enzyme-linked immunosorbent assay, cPass SARS-CoV-2 NAbs Detection Kit; GenScript, Piscataway, NJ, USA) before the administration of tixagevimab/cilgavimab and at one month thereafter. Evusheld was administered at 150mg as two intramuscular injections. **Results:** Fifty-five patients with MM were included in this analysis and were followed for a median of 5 months (range 3-6 months) after receiving tixagevimab/cilgavimab. The median age was 63 years (range 36-84), whereas 27 (49%) were females. The majority of the patients had performance status (PS) 0 (n=27, 49%), 22 patients (40%) has PS 1 and 6 patients (11%) had PS 2. Thirty patients (55%) were ISS 1, 17 (30%) were ISS 2 and 8 (15%) were ISS 3. Most patients (n=37, 67%) were at their first line of treatment, 16 (19%) were receiving their second line of treatment, one patient was at the third and one at the fifth line of treatment. Thirty-one patients (56%) had previously received autologous stem cell transplant. At the time of tixagevimab/cilgavimab administration, 19 patients (34%) were receiving combinations including anti-BCMA agents, 24 patients (44%) were receiving combination including anti-CD38 drugs and 12 (22%) were on other treatments. Four patients had a prior history of COVID-19. Regarding vaccination status for COVID-19, 42 patients (76%) had received 4 vaccine doses and 13 patients (24%) had received 3 vaccine shots. All patients were vaccinated with mRNA-based vaccines. The median NAb level before the administration of tixagevimab/cilgavimab was 87% (range 0-98%), whereas it increased to 97% (range 0-98%) at one month thereafter. Overall, 5 patients (9%) were diagnosed with COVID-19 at a median of 1 month (range 1-2) after receiving tixagevimab/cilgavimab. All of these patients received nirmatrelvir/ritonavir (Paxlovid) for 5 days as outpatients along with supportive care as per standard clinical practice and recovered completely. There were no COVID-19-related hospitalization or deaths. Tixagevimab/

Introduction: In patients with multiple myeloma (MM), SARS-CoV-2 infection has been associated with severe clinical course and high mortality rates, due to the concomitant disease- and treatment-related immunosuppression. Furthermore, immune response to COVID-19 vaccination is attenuated. Therefore, patients with MM are eligible to receive pre-exposure prophylaxis with tixagevimab/cilgavimab (Evusheld). **Methods:** Consecutive patients with MM were prospectively enrolled in the study. All patients had measurement of neutralizing antibodies (NAbs) against SARS-CoV-2 using an FDA approved methodology (enzyme-linked immunosorbent assay, cPass SARS-CoV-2 NAbs Detection Kit; GenScript, Piscataway, NJ, USA) before the administration of tixagevimab/cilgavimab and at one month thereafter. Evusheld was administered at 150mg as two intramuscular injections. **Results:** Fifty-five patients with MM were included in this analysis and were followed for a median of 5 months (range 3-6 months) after receiving tixagevimab/cilgavimab. The median age was 63 years (range 36-84), whereas 27 (49%) were females. The majority of the patients had performance status (PS) 0 (n=27, 49%), 22 patients (40%) has PS 1 and 6 patients (11%) had PS 2. Thirty patients (55%) were ISS 1, 17 (30%) were ISS 2 and 8 (15%) were ISS 3. Most patients (n=37, 67%) were at their first line of treatment, 16 (19%) were receiving their second line of treatment, one patient was at the third and one at the fifth line of treatment. Thirty-one patients (56%) had previously received autologous stem cell transplant. At the time of tixagevimab/cilgavimab administration, 19 patients (34%) were receiving combinations including anti-BCMA agents, 24 patients (44%) were receiving combination including anti-CD38 drugs and 12 (22%) were on other treatments. Four patients had a prior history of COVID-19. Regarding vaccination status for COVID-19, 42 patients (76%) had received 4 vaccine doses and 13 patients (24%) had received 3 vaccine shots. All patients were vaccinated with mRNA-based vaccines. The median NAb level before the administration of tixagevimab/cilgavimab was 87% (range 0-98%), whereas it increased to 97% (range 0-98%) at one month thereafter. Overall, 5 patients (9%) were diagnosed with COVID-19 at a median of 1 month (range 1-2) after receiving tixagevimab/cilgavimab. All of these patients received nirmatrelvir/ritonavir (Paxlovid) for 5 days as outpatients along with supportive care as per standard clinical practice and recovered completely. There were no COVID-19-related hospitalization or deaths. Tixagevimab/

cilgavimab was well tolerated; no infusion-related reactions or major adverse events were reported. Fifteen patients (27%) experienced pain at the injection site that resolved after a few days. **Conclusions:** Tixagevimab/cilgavimab (Evusheld) seems beneficial in patients with MM who had a low incidence of COVID-19 infections during the Omicron wave. No new safety concerns emerged.

Humanistic, clinical, and economic burden in patients with relapsed or refractory multiple myeloma on second line or higher therapy: a systematic literature review

Kody Pierce[1], Kaustav Chatterjee[1], Yao Wang[2], Amyn Malik[2], Erin Cook[2], Yan Song[2], Allison Quintana[2], Tulika Mohan[2], Cesar Rodriguez[3], Paula Rodríguez-Otero[4]

[1]AbbVie; [2]Analysis Group, Inc; [3]Icahn School of Medicine at Mount Sinai; [4]Clínica Universidad de Navarra, CIMA, CIBERONC, IDISNA, Pamplona, Spain

Introduction: Novel therapies in relapsed/refractory multiple myeloma (RRMM) are demonstrating promising efficacy, however the complexity of their administration in real-world settings could further impact the humanistic aspect of management; thus, making an emphasis on QOL and patient reported outcomes (PRO) key in future clinical trials. The objective of the study was to understand real-world evidence on the humanistic, clinical, and economic burden of RRMM. **Methods:** A systematic literature review (SLR) was conducted to identify real-world studies of patients with RRMM from 2018 to September 1, 2022, with outcomes of interest. Studies were identified via the MEDLINE and EMBASE databases, and selected conference proceedings. All studies were required to have at least 100 patients. Titles/abstracts and full text articles were reviewed by 2 reviewers in parallel. Data were extracted from relevant articles and were descriptively summarized. **Results:** Of the 1,170 studies identified, 51 were included in the review. The majority of the studies (n=38) reported clinical outcomes, 12 reported economic outcomes and 3 reported humanistic outcomes. Overall survival (OS) was included in most studies reporting clinical outcomes (34, 89.5%) with progression free survival (PFS) included in (27,71.1%) studies. The median OS of patients with 4L+ RRMM ranged from 8.2 to 21.1 months while the median PFS ranged from 2.0 to 8.9 months. The mean all-cause cost per patient per month ranged from $2,952-$15,726 for inpatient and $5,025-$15,807 for outpatient. Of studies identified on humanistic burden most focused on burden from the patient perspective including PROs and health related quality of life (HRQoL). However, some studies reported on humanistic burden from a macro or caregiver perspective including absenteeism and caregiver QoL. For patients with 4L+, thinking about illness, worried about health, and worried about dying PRO domains only worsened from baseline (N=87, LS mean change from BL was –7.5, –9.7, and –14.4 respectively). Another study reported on the diminished QoL for caregivers using the CareGiver Oncology QOL questionnaire (74.5 for newly diagnosed multiple myeloma [NDMM], 73.2 for 2-3L, and 71.7 for 4L+; scored 0-100 with 100 representing normal/better QoL). **Conclusions:** The median OS for patients with 4L+ RRMM was less than 2 years, indicating that the 4L+ population continues to have a large unmet need for therapy options. Patient and caregiver burden in MM is significant and there is an urgent need for effective therapies that can reduce patient and caregiver burden and improve efficacy while maintaining quality of life.

P-479

Disparities in clinical trial enrolment and survival outcomes by socio-economic class in multiple myeloma

Amrutha Sridhar[1], Selina Chavda[2], Hannah Hsu[1], Hanna Renshaw[1], Fatjon Dekaj[1], Samir Asher[3], Catriona Mactier[4], Shumi Tattersfield[1], Neil Rabin[3], Kwee Yong[2], Ashutosh Wechalekar[4], Ayesha Shameem Mahmood[5], Lydia Lee[3], Annabel McMillan[3], Xenofon Papanikolaou[3], Jonathan Sive[3], Charalampia Kyriakou[3], Rakesh Popat[1]

[1]NIHR UCLH Clinical Research Facility; [2]Cancer Institute, University College London, London, United Kingdom; [3]University College London Hospitals NHS Foundation Trust; [4]Department of Haematology, University College London Hospital; [5]National Amyloidosis Centre, University College London, London, United Kingdom

Introduction: Disparities in patients enrolled into clinical trials compared to real world populations have been reported with underrepresentation of different racial groups. However socio-economic class may also serve as a cause of inequity, particularly as social deprivation has been associated with overall survival (OS). Adequate sociodemographic representation is required for equitable access and for clinical trials to be informative of the population they serve. The aims of the study were to identify the distribution of patients enrolled into Multiple Myeloma (MM) clinical trials according to social deprivation and understand interactions with race, prognostic markers, and OS. **Methods:** This was a retrospective analysis of MM patients treated in the UK between 2014-2023 from electronic medical records. Social deprivation was assessed using the English Indices of Multiple Deprivation (IMD) ranking, derived from income, employment, health, education, housing barriers, services, crime, and living environment. Comparator data was obtained from the National Cancer Registration and Analysis Service for England (NCRAS, 2006-2015). OS was estimated using Kaplan Meier Curves and correlative analysis by Cox regression models with GraphPad prism V9. **Results:** 580 consecutive patients were grouped by 3 cohorts: standard of care (SOC, n=212), clinical trials (n=355): early phase trials (EPT, Phase I/II, n=103) late phase trials (LPT, Phase II & III, n=252). Median age was 66 years (35-90), M:F ratio was 1.3:1 and had a median of 3 prior lines (0-14). 406 (70%) were White, 80 (13.8%) Black, 40 (6.9%) Asian, 38 (6.6%) Mixed/Other and 16 (2.8%) unknown. There were significantly less patients enrolled into clinical trials (both EPT and LPT) from deprived areas compared to the expected social demographic of MM patients in England (7% (trials) vs 14% (England) for IMD 5, p=< 0.001).

cilgavimab was well tolerated; no infusion-related reactions or major adverse events were reported. Fifteen patients (27%) experienced pain at the injection site that resolved after a few days. **Conclusions:** Tixagevimab/cilgavimab (Evusheld) seems beneficial in patients with MM who had a low incidence of COVID-19 infections during the Omicron wave. No new safety concerns emerged.

Introduction: Disparities in patients enrolled into clinical trials compared to real world populations have been reported with underrepresentation of different racial groups. However socio-economic class may also serve as a cause of inequity, particularly as social deprivation has been associated with overall survival (OS). Adequate sociodemographic representation is required for equitable access and for clinical trials to be informative of the population they serve. The aims of the study were to identify the distribution of patients enrolled into Multiple Myeloma (MM) clinical trials according to social deprivation and understand interactions with race, prognostic markers, and OS. **Methods:** This was a retrospective analysis of MM patients treated in the UK between 2014-2023 from electronic medical records. Social deprivation was assessed using the English Indices of Multiple Deprivation (IMD) ranking, derived from income, employment, health, education, housing barriers, services, crime, and living environment. Comparator data was obtained from the National Cancer Registration and Analysis Service for England (NCRAS, 2006-2015). OS was estimated using Kaplan Meier Curves and correlative analysis by Cox regression models with GraphPad prism V9. **Results:** 580 consecutive patients were grouped by 3 cohorts: standard of care (SOC, n=212), clinical trials (n=355): early phase trials (EPT, Phase I/II, n=103) late phase trials (LPT, Phase II & III, n=252). Median age was 66 years (35-90), M:F ratio was 1.3:1 and had a median of 3 prior lines (0-14). 406 (70%) were White, 80 (13.8%) Black, 40 (6.9%) Asian, 38 (6.6%) Mixed/Other and 16 (2.8%) unknown. There were significantly less patients enrolled into clinical trials (both EPT and LPT) from deprived areas compared to the expected social demographic of MM patients in England (7% (trials) vs 14% (England) for IMD 5, p=< 0.001).

47.6% (n=169) of enrolled patients were referrals from other centres and were from less deprived areas in England (8% trials vs 14% England for IMD 5, p=0.02). Patients in LPT from more deprived areas had an inferior OS than those from more affluent areas (268 months vs 135 months, p= 0.03). Non-white patients in trials were from more deprived areas than white patients (25% IMD 1-2, 43% IMD 4-5 vs 58% IND 1-2m 29% IND 4-5, p=0.018). Patients ≥ 75 with worse social deprivation indices had an inferior OS to those from more affluent areas (median 120m vs 268m p=0.01). **Conclusions:** Patients enrolled into clinical trials were from less socially deprived areas than expected from the distribution of MM in England with referrals favouring higher socio-economic class. As lower socio-economic class impacts overall survival independently of racial group, it is vital that clinical trials enrol from a diverse but balanced socio-economic population. Enrolment should be monitored according to socioeconomic deprivation to ensure there is adequate representation of the geographical population served.

Outcome of pneumocystis jirovecii pneumonia in patients with multiple myeloma

Christine Riedhammer[1], Johannes Duell[1], Christian Kestler[1], Sofie Kadel[1], Johanna Franz[1], Philipp Weis[1], Florian Eisele[1], Xiang Zhou[1], Maximilian Steinhardt[1], Lukas Scheller[1], Julia Mersi[1], Johannes Waldschmidt[1], Hermann Einsele[1], Martin Kortüm[1], Doris Turnwald[1], Güzin Surat[1], Leo Rasche[1]

[1]University Hospital Würzburg

Introduction: Patients with multiple myeloma (MM) are at high risk for infections, including opportunistic infections such as Pneumocystis jirovecii pneumonia (PJP). We conducted a retrospective analysis of patients with MM developing PJP over a six-year period at the University Hospital of Würzburg. **Methods:** Between January 2016 and December 2021, positive results for P. jirovecii in respiratory specimens were retrospectively retrieved through our microbiology database as a quality improvement project in cooperation between the in-house antimicrobial stewardship team (AMS) and the department of hematology. Cases were screened for patients with MM and diagnoses of probable and proven PJP were assessed according to EORTC invasive fungal disease definitions. Patient characteristics, diagnostic findings, disease course, outcome and use of PJP prophylaxis were analyzed in PJP patients. **Results:** From 2016 to 2021, 201 respiratory specimens were tested positive for P. jirovecii. Of these cases, 13 patients with a diagnosis of MM fulfilled the definition of probable PJP. We observed two peaks of PJP incidence, one in patients after autologous or allogeneic transplantation during first line treatment (n = 5), the other in heavily pretreated patients with six or more prior lines of therapy (n = 6). There was high morbidity with nine (69%) patients admitted to the ICU with seven of those (78%) requiring mechanical ventilation, and high mortality (62%, n = 8) within four weeks after PJP diagnosis or due to PJP-related complications, partly complicated by CMV or HSV reactivation (n = 3). Of note, only two of the 13 (15%) patients had received PJP prophylaxis. The main reason for halting prophylaxis with trimethoprim-sulfomethoxazole was grade IV neutropenia. **Conclusions:** PJP can occur in every treatment phase of MM, but mainly affects patients after stem cell transplantation and heavily pretreated patients. Morbidity and mortality in MM patients are significant and even higher than reported for patients with hematologic malignancy in general. Indication for PJP prophylaxis is still incompletely defined, even in HIV-negative patients, but should be assessed individually in patients with risk factors, and halting PJP prophylaxis due to leukopenia needs to be reconsidered. According to current guidelines, prophylaxis use would have been clearly recommended in no more than three (23%) of the 13 patients.

The effect of touch on pain, anxiety and the patient experience during bone marrow biopsies

Anna Schaal[1], Natahsa Dhawan[1], Jacob Pushee[1], Kathleen Broglio[1]

[1]Dartmouth Health

Introduction: Patients with Multiple Myeloma receive a number of bone marrow biopsies over their disease trajectory. Many patients report severe pain and anxiety during bone marrow biopsies (BMBx), but there is no formal consensus on the best approach to managing these symptoms during the procedure. This study aimed to evaluate the effect of simple foot touch on pain and anxiety during BMBx, and describe the patients' experience during the procedure. **Methods:** A single-center randomized control trial using permuted block randomization was conducted at a rural academic cancer center. Nursing assistants without specialized massage training performed simple foot touch on patients in the intervention arm, while the BMBx was performed by advanced practice registered nurses. Patients rated pain and anxiety levels before and after BMBx using the Visual Analog Scale (VAS) and Spielberger State-Trait Anxiety Inventory (STAI) scales, respectively. All participants completed a post-intervention survey about their experience. **Results:** 46 patients were enrolled in the study; 21 in the intervention arm (median age 64.1 years) and 25 in the control arm (median age 64.4 years). There was no difference in the use of anxiolytics (p=0.51) or opioids (p=0.48) during the procedure between the two arms. There were no statistically significant differences on the VAS (p=0.37) or STAI (p=0.40) between the intervention and control arms. Participants in the intervention arm reported more positive feedback and fewer suggestions for improving the patient experience compared to the control arm. **Conclusions:** This is the first study to use an interdisciplinary team approach to evaluate the impact of touch on pain, anxiety, and the patient experience during BMBx. While the intervention did not impact pain or anxiety scores, it may be a feasible, minimal-risk, and no-cost intervention to improve patients' overall experience during BMBx.

47.6% (n=169) of enrolled patients were referrals from other centres and were from less deprived areas in England (8% trials vs 14% England for IMD 5, p=0.02). Patients in LPT from more deprived areas had an inferior OS than those from more affluent areas (268 months vs 135 months, p= 0.03). Introduction: Dietary interventions in multiple myeloma (MM) have recently gained interest due to the interplay between the gut microbiome and tumor biology. However, the extent to which specific nutrients can modify myeloma pathogenesis through interactions with the microbiome and immune system remains to be elucidated. This study investigated the association between dietary patterns of patients with MM and their disease characteristics and treatment outcomes. **Methods:** 62 newly diagnosed MM (NDMM) patients were included in this study between July 2021 and April 2023. NDMM patients reported their dietary habits using a standardized Food Frequency Questionnaire (FFQ). The FFQ data were then analyzed using DGExpert2.0 software. All patients received Dara-VTD induction therapy. Response after four cycles was assessed according to IMWG response criteria. The impact of dietary habits on myeloma pathogenesis was validated using an immunocompetent preclinical model of MM in BALB/c mice. Mice harboring MOPC-315 myeloma grafts were administered both a control diet and a diet supplemented with oleic acid (n=10/group), aiming to replicate the nutritional characteristics observed in NDMM patients. **Results:** When examining the intake of specific fatty acids, the consumption of long-chain unsaturated fatty acids showed a significant correlation with decreased tumor burden in patients classified with International Staging System (ISS) Score I compared to those with ISS Score II and III (Oleic acid: $p< 0.001$, Linoleic acid: $p=0.005$). In contrast, higher carbohydrate intake, driven by sucrose consumption, was linked to elevated ISS scores (ISS I vs. II/III, Carbohydrates: $p=0.007$, Sucrose: $p< 0.001$). In line, a dietary pattern rich in plant-based unsaturated fatty acids and low in sucrose was associated with lower levels of plasma cell infiltration in the bone marrow and reduced paraprotein production. When comparing the dietary intakes of different responder groups, patients who reported lower sucrose consumption and higher intake of unsaturated fatty acids exhibited a higher likelihood of achieving a complete response (CR) (Sucrose: $p< 0.001$ and Oleic acid: $p< 0.001$ for CR vs. non-CR). In the preclinical mouse model, a higher intake of oleic acid was found to confer a significant survival advantage ($p=0.048$). **Conclusions:** Our clinical data suggests that a diet rich in plant-based unsaturated fatty acids, particularly oleic acid, and low in sucrose modulates myeloma biology and positively influences therapy outcomes in NDMM patients. These observations were supported by a preclinical in vivo model. Collectively, our study emphasizes the importance of considering dietary interventions as an indispensable adjunct in supporting and optimizing anti-myeloma therapy.

Introduction: Obesity, low adiponectin, high leptin, high insulin, and diets lacking plant-based foods are all risk factors for plasma cell disorders (PCDs). Therefore, there is a rationale to study a whole food plant-based dietary (WFPBD) intervention to improve modifiable biomarkers and disease trajectory. **Methods:** This was a pilot, single-arm dietary intervention trial of a WFPBD for 12-weeks (w) and health coaching for 24w (by Plantable) in patients (pts) with myeloma precursor disease (MGUS/SMM) and body mass index (BMI) ≥25 (NCT04920084). The primary endpoint was feasibility at 12w; secondary endpoints included metabolic markers (insulin, adiponectin leptin ratio via ELISA at 12w), peripheral blood immune profiling by flow cytometry at 12w, and change in monoclonal (M)-spike concentrations. Rate of change of M-spike per year (y) measured by slope with 95% CI was calculated for up to 20 months (m) pre-intervention and for up to 20m from intervention start (baseline). A p-value for difference in M-spike rates was calculated. **Results:** The median age was 62y with 43% male, 43% non-White, 52% MGUS, 74% obese, and 26% prediabetic/diabetic. At time

Introduction: Obesity, low adiponectin, high leptin, high insulin, and diets lacking plant-based foods are all risk factors for plasma cell disorders (PCDs). Therefore, there is a rationale to study a whole food plant-based dietary (WFPBD) intervention to improve modifiable biomarkers and disease trajectory. **Methods:** This was a pilot, single-arm dietary intervention trial of a WFPBD for 12-weeks (w) and health coaching for 24w (by Plantable) in patients (pts) with myeloma precursor disease (MGUS/SMM) and body mass index (BMI) ≥25 (NCT04920084). The primary endpoint was feasibility at 12w; secondary endpoints included metabolic markers (insulin, adiponectin leptin ratio via ELISA at 12w), peripheral blood immune profiling by flow cytometry at 12w, and change in monoclonal (M)-spike concentrations. Rate of change of M-spike per year (y) measured by slope with 95% CI was calculated for up to 20 months (m) pre-intervention and for up to 20m from intervention start (baseline). A p-value for difference in M-spike rates was calculated. **Results:** The median age was 62y with 43% male, 43% non-White, 52% MGUS, 74% obese, and 26% prediabetic/diabetic. At time

of analysis 20 pts completed the 12w WFPBD intervention and 12 completed 1y of follow-up. The study met feasibility endpoints with 92% median dietary adherence, leading to 7.4% median BMI reduction, improvement in insulin levels (median decrease 0.791 mU/L; p=0.01) and adiponectin leptin (AL) ratio (median increase 0.09; p=0.0002) at 12w. There was a reduction in total innate lymphoid cells (ILCs) (p=0.03) and early NK cells (p=0.03) and an increase in classical monocytes (p=0.04) and CD33+ classical monocytes (p=0.03) (n=14). Among 12 pts followed for 1y, 2 with significant BMI reduction on trial had a statistically significant improvement in the M-spike trajectory: The first patient with Mayo Int Risk IgGκ/IgGλ MGUS achieved a 1y BMI reduction of 19%. Pre-intervention M-spike changed +0.28g/dL/y (6 M-spike values in 20m), and during intervention M-spike changed +0.02g/dL/y (11 M-spike values in 20m); p=0.0001. Baseline M-spike 1.2g/dL and bone marrow plasma cells (BM PC) < 5%; 1.5y BM PC 5-9%. The second patient with IMWG Int Risk IgGκ SMM achieved a 1y BMI reduction 13%. Pre-intervention M-spike changed +0.12g/dL/y (8 M-spike values in 20m), and during intervention M-spike changed -0.05g/dL/y (8 M-spike values in 16m); p=0.009. Baseline M-spike 1.2g/dL and BM PC 20-30%; 1y BM PC 10-15%. Two pts without significant BMI reduction (-4% and -1% at 1y) had rising M-spikes. The remaining 8 pts had median 8% BMI reduction at 1y with stable M-spike levels. **Conclusions:** This is the first trial in PCDs to show a WFPBD improves metabolic profile (BMI, insulin resistance) with an early signal of potentially slowing progression trajectory in a subset of patients. Preliminary immune profiling data supports an effect on ILC and myeloid cell quantity suggestive of diet-mediated immune modulation. Additional analysis in larger sample sets is planned (NCT05640843).

Introduction: Autologous hematopoietic stem cell transplant (AHCT) and chimeric antigen receptor T cells (CAR T) are mainstays of treatment for multiple myeloma (MM), but often have significant and prolonged side effects. Patient-reported outcome (PRO) measures allow for self-reporting of symptoms to the care team and are more comprehensive and reliable than provider-based assessments. Using our center's electronic platform, we aimed to integrate PRO collection into standard-of-care to improve the clinical experience after HCT and CAR T. **Methods:** Patients received the PROMIS-29 survey through a patient portal. Baseline surveys were automatically generated by a chemotherapy order, and follow-up surveys on Day 0 (infusion), weekly for the first month, monthly for the first year, and every 3 months for the second year were generated based on the date of the cell infusion order. Survey responses in pre-identified severe ranges prompted instructions to call the clinician's office and for the clinical team to call the patient. Scores are standardized against US normative population data producing T scores with a mean of 50 and a standard deviation of 10. **Results:** From November 2020 to December 2022, 335 patients underwent a commercial cell therapy at MSK (326 MM, 9 AL amyloidosis, 309 AHCT infusions, 33 CAR T) with overall median age of 64 (range 27-81) and 46% female. At least one survey was completed by 85% of patients with AHCT, with response rates at baseline, Day 0, week 1, week 2, week 3, week 4, and Day 90 of 61%, 38%, 39%, 34%, 38%, 40%, and 36%, respectively. PROMIS-29 physical health summary scores at baseline, Day 0, week 1, week 2, week 3, week 4, and Day 90 were 47 [21-59], 45 [23-59], 44 [22-59], 42 [21-59], 41 [22-59], 42 [22-59], and 46 [29-59], respectively. Mental health summary scores were 51 [31-64], 49 [30-64], 49 [31-64], 48 [27-64], 48 [31-64], 49 [30-64], and 52 [26-64], respectively. For the CAR T patients, 64% answered at least one survey, with response rates at baseline, Day 0, week 1, week 2, week 3, week 4, and Day 90 of 39%, 12%, 21%, 27%, 24%, 21%, and 9%, respectively. PROMIS-29 physical health summary scores at baseline, Day 0, week 1, week 2, week 3, week 4, and Day 90 were 43 [27-57], 40 [27-46], 45 [38-59], 44 [35-59], 51 [35-59], 45 [34-58], and 37 [34-58], respectively. Mental health summary scores were 48 [36-59], 46 [40-50], 49 [45-63], 51 [38-62], 52 [36-64], 52 [48-62], and 45 [39-63], respectively. **Conclusions:** We demonstrate the feasibility of incorporating patient-reported outcomes into standard-of-care practice after AHCT and CAR T. Missing surveys were more common while inpatient, which may be due to toxicity and/or less frequent use of the patient portal while admitted. Additional work is ongoing to improve the response rates at all time points. Importantly, the electronic system allowed us to capture later timepoints when patients have less frequent visits and may be followed locally. Full survey results will be presented.

P-485

Novel observation of the negative effects of persistent chronic opioid use on myeloma survival: a retrospective urban-based cohort study and ongoing prospective HealthTree survey study

Karen Sweiss[1], Pritesh Patel[1], Jennifer Ahlstrom[2], Jay Hydren[2], Jorge Arturo Hurtado Martinez[2], Ana Maria Avila Rodriguez[1], John Quigley[1], Lisa Sharp[3], Gregory Calip[4], Damiano Rondelli[1], Douglas Sborov[5], Craig Hofmeister[6]

of analysis 20 pts completed the 12w WFPBD intervention and 12 completed 1y of follow-up. The study met feasibility endpoints with 92% median dietary adherence, leading to 7.4% median BMI reduction, improvement in insulin levels (median decrease 0.791 mU/L; p=0.01) and adiponectin leptin (AL) ratio (median increase 0.09; p=0.0002) at 12w. There was a reduction in total innate lymphoid cells (ILCs) (p=0.03) and early NK cells (p=0.03) and an increase in classical monocytes (p=0.04) and CD33+ classical monocytes (p=0.03) (n=14). Among 12 pts followed for 1y, 2 with significant BMI reduction on trial had a statistically significant improvement in the M-spike trajectory: The first patient with Mayo Int Risk IgGκ/IgGλ MGUS achieved a 1y BMI reduction of 19%. Pre-intervention M-spike changed +0.28g/dL/y (6 M-spike values in 20m), and during intervention M-spike changed +0.02g/dL/y (11 M-spike values in 20m); p=0.0001. Baseline M-spike 1.2g/dL and bone marrow plasma cells (BM PC) < 5%; 1.5y BM PC 5-9%. The second patient with IMWG Int Risk IgGκ SMM achieved a 1y BMI reduction 13%. Novel observation of the negative effects of persistent chronic opioid use on myeloma survival: a retrospective urban-based cohort study and ongoing prospective HealthTree survey study

Karen Sweiss[1], Pritesh Patel[1], Jennifer Ahlstrom[2], Jay Hydren[2], Jorge Arturo Hurtado Martinez[2], Ana Maria Avila Rodriguez[1], John Quigley[1], Lisa Sharp[3], Gregory Calip[4], Damiano Rondelli[1], Douglas Sborov[5], Craig Hofmeister[6]

[1]University of Illinois at Chicago; [2]HealthTree Foundation; [3]Department of Biobehavioral Nursing Science, University of Illinois at Chicago; [4]Flatiron Health; [5]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, USA; [6]Winship Cancer Institute of Emory University

Introduction: Overuse of opioids has been associated with a significant public health crisis, yet these drugs remain critical as adjunctive treatment for pain in multiple myeloma (MM). Prolonged survival with the use of autologous stem cell transplant (ASCT) and maintenance therapy validates the need to examine chronic opioid use (COU) patterns and the effects of COU on clinical outcomes. **Methods:** A retrospective cohort study of MM patients (n=174) who received ASCT at an urban inner-city transplant center treating mostly Black patients was undertaken. Given the findings of this study, in collaboration with HealthTree Foundation, through a prospective survey-based study, we sought to identify other predictors of COU and gain insight into patient attitudes towards opioids. COU was defined as an active prescription for 3 consecutive months and daily opioid doses were converted to MME. **Results:** At baseline, COU was observed in 92 (52.9%) patients, 27 (29.3%) of whom did not have a history of bone disease. Baseline average MME was 65.3 mg (SD=69.97 mg). COU rates and average MME/day were similar between those with and without bone disease. Previous illicit drug use was associated with higher baseline COU, while use of non-opioid analgesics, being retired, or employed were associated with lower baseline COU. 142 (81.6%) patients received opioids during ASCT, while 105 (60.3%) were discharged on opioids and 72 (41.4%) met criteria for COU at 6 months. In the 105 patients discharged on opioids, COU remained high over time, with 63 (60%) having COU at 6 months after ASCT. In baseline non-opioid users, 30 (36.6%) patients became new opioid users on discharge. Opioid use at hospital discharge was associated with a higher 6-month COU (p=0.008). Median OS in patients with 6-month COU was 48 months vs not reached (p=0.004; Fig 1). 6-month COU independently predicted for worse OS (p=0.006). Given these findings, we developed a 36-item survey addressing demographics like race and SES, disease markers, and experience with pain, use of opioids, opioid risk, and barriers to patient-provider communication. The survey is hosted on the HealthTree Cure Hub (healthtree.org). Between May 15th when the survey went live to May 24th, 230 patients have participated. Surveys will remain open for 3 months with an expected accrual of up to 750 patients. Descriptive data and association between baseline patient/disease-related characteristics and survey answers will be analyzed. **Conclusions:** Here we describe high rates of baseline COU in MM unrelated to the presence of bone disease and highlight a high rate of opiate use after ASCT including a number of new users post-ASCT, which result in ongoing COU at 6 months. We demonstrate a negative impact of COU at 6 months on OS but not on PFS suggesting that opioid-related morbidity may play a role. These data highlight the need to improve our understanding and management of pain in MM. Results from our prospective HealthTree survey study will be presented at the Congress.

Introduction: Elevated body mass index (BMI) is a known risk factor for newly diagnosed multiple myeloma (NDMM); however, the prevalence and clinical significance of BMI changes (gain and loss) during induction therapy in NDMM has not been explored. **Methods:** We conducted a retrospective study of 188 NDMM patients (pts) receiving induction therapy with carfilzomib, lenalidomide and dexamethasone (KRd) from 2016 to 2022 to determine the clinical significance of baseline BMI and trajectory during induction therapy. BMI was collected at baseline and at completion of induction therapy. Pts were divided into – underweight (< 18.5), normal (18.5-24.9) and elevated BMI (≥ 25). Pts were also divided into – weight stable (BMI change < 5%), weight loss (BMI decrease ≥5%) and weight gain (BMI increase ≥5%) based on BMI change post induction from baseline. High risk cytogenetics was defined by the presence of +1q, del(17p), t(4;14), t(14;16) or t(14;20). Progression free survival (PFS) was defined as time from beginning induction therapy to disease progression or death. Univariate analysis was performed by unpaired two-sided t-tests or Cox proportional hazards for survival analyses. Multivariate analysis was performed using Cox proportional hazards regression analysis and model was adjusted for baseline BMI, cytogenetics, age, ECOG and ISS. **Results:** Baseline BMI for pts were 1% underweight, 22% normal, 76% elevated, and 1% unknown. No differences in age, cytogenetics, or ISS stage were noted across baseline BMI categories. During induction, BMI for pts were 14% lost weight, 62% weight stable, and 21% gained weight. For pts with high-risk cytogenetics, 17% lost weight and 18% gained weight, whereas for pts with standard-risk cytogenetics, 13% lost weight and 25% gained weight. Pts with weight gain had a lower median age than weight stable pts (58 years (y) vs 61y, p=0.073) and pts with weight loss had a significantly higher age than weight stable pts (66y vs 61y, p=0.008). On univariate analysis, PFS trended worse for pts with BMI >25 (median PFS NR for both groups, p=0.07). On multivariate analysis, pts with baseline BMI >25 (HR 3.2, p=0.05), high-risk cytogenetics (HR 2.0, p=0.04), and ISS stage 3 disease (HR 2.9, p=0.03) had worse PFS with no difference identified for patient age or ECOG. No differences were observed in post-induction PFS when comparing weight stable pts to those gaining or losing weight (p=0.27). **Conclusions:** Most pts in our dataset had an elevated BMI

Introduction: Elevated body mass index (BMI) is a known risk factor for newly diagnosed multiple myeloma (NDMM); however, the prevalence and clinical significance of BMI changes (gain and loss) during induction therapy in NDMM has not been explored. **Methods:** We conducted a retrospective study of 188 NDMM patients (pts) receiving induction therapy with carfilzomib, lenalidomide and dexamethasone (KRd) from 2016 to 2022 to determine the clinical significance of baseline BMI and trajectory during induction therapy. BMI was collected at baseline and at completion of induction therapy. Pts were divided into – underweight (< 18.5), normal (18.5-24.9) and elevated BMI (≥ 25). Pts were also divided into – weight stable (BMI change < 5%), weight loss (BMI decrease ≥5%) and weight gain (BMI increase ≥5%) based on BMI change post induction from baseline. High risk cytogenetics was defined by the presence of +1q, del(17p), t(4;14), t(14;16) or t(14;20). Progression free survival (PFS) was defined as time from beginning induction therapy to disease progression or death. Univariate analysis was performed by unpaired two-sided t-tests or Cox proportional hazards for survival analyses. Multivariate analysis was performed using Cox proportional hazards regression analysis and model was adjusted for baseline BMI, cytogenetics, age, ECOG and ISS. **Results:** Baseline BMI for pts were 1% underweight, 22% normal, 76% elevated, and 1% unknown. No differences in age, cytogenetics, or ISS stage were noted across baseline BMI categories. During induction, BMI for pts were 14% lost weight, 62% weight stable, and 21% gained weight. For pts with high-risk cytogenetics, 17% lost weight and 18% gained weight, whereas for pts with standard-risk cytogenetics, 13% lost weight and 25% gained weight. Pts with weight gain had a lower median age than weight stable pts (58 years (y) vs 61y, p=0.073) and pts with weight loss had a significantly higher age than weight stable pts (66y vs 61y, p=0.008). On univariate analysis, PFS trended worse for pts with BMI >25 (median PFS NR for both groups, p=0.07). On multivariate analysis, pts with baseline BMI >25 (HR 3.2, p=0.05), high-risk cytogenetics (HR 2.0, p=0.04), and ISS stage 3 disease (HR 2.9, p=0.03) had worse PFS with no difference identified for patient age or ECOG. No differences were observed in post-induction PFS when comparing weight stable pts to those gaining or losing weight (p=0.27). **Conclusions:** Most pts in our dataset had an elevated BMI

that was maintained during induction therapy. The increased risk for weight gain in younger pts and for weight loss in older pts should be considered for pt counseling, although this did not affect PFS. An elevated BMI tracks with inferior PFS. Data on a similar cohort of pts treated with bortezomib, lenalidomide, and dexamethasone along with long-term BMI trajectories post-induction from both cohorts will be presented at the meeting.

Adherence to patient-reported symptom monitoring and subsequent clinical interventions for patients with multiple myeloma in outpatient care: a longitudinal observational study

Ella Willenbacher[1], Wolfgang Willenbacher[1,2], Kelly M de Ligt[3], Stefanie Tipelius[2], Johannes Giesinger[4], Monika Sztankay[4], Sandra Voigt[1,2], Lonneeke van de Polse[5,6,7], Gerhard Rumpold[4], Roman Weger[2], Holzner Bernhard[4], Jens Lehmann[4]

[1]Innsbruck Medical University, Internal Medicine V: Hematology & Oncology, Innsbruck, Austria; [2]syndena GmbH, connect to cure, Innsbruck, Austria; [3]Department of Psychosocial Research and Epidemiology, The Netherlands Cancer Institute, Antoni van Leeuwenhoek, Amsterdam, the Netherlands; [4]University Hospital of Psychiatry II, Medical University of Innsbruck, Innsbruck, Austria; [5]Department of Psychosocial Research and Epidemiology, Department of Medical and Clinical Psychology, Center of Research on Psychological and Somatic Disorders (CoRPS), Tilburg University, Tilburg, the Netherlands; [6]The Netherlands Cancer Institute, Antoni van Leeuwenhoek, Amsterdam, the Netherlands; [7]Department of Research and Development, Netherlands Comprehensive Cancer Organisation, Utrecht, The Netherlands

Introduction: Background: Use of software to monitor Patient-Reported Outcome Measures (PROMs) can improve outcomes for cancer patients receiving anticancer therapy; however, evidence from applications used in routine clinical practice is lacking. **Objective:** We aimed to investigate adherence to, and patient perceptions of a weekly, web-based PROM symptom monitoring in routine clinical practice for patients with Multiple Myeloma. Moreover, we aimed to capture how clinical alerts prompted by the system influenced clinical care. **Methods:** Methods: We conducted a single-center longitudinal observational study to evaluate patient adherence to and perceptions of the PROM monitoring software in routine practice. Patients with Multiple Myeloma remotely completed weekly treatment-specific PROMs to monitor key symptoms via a dedicated web-based platform. Alarming symptoms triggered clinical alerts in the application for the treatment team who could initiate clinical interventions. The primary outcomes were the online assessment completion rate and patients' perceptions of the monitoring program assessed by an evaluation questionnaire. Moreover, clinical alerts prompted by the system and consequential clinical interventions were analyzed. **Results:** Results: Between July 2021 and June 2022, 55 patients were approached for participation; 39 patients participated (24 male [61%], mean age: 63.2 years, SD 9.2). The median assessment completion rate out of all weekly scheduled assessments was 70.3% (IQR 41.2-89.6). Most patients (77%) felt that the healthcare team was better informed on their health status due to the online assessments. Clinical alerts were triggered for 1758/14639 (12.0%) of reported symptoms. For 548/1758 (31.2%) of alerts, the symptom had been registered before and no further action was required; for 348/1758 (19.9%) of alerts, telephone consultation and self-management advice sufficed. Higher-level interventions were seldom needed in response to alerts: referral to a doctor or specialist (88/1758 of alerts, 5.0%), medication changes (22/1758, 1.3%), scheduling additional diagnostics (9/1758, 0.5%), or unplanned emergency visits (7/1758, 0.4%). Most patients (55%) reported the calls in response to alerts gave them "quite a bit" or "very much" of an added feeling of security during therapy. **Conclusions:** Our study shows that high adherence to regular and tailored PROM monitoring can be achieved in routine clinical care. The findings provide valuable insight into how the PROM monitoring program and the clinical alerts and resulting interventions shaped clinical practice. Trial Registration: NCT05036863 (https://clinicaltrials.gov/).

Introduction: syndena is a technology company that provides an innovative Expert-in-the-Loop (EITL) data extraction tool to extract data from electronic health records (EHRs) and medical files. The EITL tool aims to improve patient outcomes in various medical fields e.g. hematology, oncology, neurology, cardiology, and nephrology by generating real-world evidence and preventing misdocumentaions, as well as relieving medical staff of the burden of managing large and complex data sets. **Methods:** Syndena's EITL technology utilizes advanced natural language processing (NLP) and machine learning algorithms to extract relevant data points from unstructured medical records with expert oversight. Healthcare professionals can leverage the technology to gain insights from a broad range of data sources, including lab results and clinical notes. Syndena is already able to structure and find relevant clinical information in EHRs of patients with various medical conditions, making the technology applicable across multiple medical fields. The EITL tool has been successful in extracting and analyzing large and complex data sets from EHRs and medical files at much higher speeds than traditional methods. The data gathered is saved in the Observational Medical Outcomes Partnership Common Data Model (OMOP CDM) automatically, which provides several advantages, including a standardized, widely accepted, data structure. **Results:** syndena's EITL technology can lead to improved patient outcomes by timely generating real-world evidence for all medical fields including hematology. The technology

that was maintained during induction therapy. The increased risk for weight gain in younger pts and for weight loss in older pts should be considered for pt counseling, although this did not affect PFS. An elevated BMI tracks with inferior PFS. Prolonged cytopenia after CAR T-cell therapy in multiple myeloma: results from a prospective comprehensive biomarker study

Xiang Zhou[1], Emilia Stanojkovska[1], Vivien Wagner[1], Christine Riedhammer[1], Xianghui Xiao[1], Mara John[1], Umair Munawar[1], Seungbin Han[1], Johannes Waldschmidt[1], Max Topp[1], Johannes Duell[1], Hermann Einsele[1], Angela Riedel[1], Martin Kortüm[1], Leo Rasche[1]

[1]University Hospital Würzburg

Introduction: The majority of patients treated with CAR-T-cell display unexplained prolonged cytopenia. Our study aimed to explore biomarkers that correlate with cytopenia post CAR-T in multiple myeloma (MM). **Methods:** We prospectively analyzed peripheral blood (PB) of MM patients treated with idecabtagen-vicleucel at these time points: before lymphodepleting (baseline), after CAR-T on d4, 7, 14, 28, and monthly thereafter. Flow cytometry was performed with following markers: CD45, CD3, CD4, CD8, CD62L, CD45RA, CD19, CD14, CD138, CD38 and a BCMA-CAR-detection marker. **Results:** We included a total of 191 sequential PB samples of 32 MM patients. The patients were pretreated with a median of 5 therapy lines (range 2-10). 31 (97%) and 8 (25%) patients underwent autologous and allogeneic stem cell transplant, respectively. Of note, patients with allogeneic stem cell transplant or ≥5 prior therapy lines did not show longer duration of grade ≥3 cytopenia than the remaining patients. However, baseline hemoglobin and platelet count correlated with the duration of grade ≥3 anemia (r=-0.63, P< 0.001) and thrombocytopenia (r=-0.44, P=0.01), respectively. Moreover, the ferritin peak post CAR-T significantly correlated with the duration of grade ≥3 anemia (r=0.65, P< 0.001) and thrombocytopenia (r=0.69, P< 0.001), and the baseline ferritin showed a correlation with the duration of grade ≥3 anemia (r=0.54, P=0.001) and thrombocytopenia (r=0.54, P=0.001). Interestingly, the duration of grade ≥3 lymphopenia significantly correlated with CD4+ (r=0.55, P=0.004), CD8+ T-cell (r=-0.59, P=0.002) frequencies and the CD4+/CD8+ ratio (r=0.55, P=0.004) at baseline. We then divided the patients into two groups: early (< d60) vs prolonged (≥d60) cytopenia. In both groups, high baseline ferritin level indicated severe anemia (< d60: r=-0.50, P< 0.001; ≥d60: r=-0.64, P< 0.001) and thrombocytopenia (< d60: r=-0.61, P< 0.001; ≥d60: r=-0.74, P< 0.001). In the ≥d60 group, the frequency of T-cells showed a negative correlation with hemoglobin (r=-0.52, P=0.001) but a positive correlation with lymphocyte count (r=0.62, P< 0.001), suggesting that prolonged lymphopenia post CAR-T was mainly attributed to the lack of T-cell. The frequency of naïve CD4+ T-cells correlated with neutrophil count (r=0.57, P< 0.001), hemoglobin (r=0.44, P=0.009) and leukocyte count (r=0.48, P=0.004). In prolonged lymphopenia, we found a significant correlation between lymphocyte count and the frequencies of CAR+CD4+ (r=-0.52, P=0.002), CAR+CD8+ (r=0.53, P< 0.001), CAR-CD4+ (r=-0.63, P< 0.001), CAR-CD8+ (r=0.73, P< 0.001) T-cells as well as the ratio of CAR+CD4+/CAR+CD8+ (r=-0.54, P=0.001) and CAR-CD4+/CAR-CD8+ (r=-0.69, P< 0.001). **Conclusions:** Together, high ferritin level and preexisting cytopenia were associated with prolonged cytopenia post CAR-T in MM. Patients with high CD4+/CD8+ ratio, e.g. newly diagnosed MM, are at risk of prolonged T-cell lymphopenia, which may be an issue for infectious complications and later T-cell based immunotherapies.

Real world experience of teclistamab using a prompt management strategy for cytokine release syndrome

Donna Catamero[1], Victoria Dai[2], Mohammad Rattu[1], Sundar Jagannath[3], Cesar Rodriguez[4]

[1]Mount Sinai Hospital; [2]Mount Sinai School of Medicine, New York, NY, USA; [3]Mount Sinai Medical Center, New York, NY, USA; [4]Icahn School of Medicine at Mount Sinai

Introduction: Cytokine release syndrome (CRS) is a systemic inflammatory response commonly associated with T-cell engagers. Teclistamab is the first B-cell maturation antigen bispecific antibody approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In the MajesTEC-1 study, 72.1% of patients experienced CRS; most events were grade 1 (50.3%) but 21.2% were grade 2 and one grade 3. The CRS management guidelines recommended tocilizumab use for grade 2 events but could be considered in certain grade 1. CRS was managed with tocilizumab (36.4%), steroids (8.5%), supplemental oxygen (12.7%), and vasopressors (0.6%) (Moreau et al, NEJM, 2022). Here, we aim to describe the real world experience (RWE), which historically includes

has been tested in various healthcare settings and has been successful in extracting and analyzing large amounts of complex data from source files (EHRs) at high speeds with expert oversight. The EITL tool can also prevent misdocumentations by identifying and correcting data inconsistencies and errors in EHRs and medical files, using plausibility controls. Moreover, the automatic saving of data in the OMOP CDM provides several advantages, including a standardized data structure that allows for efficient and effective data analysis, data normalization, and interoperability across different data sources. **Conclusions:** syndena's EITL technology is a significant advancement in the use of technology to optimize the timely generation of real-world data from large medical data sets and primary source files in a highly compatible fortmat (OMOP CDM) Resulting in standardized data sets that allow for efficient and effective data analysis, data normalization, and interoperability across different data sources. In the ≥d60 group, the frequency of T-cells showed a negative correlation with hemoglobin (r=-0.52, P=0.001) but a positive correlation with lymphocyte count (r=0.62, P< 0.001), suggesting that prolonged lymphopenia post CAR-T was mainly attributed to the lack of T-cell. The frequency of naïve CD4+ T-cells correlated with neutrophil count (r=0.57, P< 0.001), hemoglobin (r=0.44, P=0.009) and leukocyte count (r=0.48, P=0.004). In prolonged lymphopenia, we found a significant correlation between lymphocyte count and the frequencies of CAR+CD4+ (r=-0.52, P=0.002), CAR+CD8+ (r=0.53, P< 0.001), CAR-CD4+ (r=-0.63, P< 0.001), CAR-CD8+ (r=0.73, P< 0.001) T-cells as well as the ratio of CAR+CD4+/CAR+CD8+ (r=-0.54, P=0.001) and CAR-CD4+/CAR-CD8+ (r=-0.69, P< 0.001). **Conclusions:** Together, high ferritin level and preexisting cytopenia were associated with prolonged cytopenia post CAR-T in MM. Patients with high CD4+/CD8+ ratio, e.g. newly diagnosed MM, are at risk of prolonged T-cell lymphopenia, which may be an issue for infectious complications and later T-cell based immunotherapies.

Real world experience of teclistamab using a prompt management strategy for cytokine release syndrome

Donna Catamero[1], Victoria Dai[2], Mohammad Rattu[1], Sundar Jagannath[3], Cesar Rodriguez[4]

[1]Mount Sinai Hospital; [2]Mount Sinai School of Medicine, New York, NY, USA; [3]Mount Sinai Medical Center, New York, NY, USA; [4]Icahn School of Medicine at Mount Sinai

Introduction: Cytokine release syndrome (CRS) is a systemic inflammatory response commonly associated with T-cell engagers. Teclistamab is the first B-cell maturation antigen bispecific antibody approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In the MajesTEC-1 study, 72.1% of patients experienced CRS; most events were grade 1 (50.3%) but 21.2% were grade 2 and one grade 3. The CRS management guidelines recommended tocilizumab use for grade 2 events but could be considered in certain grade 1. CRS was managed with tocilizumab (36.4%), steroids (8.5%), supplemental oxygen (12.7%), and vasopressors (0.6%) (Moreau et al, NEJM, 2022). Here, we aim to describe the real world experience (RWE), which historically includes

has been tested in various healthcare settings and has been successful in extracting and analyzing large amounts of complex data from source files (EHRs) at high speeds with expert oversight. The EITL tool can also prevent misdocumentations by identifying and correcting data inconsistencies and errors in EHRs and medical files, using plausibility controls. Moreover, the automatic saving of data in the OMOP CDM provides several advantages, including a standardized data structure that allows for efficient and effective data analysis, data normalization, and interoperability across different data sources. **Conclusions:** syndena's EITL technology is a significant advancement in the use of technology to optimize the timely generation of real-world data from large medical data sets and primary source files in a highly compatible fortmat (OMOP CDM) Resulting in standardized data sets that allow for efficient and effective data analysis, data normalization, and interoperability across different data sources. Syndena's EITL technology has demonstrated its potential to improve QoL and understanding of outcomes across multiple medical fields. By facilitating personalized medicine and improving clinical trial design, the EITL tool can inform healthcare policies and drive evidence-based decision-making. Fubased data sets. rthermore syntetic data can easily be generated from EITL based data sets.

Prolonged cytopenia after CAR T-cell therapy in multiple myeloma: results from a prospective comprehensive biomarker study

Xiang Zhou[1], Emilia Stanojkovska[1], Vivien Wagner[1], Christine Riedhammer[1], Xianghui Xiao[1], Mara John[1], Umair Munawar[1], Seungbin Han[1], Johannes Waldschmidt[1], Max Topp[1], Johannes Duell[1], Hermann Einsele[1], Angela Riedel[1], Martin Kortüm[1], Leo Rasche[1]

[1]University Hospital Würzburg

Introduction: The majority of patients treated with CAR-T-cell display unexplained prolonged cytopenia. Our study aimed to explore biomarkers that correlate with cytopenia post CAR-T in multiple myeloma (MM). **Methods:** We prospectively analyzed peripheral blood (PB) of MM patients treated with idecabtagen-vicleucel at these time points: before lymphodepleting (baseline), after CAR-T on d4, 7, 14, 28, and monthly thereafter. Flow cytometry was performed with following markers: CD45, CD3, CD4, CD8, CD62L, CD45RA, CD19, CD14, CD138, CD38 and a BCMA-CAR-detection marker. **Results:** We included a total of 191 sequential PB samples of 32 MM patients. The patients were pretreated with a median of 5 therapy lines (range 2-10). 31 (97%) and 8 (25%) patients underwent autologous and allogeneic stem cell transplant, respectively. Of note, patients with allogeneic stem cell transplant or ≥5 prior therapy lines did not show longer duration of grade ≥3 cytopenia than the remaining patients. However, baseline hemoglobin and platelet count correlated with the duration of grade ≥3 anemia (r=-0.63, P< 0.001) and thrombocytopenia (r=-0.44, P=0.01), respectively. Moreover, the ferritin peak post CAR-T significantly correlated with the duration of grade ≥3 anemia (r=0.65, P< 0.001) and thrombocytopenia (r=0.69, P< 0.001), and the baseline ferritin showed a correlation with the duration of grade ≥3 anemia (r=0.54, P=0.001) and thrombocytopenia (r=0.54, P=0.001). Interestingly, the duration of grade ≥3 lymphopenia significantly correlated with CD4+ (r=0.55, P=0.004), CD8+ T-cell (r=-0.59, P=0.002) frequencies and the CD4+/CD8+ ratio (r=0.55, P=0.004) at baseline. We then divided the patients into two groups: early (< d60) vs prolonged (≥d60) cytopenia. In both groups, high baseline ferritin level indicated severe anemia (< d60: r=-0.50, P< 0.001; ≥d60: r=-0.64, P< 0.001) and thrombocytopenia (< d60: r=-0.61, P< 0.001; ≥d60: r=-0.74, P< 0.001). In the ≥d60 group, the frequency of T-cells showed a negative correlation with hemoglobin (r=-0.52, P=0.001) but a positive correlation with lymphocyte count (r=0.62, P< 0.001), suggesting that prolonged lymphopenia post CAR-T was mainly attributed to the lack of T-cell. The frequency of naïve CD4+ T-cells correlated with neutrophil count (r=0.57, P< 0.001), hemoglobin (r=0.44, P=0.009) and leukocyte count (r=0.48, P=0.004). In prolonged lymphopenia, we found a significant correlation between lymphocyte count and the frequencies of CAR+CD4+ (r=-0.52, P=0.002), CAR+CD8+ (r=0.53, P< 0.001), CAR-CD4+ (r=-0.63, P< 0.001), CAR-CD8+ (r=0.73, P< 0.001) T-cells as well as the ratio of CAR+CD4+/CAR+CD8+ (r=-0.54, P=0.001) and CAR-CD4+/CAR-CD8+ (r=-0.69, P< 0.001). **Conclusions:** Together, high ferritin level and preexisting cytopenia were associated with prolonged cytopenia post CAR-T in MM. Patients with high CD4+/CD8+ ratio, e.g. newly diagnosed MM, are at risk of prolonged T-cell lymphopenia, which may be an issue for infectious complications and later T-cell based immunotherapies.

Real world experience of teclistamab using a prompt management strategy for cytokine release syndrome

Donna Catamero[1], Victoria Dai[2], Mohammad Rattu[1], Sundar Jagannath[3], Cesar Rodriguez[4]

[1]Mount Sinai Hospital; [2]Mount Sinai School of Medicine, New York, NY, USA; [3]Mount Sinai Medical Center, New York, NY, USA; [4]Icahn School of Medicine at Mount Sinai

Introduction: Cytokine release syndrome (CRS) is a systemic inflammatory response commonly associated with T-cell engagers. Teclistamab is the first B-cell maturation antigen bispecific antibody approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In the MajesTEC-1 study, 72.1% of patients experienced CRS; most events were grade 1 (50.3%) but 21.2% were grade 2 and one grade 3. The CRS management guidelines recommended tocilizumab use for grade 2 events but could be considered in certain grade 1. CRS was managed with tocilizumab (36.4%), steroids (8.5%), supplemental oxygen (12.7%), and vasopressors (0.6%) (Moreau et al, NEJM, 2022). Here, we aim to describe the real world experience (RWE), which historically includes

patients who would not have been eligible for clinical trials, using a more proactive teclistamab use to manage CRS. **Methods:** This retrospective study analyzed data from RRMM patients who were treated with commercial teclistamab at our center as of December 1, 2022. Patients were identified using the pharmacy's database and data was abstracted from electronic medical records. Information on treatment administration, disease profile, toxicities including CRS and management were collected. Per institutional policy, the use of tocilizumab was used at first onset of fever during the initial step-up doses of teclistamab. **Results:** As of May 30, 2023, 35 patients were treated. Data from 26 patients has been analyzed and data from all patients will be presented at the meeting. Overall, 78% of patients experienced any grade CRS. Among patients with CRS, 85% of patients experienced a grade 1 CRS and 15% had a grade 2. There were no grade 3 events. Seventy percent of CRS events occurred with step-up dose (SUD) 1, 35% with SUD2 and 20% with cycle 1 day 1. Two patients had CRS after cycle 1 day 1. Of these two, one had plasma cell leukemia and the other significant extramedullary disease. All patients presented with fever (38.5C) and were administered tocilizumab and acetaminophen with first at first occurrence. Other supportive measures included steroids (25%) and intravenous fluids (5%). Four patients had subsequent CRS after initial dose of tocilizumab; all events were grade 1. **Conclusions:** Our RWE is comparable to the MajesTEC-1 in terms of overall CRS incidence, despite a patient population which would not have been eligible for clinical. We expected this population to be more vulnerable to higher grades of CRS yet data showed a more benign course. We attribute this to aggressively managing CRS with use of tocilizumab and acetaminophen at first sign of CRS to prevent further escalation. CRS episodes were seen less in subsequent teclistamab doses and severity was never above grade 1, making it more manageable in a potential outpatient setting. A proactive management approach to reduce severity and increase predictability could facilitate adoption of outpatient when treatment and escalation are needed, to ensure successful administration of teclistamab.

Characteristics of multiple myeloma patients with central nervous system involvement

Jessica Chen[1], Tiffany Richards[1], Christy Allen[1], Yue Jiang[1], Courtney Bendig[1], Ashley Morphey[1], Elizabeth Cuellar[1], Sarah Knight[1], Efe Ighovoyivwi[1], Rebecca Lu[1], Pei Lin[1], Behrang Amini[1], Mahmoud Gaballa[1], Hans Lee[1], Elisabet Manasanch[1], Krina Patel[1], Sheeba Thomas[1], Jing Christine Ye[1,2], Bouthain Dabaja[1], Chelsea Pinnix[1], Penny Fang[1], Jill Gunther[1], Robert Orlowski[1], Donna Weber[1], Melody Becnel[1]

[1]MD Anderson Cancer Center; [2]University of Michigan, Rogel Cancer Center, Ann Arbor, MI, USA (during study)

Introduction: Despite advances in multiple myeloma (MM) treatment, systemic therapy alone for central nervous system (CNS) MM is often ineffective. While intrathecal (IT) chemo with cytarabine, methotrexate or topotecan, and/or radiation may result in transient responses, the median overall survival (OS) for patients with CNS involvement ranges between 2-10 months. **Methods:** This single center retrospective review of patients (pts) with CNS MM (diagnosed as CSF plasma cells, parenchymal and/or leptomeningeal disease (LMD) on imaging) from 2016-2023 were identified in the medical records. We aim to identify factors associated with development of CNS MM, overall survival from initial MM diagnosis (dx) and from onset of CNS, and progression free survival (PFS). Further analyses will include patients with radiographic findings of CNS involvement and patients with extramedullary disease (EMD). Pts with EMD will be analyzed to identify factors associated with EMD, OS, and development of CNS disease. **Results:** 35 pts were identified who had clonal plasma cells in the CSF: 15 (42.8%) were White, 12 (34.2%) were Hispanic, 6 (17.1%) were Black, and 2 (5.7%) were Asian. 54.2% were males, and 62.8% were kappa predominant. Median age at diagnosis was 57 (range 25-77). Among 27 pts with R-ISS available, 4 (14%) had stage I disease, 14 (51%) had Stage II, and 9 (33%) had stage III. Of 20 evaluable patients with FISH panels, we noted deletion 13 (70%), gain of CKS1B (70%), t(4;14) (35%), deletion of 17p (15%), and t(11;14) (10%). Of the 14 pts with gain of CKS1B, 11 also had deletion 13. Most common symptoms included weakness of the extremities and/or difficulty ambulating (32%), facial or extremity numbness (26%), altered mental status (26%), headaches (17.6%), diplopia (14.7%), and seizure (8.8%). 21 pts (60%) presented with EMD prior to presenting with CNS disease (median time to CNS involvement after EMD was 35-months [range 1-35]). The most common sites for EMD included pleura/lung (8 patients), adenopathy (7 patients), pancreas (6 patients), GI tract (4 patients), subcutaneous tissues (3 patients), and intramuscular (2 patients) with all but one having multiple sites of disease. The median PFS to first line therapy was 18 months (range 1-97 months) and the median time from MM diagnosis to CNS disease was 38 months (range 1-99 months). The median OS was 41 months (range 5-120months). Median OS after CNS diagnosis was 3 months (range 1-51 months). **Conclusions:** In our analysis, pts with CNS MM had a poor prognosis with a median OS of 3 months from the time of CNS diagnosis, highlighting the need for more effective therapy. In this group of patients, the PFS to first line therapy was short, despite only 9 patients having high risk disease, solidifying that EMD should be treated as a high risk feature independent of other factors. Additionally, 60% presented with EMD prior to CNS involvement. Further analysis of pts with EMD is warranted, which may include CNS prophylaxis in certain patients with EMD.

Impact of myeloma and amyloidosis on young patients

Emma Dowling[1], Nuno Correia[2], Ashutosh Wechelaker[3]

[1]HCA Healthcare UK; [2]HCA healthcare at UCH, Private Care; [3]National Amyloidosis Centre, University College London, London, United Kingdom

Introduction: Multiple myeloma (MM) and Amyloid (AL) is a treatable plasma cell cancer with no cure1. The average age of

diagnosis of these malignancies is 70 years old2. The overall survival of younger patients is drastically longer than of their older cohorts3, and with this comes a unique set of challenges and obstacles to live with at such a young age. The young MM and AL patients and their survivorship is not a common area of exploration. We performed this study to understand the impact of these diagnoses on our patients from a physical, psychological and social perspective and assess their need for increased education and psychological support as a result. We asked patients to retrospectively grade their top areas of concern at time of diagnosis and then further grade these concerns again in the present day. **Methods:** An online, questionnaire designed by the authors via Microsoft Forms. This questionnaire surveyed MM/AL patients who were diagnosed at the age of 55 or under. **Results:** We surveyed 57 young patients (under the age of 55) and obtained 29 completed surveys, in a period of 7days. We expect more surveys to be completed. Our patients average age at diagnosis was 45, ranging from 30 to 55 years of age. We obtained responses from 19 male and 10 female patients. Only 4 (14%) had heard of the disease before diagnosis. When questioned on their biggest fear the overwhelming response from these patients was early death. Their biggest areas of concern at diagnosis were "anxiety about their future" and "the impact on their children's lives". And although these concerns are still present today, they are reduced in comparison to the time of diagnosis. Interestingly 13 (45%) of our patients have not received any counselling support, of these some site "exercise, meditation, family and friends, myeloma nurse and support groups", as their strategy to cope with their illness. Some patients have developed comorbidities throughout their treatment journey, mainly 5 (17%) with cardiac complications and 4 (14%) with thyroid related issues. **Conclusions:** This survey is a unique opportunity to explore the areas of most concern of this young patient population. Many of these patients will live for many years, meaning more focus is needed on survivorship and quality of life. From our findings we can conclude the disease has an enormous psychological impact on patients' lives. Their greatest fears are dying young and not seeing their kids grow up. Conversely, despite this huge impact on their mental health, only half of them have received counselling. This highlights space for improvement and perhaps counselling could be standardised as part of their plan of care from diagnosis. With greater treatment options and longer life expectancy, this patient group, requires more tailored specialised care to adequately meet their unique needs.

Introduction: Glucocorticosteroids (steroids), central to the treatment of multiple myeloma (MM), have multiple deleterious side effects (SE). Our team found that disturbed sleep was the most frequently reported SE, identified in up to 95% of patients (King et al 2019), with 67% of patients reporting severe sleep disturbances. This pilot study, funded by a grant from Sydney Blood Cancer Institute, is the first to characterise sleep disturbances associated with steroid treatment in MM using objective measures of sleep quality. **Methods:** 10 MM participants currently taking steroids for MM, with associated disturbed sleep and an ECOG ≤ 2 were recruited. Participants were assessed for risk of obstructive sleep apnoea (OSA), and those found to be at high risk of OSA excluded from the study. Sleep duration, sleep efficiency and wake bouts were measured over the three weeks of monitoring using actigraphy, a validated method of objective long-term sleep monitoring using a watch-like device, and sleep diaries to document subjective sleep experience. Actigraphy data was analysed in a blinded fashion, utilising light, and activity levels to determine attempted sleep periods, with sleep diaries to confirm these. Semi-structured interviews were undertaken post monitoring period. **Results:** To date 8 participants have been recruited, 4 male and 4 female. Enrolled participants were median of 60.5 (53-71) years of age, receiving median of 100 mg range (24-160) of dexamethasone per cycle of treatment and had received up to 4 lines of previous treatment. We report actigraphy data on 3 participants with completed data. Sleep duration was reduced in 2/3 of participants by 33%, and 43% on dexamethasone nights. There was a reduction in average sleep efficiency (% time asleep when in bed) and a lowering of wake bouts with dexamethasone, 83.0% vs 75.3%, and 29.5 vs 21.0, respectively. The average fragmentation index (a measure of sleep disturbance) slightly increased from 17.2 to 19.8 on dexamethasone nights. **Conclusions:** This pilot study has shown the approach to data collection is feasible. It is the first study to objectively characterise sleep disturbances associated with dexamethasone treatment in MM. Our preliminary results indicate a reduction in sleep duration and sleep efficiency on nights participants took dexamethasone. Sleep was more disturbed on these nights, with less, though longer, periods of wakefulness. Data on the full cohort is pending and will be further informed by the qualitative interviews.

Introduction: Autologous stem cell transplantation (ASCT) is offered as a front-line treatment for eligible multiple myeloma

diagnosis of these malignancies is 70 years old2. The overall survival of younger patients is drastically longer than of their older cohorts3, and with this comes a unique set of challenges and obstacles to live with at such a young age. The young MM and AL patients and their survivorship is not a common area of exploration. We performed this study to understand the impact of these diagnoses on our patients from a physical, psychological and social perspective and assess their need for increased education and psychological support as a result. We asked patients to retrospectively grade their top areas of concern at time of diagnosis and then further grade these concerns again in the present day. **Methods:** An online, questionnaire designed by the authors via Microsoft Forms. This questionnaire surveyed MM/AL patients who were diagnosed at the age of 55 or under. **Results:** We surveyed 57 young patients (under the age of 55) and obtained 29 completed surveys, in a period of 7days. We expect more surveys to be completed. Our patients average age at diagnosis was 45, ranging from 30 to 55 years of age. We obtained responses from 19 male and 10 female patients. Only 4 (14%) had heard of the disease before diagnosis. When questioned on their biggest fear the overwhelming response from these patients was early death. Their biggest areas of concern at diagnosis were "anxiety about their future" and "the impact on their children's lives". And although these concerns are still present today, they are reduced in comparison to the time of diagnosis. Interestingly 13 (45%) of our patients have not received any counselling support, of these some site "exercise, meditation, family and friends, myeloma nurse and support groups", as their strategy to cope with their illness. Some patients have developed comorbidities throughout their treatment journey, mainly 5 (17%) with cardiac complications and 4 (14%) with thyroid related issues. **Conclusions:** This survey is a unique opportunity to explore the areas of most concern of this young patient population. Many of these patients will live for many years, meaning more focus is needed on survivorship and quality of life. From our findings we can conclude the disease has an enormous psychological impact on patients' lives. Their greatest fears are dying young and not seeing their kids grow up. Conversely, despite this huge impact on their mental health, only half of them have received counselling. This highlights space for improvement and perhaps counselling could be standardised as part of their plan of care from diagnosis. With greater treatment options and longer life expectancy, this patient group, requires more tailored specialised care to adequately meet their unique needs.

Introduction: Autologous stem cell transplantation (ASCT) is offered as a front-line treatment for eligible multiple myeloma

(MM) patients due to its efficacy at increasing progression-free survival. However, it is also associated with high symptom burden and reduced quality of life (QoL) which are greatest in the first-month post-ASCT. Whilst most symptoms improve by the third month, pain and reduced QoL remain prevalent for up to one year. Indicating a need for supportive care to aid recovery. Patients who complete exercise programs pre and post-ASCT report a greater trajectory of recovery. Therefore, we evaluated the implementation of specialist physiotherapy provision introduced at 100 days (D100) post-transplant aimed to optimize patient recovery through exercise. **Methods:** At University College London Hospital we conducted a service improvement project within the MM ASCT pathway. Patients seen within the D100 clinic between November 2021–December 2022 were assessed by a specialist MM physiotherapist and prescribed tailored exercises. Outcomes included a measure of functional capacity (1-minute timed sit-to-stand test (STS-1min)), self-reported (PA) (GODIN), VAS for pain (0=no pain to 10=worst pain) and QoL (EQ5D-5L). These measures were collected at their D100 appointment (baseline) and 3 months post-D100 appointment (follow-up). In addition, an anonymous patient satisfaction survey was emailed to consenting patients upon completion of the programme. **Results:** Over 1 year, 78 patients were assessed at baseline (68% male; mean age 58 years (range 42-77)). 13/78 (17%) had previous surgery and 27/78 (35%) had worn a spinal brace for MM-related bone disease. 38 patients completed a follow-up assessment within the funded time frame of the project and were included in the analysis. There was a significant and clinically meaningful increase in functional capacity. Mean STS-1min score increased by 13 repetitions (Baseline: 23 reps, Follow-up: 36 reps; p<.001). Significant improvements were found in PA levels (Median mod-vig PA Baseline: 0 mins per week [IQR 0–0] Follow-up: 180 mins per week [IQR 50–270] p<.001). Pain significantly reduced from 4/10 to 1/10 (p<.0 01). From baseline to follow-up, 18 (75%) of patients had an improved QoL status, 3 (13%) had a mixed change and 3 (13%) had no change. QoL domains related to mobility and pain showed the largest improvements. The patient satisfaction questionnaire was returned by 31/38 (81%) patients, 91% strongly agreed and 9% agreed that they felt more confident to self-manage their functional concerns after their physiotherapy consultation and it had been a valuable part of their recovery. There were no adverse events. **Conclusions:** This service evaluation demonstrates the benefit of a physiotherapist assessment and individually tailored rehabilitation input as part of the ASCT pathway in MM. Results show that rehabilitation post-transplant is safe, improves patients functional capacity, PA levels, pain and QoL with high levels of patient satisfaction.

'Just one thing': patient, nurse and haematologist priorities for myeloma services

Monica Morris[1], Suzanne Renwick[1], Jessica Turner[1]

[1]Myeloma UK

Introduction: Myeloma services that are responsive to individual need are vital to supporting a positive patient experience. The Myeloma UK Clinical Service Excellence Programme (CSEP) supports hospitals to deliver optimum care to myeloma patients through a process of assessment and accreditation. During CSEP, patient feedback is gathered using a survey that includes the question 'If you could change one thing about your myeloma treatment and care, what would it be?' An earlier analysis of responses to this question prompted the authors to pose a similar question to healthcare professionals (HCPs). The aim was to compare responses to further inform how service development could improve patient experience. **Methods:** Using email and Microsoft Teams calls, feedback was collated from specialist nurses and haematologists in reply to the question 'If you could change one thing about your myeloma service, what would it be?' Further responses from patients collected since the first analysis were added to the existing patient data and re-analysed. **Results:** Between 2015 and 2023, over 1000 responses were gathered from patients, nurses and haematologists from more than 60 hospitals. Patient responses including negative feedback or suggested changes were included in the analysis, as were all HCP responses. As a result, over 500 responses were analysed and thematically organised. HCP responses were grouped into seven themes: clinic waiting time, community treatment delivery, dedicated hospital space, holistic care, research and treatment, staffing, and other resources integral to the service. Patient responses were grouped into eight themes: clinic and pharmacy waiting time, communication, continuity of care, coordination of care, holistic care, hospital facilities, travel, and access to treatment. Themes from patients and HCPs on issues of hospital space and facilities, waiting times, staffing, resources, and travel for treatment and care, intersect to highlight systemic logistical problems within UK health services. Themes of holistic care, community delivery, communication and continuity of care suggest the need for services to be more patient-centred for this often elderly, frail, patient cohort. For HCPs, having adequate staffing (particularly clinical nurse specialists) was the key concern. Pressure on nurse time reflects recent advances in myeloma treatment and survival which has translated into larger caseloads and more patients being on treatment needing review. Consequently, patients are impacted by longer waits and HCPs struggle to manage patients' individual needs. **Conclusions:** Broadening this analysis to include HCPs provides increased insight into which service changes are needed to improve patient experience. By combining the voice of both patients and the staff caring for them, a stronger case for change can be made.

Consequently, patients are impacted by longer waits and HCPs struggle to manage patients' individual needs. **Conclusions:** Broadening this analysis to include HCPs provides increased insight into which service changes are needed to improve patient experience. By combining the voice of both patients and the staff caring for them, a stronger case for change can be made.

Introduction: Talquetamab is a T-cell redirecting bispecific antibody that targets a novel antigen, GPRC5D, on myeloma cells. Data from the MonumenTAL-1 study in patients with relapsed/refractory multiple myeloma (RRMM) showed overall response rates of >71% and durable responses at talquetamab weekly (QW) and every other week (Q2W) dosing. Talquetamab is associated with a distinct group of GPRC5D-related adverse events (AEs), including dermatologic (skin and nail) AEs. Here we describe the presentation and management of dermatologic AEs in patients from MonumenTAL-1 treated at a single center. **Methods:** MonumenTAL-1 (NCT03399799/NCT04634552) is an open-label, single-arm, phase 1/2 study of patients who had progressed on or could not tolerate established MM therapies (phase 1) or were exposed to ≥3 prior lines of therapy (phase 2; including a proteasome inhibitor, immunomodulatory drug, and anti-CD38 antibody). Patients included in the current analysis received subcutaneous talquetamab at the recommended phase 2 doses (RP2Ds) of 0.4 mg/kg QW or 0.8 mg/kg Q2W. AEs were graded according to CTCAE v4.03. **Results:** Talquetamab has demonstrated 12-month PFS rates of 35% and 54% and OS rates of 76% and 77% with QW and Q2W dosing in the MonumenTAL-1 study. Dermatologic AEs in MonumenTAL-1 included skin (eg, dry skin, exfoliation), rash, and nail (eg, thinning, peeling) AEs. Among patients (N=24) receiving the talquetamab RP2Ds in our center, 87.5% had skin (grade 3, 4.2%), 45.8% had rash (grade 3, 33.3%), and 58.3% had nail (grade 3, 0%) AEs. Median time to onset of dermatologic AEs was ~4.6–15 weeks following first talquetamab dose. Most dermatologic AEs resolved, except nail AEs: only 28.6% of events resolved, with a median time to resolution of ~16 weeks; this is potentially due to timing of nail regrowth. Management of dermatologic AEs included a heavy moisturizer for general dryness; ammonium lactate 12% lotion twice daily (BID) for hand and foot peeling; loratadine 10 mg oral tablet daily for 3–5 days post dose and triamcinolone 0.1% cream BID for pruritus, injection-site reaction, and rash; and nail hardeners, topical vitamin E oil, and triamcinolone 0.025% ointment for nail thinning and peeling. Methylprednisolone taper and betamethasone 0.05% cream BID were considered for grade 3 rash. Other grade 3 dermatologic AE mitigation approaches included dose holds. In general, patients were encouraged to take short lukewarm showers, use a heavy lotion or moisturizer throughout the day on skin and cuticles, and keep nails short and clean. Patients considered the AEs generally tolerable, and no patient from our center discontinued the study due to dermatologic AEs. **Conclusions:** Talquetamab is an effective therapy for patients with RRMM. Skin and nail AEs are common but are primarily low grade with no discontinuations. Appropriate management, education, and supportive care ensure that patients can stay on treatment to receive optimal benefit from talquetamab.

Update to nursing care pathway for infection risk and prophylaxis in RRMM receiving novel therapy

Carrie Bellerive[1], Matthew Whooley[1], Sarah Stice-Goff[1], Steven Bleak[1], Kristi Bailey[1], Briana Peterson[1], Zachary Francom[1], Ishwarya Balasubramanian[1], Charlotte Wagner[2], Baylee Bryan[2], Kelley Julian[2], Lindsay Maxwell[3], Meghan Vigil[3], Samuel Shewan[3], Mary Steinbach[3], Hannah Imlay[4], Douglas Sborov[1]

[1]Huntsman Cancer Institute at the University of Utah; [2]Department of Pharmacy, University of Utah Hospitals and Clinics, Huntsman Cancer Institute; [3]Division of Hematology, Department of Internal Medicine, University of Utah Huntsman Cancer Institute; [4]Division of Infectious Diseases, Department of Internal Medicine, University of Utah Huntsman Cancer Institute

Introduction: New BCMA-targeted drugs have been FDA approved for relapsed and refractory multiple myeloma (RRMM). These new treatments provide excellent responses but also have side effects of prolonged neutropenia and increased risk for infection. Pneumocystis jirovecii pneumonia (PJP) fungal infection can cause life-threatening pneumonia in MM. Similarly, cytomegalovirus (CMV) is now more commonly seen in RRMM. In 2022, nurses at the Huntsman Cancer Institute (HCI) developed a nursing care pathway for monitoring PJP risk in patients receiving stem cell transplants, Chimeric antigen receptor T-cell (CarT) therapy, and bispecific antibodies (BsABs). Herein we present our experience after updating the nursing care pathway to reflect new recommendations and real-world exposures. **Methods:** A rolling report of MM patients post-autologous transplant, post-CarT, or receiving BsABs was updated to include patient information for monitoring (including CD4 count, CMV NAAT, prophylaxis, and next lab appointment). Based on the report, nurses either (1) begin monitoring CD4 and/or CMV, (2) discontinue monitoring CD4 and/or CMV, (3) begin PJP prophylaxis (CD4 200 for two consecutive months). Monitoring BsAbs patients for CMV via NAAT titers was added to the report and algorithm in October 2022. If CMV NAAT is detected but not quantifiable, weekly monitoring is performed until undetected. If CMV titer is quantifiable at >100 IU/mL, appropriate induction treatment is initiated with weekly monitoring. Therapy is continued until CMV NAAT is undetected or until 14 days. If a patient on CMV treatment has no clinical symptoms, therapy is discontinued once CMV NAAT is undetectable. Monthly monitoring of these patients continues. If CMV turns positive and the patient is symptomatic, an ID consult is initiated to streamline intervention(s). **Results:** After closer monitoring of high-risk patients for a year, HCI has had no new PJP infections. Of the patients meeting the need for CMV viral load monitoring per algorithm, twelve are on bispecific therapy and two are post-CarT and received >1 dose of tocilizumab or dexamethasone (≥ 10 mg for 3 days) with baseline CMV IgG seropositivity. Only 14% (1 out of 14) required induction

Introduction: New BCMA-targeted drugs have been FDA approved for relapsed and refractory multiple myeloma (RRMM). These new treatments provide excellent responses but also have side effects of prolonged neutropenia and increased risk for infection. Pneumocystis jirovecii pneumonia (PJP) fungal infection can cause life-threatening pneumonia in MM. Similarly, cytomegalovirus (CMV) is now more commonly seen in RRMM. In 2022, nurses at the Huntsman Cancer Institute (HCI) developed a nursing care pathway for monitoring PJP risk in patients receiving stem cell transplants, Chimeric antigen receptor T-cell (CarT) therapy, and bispecific antibodies (BsABs). Herein we present our experience after updating the nursing care pathway to reflect new recommendations and real-world exposures. **Methods:** A rolling report of MM patients post-autologous transplant, post-CarT, or receiving BsABs was updated to include patient information for monitoring (including CD4 count, CMV NAAT, prophylaxis, and next lab appointment). Based on the report, nurses either (1) begin monitoring CD4 and/or CMV, (2) discontinue monitoring CD4 and/or CMV, (3) begin PJP prophylaxis (CD4 200 for two consecutive months). Monitoring BsAbs patients for CMV via NAAT titers was added to the report and algorithm in October 2022. If CMV NAAT is detected but not quantifiable, weekly monitoring is performed until undetected. If CMV titer is quantifiable at >100 IU/mL, appropriate induction treatment is initiated with weekly monitoring. Therapy is continued until CMV NAAT is undetected or until 14 days. If a patient on CMV treatment has no clinical symptoms, therapy is discontinued once CMV NAAT is undetectable. Monthly monitoring of these patients continues. If CMV turns positive and the patient is symptomatic, an ID consult is initiated to streamline intervention(s). **Results:** After closer monitoring of high-risk patients for a year, HCI has had no new PJP infections. Of the patients meeting the need for CMV viral load monitoring per algorithm, twelve are on bispecific therapy and two are post-CarT and received >1 dose of tocilizumab or dexamethasone (≥ 10 mg for 3 days) with baseline CMV IgG seropositivity. Only 14% (1 out of 14) required induction

treatment, and remains on maintenance therapy for ongoing CMV viremia. This asymptomatic patient was on a BsAB clinical trial; the other patients being surveilled did not cross the treatment threshold. **Conclusions:** Given the evolution of safety data and monitoring for novel treatments in RRMM, we updated our algorithm. As a result, nursing practice has elevated to quickly identifying patients at highest risk for developing PJP and CMV viremia and intervening appropriately. Prolonged treatment holds have been reduced due to this algorithm as evidenced by no new PJP infections and a small proportion of patients with mild CMV. In the future, we hope to refine best practices for CD4 and CMV titer monitoring and frequency in RRMM.

Clinical trial enrollment at a national cancer institute cancer center in the US Mountain West

Carrie Bellerive[1], Kelley Julian[1], Ryan Lombardi[1], Catherine Cromar[1], Mary Steinbach[1], Douglas Sborov[1]

[1]University of Utah, Huntsman Cancer Institute

Introduction: Despite advances in the treatment of multiple myeloma (MM) through clinical trials, equitable trial enrollment which accurately reflects the landscape of the disease remains challenging. Research in MM has uncovered disparities with regard to patient age, race/ethnicity, rural-urban residence, socioeconomic status, insurance type, and underrepresentation in clinical trials. Huntsman Cancer Institute (HCI) located in Salt Lake City, Utah, is the only NCI-Designated Cancer Center in the Mountain West and a critical access point for clinical trials. Our catchment area includes six states and 525,000 square miles. Travel to large centers can be associated with financial toxicity and social stress which adversely affect health-related quality of life in MM. Beyond Salt Lake City boundaries is mostly considered rural for health access; additionally, patients living in these areas are at risk for being uninsured or underinsured. Herein we describe our enrollment for clinical trials as it pertains to rurality with consideration of insurance status. **Methods:** A list of enrolled subjects in MM or AL-amyloid clinical trials from January 2018 to April 2023 was compiled to evaluate geographical and rural enrollment patterns among these niche patient populations at HCI. A randomized identifier was created and patient information appended, including: zip code and residence distance to HCI, age, sex, and insurance status. Zip codes were used to determine county and deemed rural versus not rural according to the Federal Office of Rural Health Policy (FORHP). Descriptive statistics were utilized. **Results:** A total of 97 patients were enrolled in clinical trials; a majority being males (57%) and only 3% of enrollees having AL-amyloidosis. Medicare or Medicaid comprised 43%, private insurance 53%, and 4% were uninsured. Based on county of residence, 18% were rural while 82% were not. A majority of rural patients (65%) had Medicare and the remainder had private insurance. Amongst the 97 patients enrolled, the majority (52%) lived within 20 miles of the cancer center, and 73% of patients lived within 40 miles. Twelve percent of patients lived within 41-80 miles of the cancer center, whereas only 15% of patients enrolled on trials lived over 80 miles away. **Conclusions:** Our study shows that most patients with MM or AL-amyloid enrolled on trials at our NCI-designated cancer center in the Mountain West live within an 80-mile radius. With an understanding of historical patient demographics, we aim to improve access to our clinical trials in the next five years. This will be accomplished by increasing patient support group topic frequency about open clinical trials, expanding our trial portfolio, testimonies from existing trial patients within existing support groups, and increased utilization of our existing Rural Patient Navigator in trial screening processes. Future directions include research to better understand the reasons rural patients decline participation in clinical trials.

Practical management of patients with relapsed/refractory multiple myeloma receiving talquetamab, a GPRC5D×CD3 bispecific antibody: experience in monumenTAL-1

Donna Catamero[1], Kiah Purcell[2], Chloe Ray[2], Leora Giacoia[2], Sheryl Leahey[3], Patricia Born[4], Sandy Kruyswijk[5]

[1]Mount Sinai Health System, New York, NY, USA; [2]Mount Sinai School of Medicine, New York, NY, USA; [3]City of Hope National Medical Center, Duarte, CA, USA; [4]University Hospital Würzburg, Würzburg, Germany; [5]Amsterdam University Medical Center, Amsterdam, The Netherlands

Introduction: Talquetamab (tal) is a T-cell redirecting bispecific antibody targeting a novel antigen, G protein–coupled receptor family C group 5 member D (GPRC5D). Tal has shown overall response rates of >71% in patients with relapsed/refractory multiple myeloma (RRMM) in the MonumenTAL-1 study. Adverse events (AEs) reported with tal include those associated with T-cell redirection therapies as well as GPRC5D-related AEs. Here we provide guidance for administering tal and strategies for monitoring and managing AEs based on our experience in the MonumenTAL-1 study. **Methods:** MonumenTAL-1 (NCT03399799/NCT04634552) is an open-label, single-arm, phase 1/2 study of patients with RRMM evaluating the recommended phase 2 doses of subcutaneous tal at 0.4 mg/kg weekly and 0.8 mg/kg every other week. **Results:** Administration of tal includes initial "step-up" doses prior to the first full dose to mitigate risk of high-grade cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Similar to other bispecifics, these AEs appear early with tal and are generally mild to moderate. Patients should be premedicated appropriately and monitored closely for CRS/ICANS during step-up dosing and the first full dose. Infections are a common complication of MM; patients should be screened for infections before starting tal, receive prophylaxis as needed, and be monitored throughout treatment for infections. GPRC5D-related AEs, including dermatologic and oral toxicities, also tend to appear early, after the first few doses of tal. Dermatologic AEs (incidence ~30–73%), including rash and skin peeling, are relatively benign, not painful, self-limiting, and manageable with emollients; nail AEs (incidence ~54–63%), including nail thinning and loss, are mostly aesthetic but take time to resolve. Oral AEs (incidence ~71–77%),

treatment, and remains on maintenance therapy for ongoing CMV viremia. This asymptomatic patient was on a BsAB clinical trial; the other patients being surveilled did not cross the treatment threshold. **Conclusions:** Given the evolution of safety data and monitoring for novel treatments in RRMM, we updated our algorithm. As a result, nursing practice has elevated to quickly identifying patients at highest risk for developing PJP and CMV viremia and intervening appropriately. Prolonged treatment holds have been reduced due to this algorithm as evidenced by no new PJP infections and a small proportion of patients with mild CMV. In the future, we hope to refine best practices for CD4 and CMV titer monitoring and frequency in RRMM.

Practical management of patients with relapsed/refractory multiple myeloma receiving talquetamab, a GPRC5D×CD3 bispecific antibody: experience in monumenTAL-1

Donna Catamero[1], Kiah Purcell[2], Chloe Ray[2], Leora Giacoia[2], Sheryl Leahey[3], Patricia Born[4], Sandy Kruyswijk[5]

[1]Mount Sinai Health System, New York, NY, USA; [2]Mount Sinai School of Medicine, New York, NY, USA; [3]City of Hope National Medical Center, Duarte, CA, USA; [4]University Hospital Würzburg, Würzburg, Germany; [5]Amsterdam University Medical Center, Amsterdam, The Netherlands

Introduction: Talquetamab (tal) is a T-cell redirecting bispecific antibody targeting a novel antigen, G protein–coupled receptor family C group 5 member D (GPRC5D). Tal has shown overall response rates of >71% in patients with relapsed/refractory multiple myeloma (RRMM) in the MonumenTAL-1 study. Adverse events (AEs) reported with tal include those associated with T-cell redirection therapies as well as GPRC5D-related AEs. Here we provide guidance for administering tal and strategies for monitoring and managing AEs based on our experience in the MonumenTAL-1 study. **Methods:** MonumenTAL-1 (NCT03399799/NCT04634552) is an open-label, single-arm, phase 1/2 study of patients with RRMM evaluating the recommended phase 2 doses of subcutaneous tal at 0.4 mg/kg weekly and 0.8 mg/kg every other week. **Results:** Administration of tal includes initial "step-up" doses prior to the first full dose to mitigate risk of high-grade cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Similar to other bispecifics, these AEs appear early with tal and are generally mild to moderate. Patients should be premedicated appropriately and monitored closely for CRS/ICANS during step-up dosing and the first full dose. Infections are a common complication of MM; patients should be screened for infections before starting tal, receive prophylaxis as needed, and be monitored throughout treatment for infections. GPRC5D-related AEs, including dermatologic and oral toxicities, also tend to appear early, after the first few doses of tal. Dermatologic AEs (incidence ~30–73%), including rash and skin peeling, are relatively benign, not painful, self-limiting, and manageable with emollients; nail AEs (incidence ~54–63%), including nail thinning and loss, are mostly aesthetic but take time to resolve. Oral AEs (incidence ~71–77%),

including dysphagia (difficulty swallowing), dry mouth, and taste changes, tend to have longer duration and can affect patients' quality of life; patients generally experience taste alteration with dry mouth that may lead to difficulty swallowing, which in turn can lead to weight loss. Supportive measures may be utilized (eg, NaCl mouth rinse, artificial saliva spray, diet modification) but oral AEs are most successfully managed with dose modification. A multidisciplinary team, including dermatologists, dentists, and nutritionists, can be consulted to provide additional guidance on managing GPRC5D-associated AEs. Educating patients about what to expect and ensuring they report symptoms promptly is also key to managing AEs appropriately. In general, patients respond well to treatment, and GPRC5D-associated AEs improve over time, becoming more tolerable; notable reduction in AEs is seen with dose modification. **Conclusions:** Tal demonstrates responses in >71% of patients with RRMM, with a safety profile that can be clinically managed with appropriate identification, monitoring, and treatment to ensure patients receive optimal benefit of tal.

Introduction: Patients with relapsed/refractory multiple myeloma (RRMM) are at an increased risk of infection, which may compromise quality of life and treatment outcomes. Teclistamab is the only approved BCMA×CD3 bispecific antibody with a personalized, weight-based, and flexible dosing schedule for the treatment of triple-class exposed RRMM. In the MajesTEC-1 study, prophylaxis and management of infections with teclistamab were per institutional guidelines. We share our experience in managing patients treated with teclistamab to support nurses on the front line of patient care. **Methods:** Patients in MajesTEC-1 were screened for hepatitis B and C, and must have had no evidence of serious bacterial, viral, or fungal infections to initiate treatment with teclistamab, which was administered subcutaneously at a dose of 1.5 mg/kg once weekly after the approved step-up dosing schedule. At our institutions, all patients treated with teclistamab were up to date with vaccinations (eg, COVID-19, influenza, and pneumococcal) and received acyclovir or valacyclovir prophylaxis; additional antimicrobials (eg, sulfamethoxazole/trimethoprim for Pneumocystis jirovecii pneumonia prophylaxis) were given per individual center guidelines. We regularly assessed all patients for infection prior to each weekly teclistamab dose and performed complete blood counts, cytomegalovirus testing, and COVID antibody testing as needed. Patients were also asked to self-report any signs or symptoms of infection (eg, fever, chills, cough) to the hospital team. Infections were managed with antimicrobials and teclistamab dose delays as appropriate. Immunoglobulin G (IgG) levels were monitored every 4 weeks at our centers with intravenous IgG (IVIG) given every 3–6 weeks if levels fell below 400 mg/dL. Treatment-emergent neutropenia was managed with granulocyte colony-stimulating factor (G-CSF), although this was avoided during periods of high risk for cytokine release syndrome, eg, teclistamab step-up dosing. **Results:** In MajesTEC-1, infections occurred in 80.0% of patients, with grade 3/4 in 55.2% (most commonly COVID-19, respiratory infections, Pneumocystis jirovecii pneumonia, and viral infections) and deaths in 12.7%. Approximately 70% of patients had IgG < 400 mg/dL (overall, 46.1% received at least one dose of IVIG); 65.5% of patients had grade 3/4 neutropenia and 54.5% used G-CSF. **Conclusions:** Teclistamab should not be given in case of any active infection; therefore, partnership between nurses, physicians, and patients is essential to facilitate prompt identification, monitoring, and management of infections, including appropriate use of antimicrobial prophylaxis, IVIG, and G-CSF. In particular, we recommend that patients are educated on the importance of reporting early signs and symptoms of infections, and that nurses and care teams are prepared and trained to implement appropriate infection management strategies.

Managing cytokine release syndrome in relapsed/refractory multiple myeloma: experience with teclistamab in the MajesTEC-1 study

Donna Catamero[1], Patricia Blázquez Benito[2], Samantha Shenoy[3], Katherine Chastain[4], Sandy Kruyswijk[5]

[1]Mount Sinai Health System, New York, NY, USA; [2]University Hospital of Salamanca, Salamanca, Spain; [3]University of California, San Francisco, San Francisco, CA, USA; [4]Janssen Research & Development, Raritan, NJ, USA; [5]Amsterdam University Medical Center, Amsterdam, The Netherlands

Introduction: Cytokine release syndrome (CRS) is a systemic inflammatory response commonly associated with T-cell engagers. In the MajesTEC-1 study of teclistamab, the only approved BCMA×CD3 bispecific antibody with a personalized, weight-based, and flexible dosing schedule for the treatment of triple-class exposed relapsed/refractory multiple myeloma, CRS was effectively managed with pre-medication, step-up dosing, and prompt diagnosis and intervention (Martin et al, Cancer, 2023). As nurses are on the front line of patient care, recognizing CRS and responding with appropriate treatment are critical to mitigate risk of severe/life-threatening CRS. Here, we aim to support nurses with guidance on CRS diagnosis, monitoring, and management in patients receiving

including dysphagia (difficulty swallowing), dry mouth, and taste changes, tend to have longer duration and can affect patients' quality of life; patients generally experience taste alteration with dry mouth that may lead to difficulty swallowing, which in turn can lead to weight loss. Supportive measures may be utilized (eg, NaCl mouth rinse, artificial saliva spray, diet modification) but oral AEs are most successfully managed with dose modification. A multidisciplinary team, including dermatologists, dentists, and nutritionists, can be consulted to provide additional guidance on managing GPRC5D-associated AEs. Educating patients about what to expect and ensuring they report symptoms promptly is also key to managing AEs appropriately. In general, patients respond well to treatment, and GPRC5D-associated AEs improve over time, becoming more tolerable; notable reduction in AEs is seen with dose modification. **Conclusions:** Tal demonstrates responses in >71% of patients with RRMM, with a safety profile that can be clinically managed with appropriate identification, monitoring, and treatment to ensure patients receive optimal benefit of tal.

Managing cytokine release syndrome in relapsed/refractory multiple myeloma: experience with teclistamab in the MajesTEC-1 study

Donna Catamero[1], Patricia Blázquez Benito[2], Samantha Shenoy[3], Katherine Chastain[4], Sandy Kruyswijk[5]

[1]Mount Sinai Health System, New York, NY, USA; [2]University Hospital of Salamanca, Salamanca, Spain; [3]University of California, San Francisco, San Francisco, CA, USA; [4]Janssen Research & Development, Raritan, NJ, USA; [5]Amsterdam University Medical Center, Amsterdam, The Netherlands

Introduction: Cytokine release syndrome (CRS) is a systemic inflammatory response commonly associated with T-cell engagers. In the MajesTEC-1 study of teclistamab, the only approved BCMA×CD3 bispecific antibody with a personalized, weight-based, and flexible dosing schedule for the treatment of triple-class exposed relapsed/refractory multiple myeloma, CRS was effectively managed with pre-medication, step-up dosing, and prompt diagnosis and intervention (Martin et al, Cancer, 2023). As nurses are on the front line of patient care, recognizing CRS and responding with appropriate treatment are critical to mitigate risk of severe/life-threatening CRS. Here, we aim to support nurses with guidance on CRS diagnosis, monitoring, and management in patients receiving

teclistamab, based on the MajesTEC-1 experience. **Methods:** A step-up dosing schedule (0.06 and 0.3 mg/kg step-up doses before first treatment dose of 1.5 mg/kg subcutaneous teclistamab), requiring premedication with a corticosteroid, histamine-1 receptor antagonist, and antipyretic, was used to mitigate risk of high-grade CRS. Frequent vital sign observations (every 2–4 hours per institutional guidelines) by the inpatient nursing team during step-up dosing were required to monitor for CRS. CRS management was dependent on CRS severity but included tocilizumab (36.4% of patients), intravenous fluids (13.9%), low-flow oxygen (12.7%), steroids (8.5%), single vasopressor (0.6%), and other supportive measures, including antipyretics. **Results:** Overall, 72.1% of patients experienced CRS; all events were grade 1/2, except for one grade 3 event that occurred in the setting of an infection. Among patients with CRS, 96.6% experienced CRS during step-up dosing; thus, frequent monitoring during this period is critical. As common CRS symptoms (fever, hypoxia, chills, hypotension) can present with other conditions, a differential diagnosis is important to ensure that CRS is properly diagnosed and treated. CRS was monitored inpatient with vital signs checked frequently (every 2–4 hours) or continuously through wearable devices. Partnering with patients and physicians to recognize and report CRS symptoms early allowed for rapid intervention and transfer to intensive care where necessary. As infections can exacerbate CRS, patients should be examined for signs of infection, and all infections should be resolved before initiating teclistamab. In MajesTEC-1, tocilizumab could be considered for grade 1 CRS and was recommended for grade 2 events. At our institutions, tocilizumab was given for grade 1 CRS (either generally or if persistent), and no patient had recurrent CRS. **Conclusions:** Practical guidance is needed for nurses to recognize and monitor CRS and to anticipate when treatment and escalation are needed to ensure successful administration of teclistamab. Data previously presented at the 2023 Oncology Nursing Society (ONS) Annual Meeting.

Scrambler therapy for neuropathic pain: a systematic review of evidence in plasma cell disorders

Beth Faiman[1], Ruth Lagman[1], Susan McInnes[1], Kyle Neale[1], Chirag Patel[1], Laura Shoemaker[1], Renato Samala[1]

[1]Cleveland Clinic

Introduction: Research into the prevention and treatment of peripheral neuropathy (PN) is evident in other cancers and disease states but strategies are conspicuously absent in patients with plasma cell disorders (PCDs), such as multiple myeloma, and amyloidosis. Peripheral neuropathy occurs in PCD patients with prolonged exposure to neurotoxic therapies, such as bortezomib, and/or because of disease progression. This condition is often managed with medications (such as gabapentinoids and antidepressants) and non-pharmacologic treatments (such as transcutaneous electrical nerve stimulation and spinal cord stimulation) with varying degrees of efficacy. High-quality studies into PN treatments are desperately needed due to the major adverse impact these poorly understood complications have on the quality of life (QOL) and control of the disease. In recent years, Scrambler Therapy (ST) has emerged as an alternative non-pharmacologic intervention for treatment of neuropathic pain but emerging evidence supports its use in pain from other sources. ST is approved by the FDA as a non-invasive electro-analgesia device that aims to transform the information of pain into non-pain signals using the same pathways, ultimately resulting in remodulation of the pain system and retraining of the brain. The newest version is ST-5A with 5 channels that deliver low-intensity stimuli (max. 5 mA) generated by a completely automated treatment program. Previous studies have demonstrated ST efficacy, including in the treatment of chronic, opioid-resistant cases and chemotherapy-induced peripheral neuropathy (CIPN). Recently, our Department of Palliative and Supportive Care acquired an ST unit and began treating patients in January 2023. Thus, the aim of this systematic review was to detect gaps in the literature regarding the efficacy of ST for PCD pain and formulate recommendations for research. **Methods:** PubMed with MeSH was used to identify studies that met inclusion criteria using a pre-determined search strategy. A reference list of retrieved studies, Google Scholar, and clinicaltrials.gov database were used to verify that no relevant studies had been omitted. Data were extracted from the studies with a data extraction sheet. Qualitative analyses of the extracted data were undertaken. **Results:** Eighty-two references to ST were identified. Of these, 13 full-text papers including clinical trials were reviewed. Only one study reported findings in patients with amyloidosis, using the older MCA-5 device model, but no studies were conducted specifically in PCD using the newer ST-5A scrambler model. **Conclusions:** Peripheral neuropathy symptoms plague patients with chronic, but incurable conditions, such as PCD. This review sheds initial light on the need for further research of ST in PCD and specifically using the newest technology. Caution is needed in that due to the small sample sizes of the studies included, these findings cannot be generalized, yet provide direction for future symptom science studies.

A comparison of reach and effectiveness of live versus virtual case-based education for nurses

Beth Faiman[1], Donna Catamero[2], Tiffany Richards[3], Kimberly Noonan[4], Diane Moran[5], Michelle Faber[5], Joyce Divine[5]

[1]Cleveland Clinic Taussig Cancer Institute, Department of Hematology and Medical Oncology; [2]Mount Sinai Health System, New York, NY, USA; [3]University of Texas MD Anderson Cancer; [4]Dana-Farber Cancer Institute; [5]International Myeloma Foundation

Introduction: The expanding landscape of multiple myeloma (MM) treatment options, coupled with an emphasis on advocacy, highlights the need for nurses to have access to up-to-date education. To address the distinct educational needs of both in-person and e-education learners, 4 expert MM faculty developed educational content for a 1.5-hour symposium held in person at the Oncology Nursing Society Annual Congress in Los Angeles, California on April 28, 2022, and later available via a virtual, enduring format.

Here we present a comparative analysis of reach and effectiveness between the 2 formats for a case-based MM treatment continuing education intervention. **Methods:** To develop content, faculty participated in 13, 1-hr planning sessions from Jan 1-Apr28 2022. Faculty conducted literature reviews to include the most updated information, adopting a case study-based learning format and integrated updated educational content. Demographics, practice information, pre-/post-education surveys, and intent to change were administered to the 477 in-person attendees, and to 10,556 virtual enduring program participants from Jul 1–Dec 31, 2022. **Results:** The live program attendees were split between academic and community practice settings while more virtual attendees practiced in the community. The average number of patients with MM seen per month was 10.2 in-person vs 4.5 virtual. The virtual program attendees were estimated to impact 21,332 patients with MM per month, compared with 3,453 patients for the in-person program. Learning gains were reported across all domains in diagnosis, disparities, relapse workup, and immunotherapies (Figure 1). Of respondents polled during the in-person program 73% (N=371) reported, "Yes" they plan to make clinical changes to improve their effectiveness. 85% (N=327) reported a 'strong' or 'very strong' commitment to making planned changes, while 85% (N=318) of those reported a change plan to "be more mindful of my influence on myeloma patients" outcomes. In the virtual program (N=4087), 72% reported "Yes, I plan to make changes to improve my effectiveness as a healthcare team member" while 78% reported a 'strong' or 'very strong' commitment to change and 60% reported they plan to "be more mindful of my influence on myeloma patients' outcomes." **Conclusions:** While most learners at the in-person meeting were from the US and divided between academic and community practice, the virtual format was utilized by a higher % of community-based learners and attendees from outside the US. Results indicate both formats effectively reached audiences with learning gains across domains. A similar % of respondents in both groups intended to make changes to their practice. Both formats showed comparable levels of knowledge acquisition and competency development, suggesting the virtual enduring format is complementary to in-person education. Results underscore the effectiveness of live continuing education and the importance of e-education to meet the evolving educational needs of nurses.

Co-designing a pilot patient support program (PSP) for a multiple myeloma (MM) therapy prior to listing on the pharmaceutical benefits scheme

Emma-Jane Furphy[1], Hayley Beer[1,2], Laura Jones[1], Gareth Davidson[3], Nathan O'Donnell[3], Nirmal Lorensuhewa[4], Joanne Farrell[4], Tamara Etto[4], Michele Robbins[4]

[1]Myeloma Australia; [2]Peter MacCallum Cancer Centre; [3]Atlantis Health; [4]Antengene

Introduction: Myeloma Australia (MA), a non-profit support organisation, identified poor uptake of traditional pharmaceutical company facilitated patient support programs (PSPs) when the program is designed with a single drug focus and does not follow the patient beyond progression. MA together with Antengene (AUS) Pty Ltd, a biopharmaceutical company, co-designed a PSP for patients with relapsed/refractory MM (RRMM) who were prescribed XPOVIO® (selinexor) in combination with dexamethasone (Xd). Given that XPOVIO is a novel anti-myeloma drug available in Australia, the PSP aimed to enhance patient education and support their hospital-based treating teams for achieving optimal patient outcomes. **Methods:** Review of existing PSPs was conducted, including multi-disciplinary advisory boards including haematologists, nurses and pharmacists. MA and Antengene worked together with a behavioural change organisation, Atlantis Health, to review patients' key needs at the time of XPOVIO® therapy. The program designed would support patients at key time points throughout their treatment and beyond, that would be complimentary to the care provided by their hospital-based treating team. **Results:** 14 RRMM patients (8 male and 6 female) prescribed Xd via an access program were enrolled into the X-TEND program (age range 47-85 yrs). Patients received contact from a specialist MA nurse at baseline and at defined intervals. Average call duration was 20 mins. Topics discussed included management of adverse events, general physical wellbeing, and psychosocial support. Average time on XPOVIO was 141 days and patients could remain on the program once therapy has ceased. **Conclusions:** X-TEND is a comprehensive PSP that provides one-on-one bespoke support to patients on Xd regimen. It provides education on side-effect management, ensures the patient has a better understanding of their disease and offers unlimited emotional and psychosocial supportive care. The PSP has filled gaps that the hospital system is not able to fill. MA has plans to replicate this model with other myeloma therapies.

Introduction: Steroids remain a mainstay in multiple myeloma (MM) treatment, with significant side effects (SE). As no tool existed to monitor steroid SE in this population, we developed the SSQ-MM to inform clinical care. Pilot testing of the SSQ-MM demonstrated high levels of feasibility, acceptability, repeatability, and internal consistency. This paper presents preliminary findings of a multi-site study to test the clinical validity and reliability of the final version SSQ-MM. **Methods:** Clinical validity of the SSQ-MM was tested in a prospective, multi-centre, cross sectional study. MM patients attending participating haematology departments and taking steroids as part of MM treatment were invited to participate. The SSQ-MM, EORTC quality of life and MM Patient Reported Outcome Measures (PROM) (QLQ-C30 & MY20) were

Clinical validation of the steroid symptom questionnaire multiple myeloma (SSQ-MM) in a multi-centre study

Tracy King[1,2], Jacqueline Jagger[3], Claudia Rutherford[2], Louise Acret[2], Margaret-Ann Tait[2], Julija Sipavicius[4], Georgia McCaughan[5], Susan Stapleton[5], Kate White[2,6]

[1]Royal Prince Alfred Hospital; [2]The University of Sydney; [3]Central Coast Local Health District; [4]Royal North Shore Hospital; [5]St Vincent's Hospital, Sydney; [6]Sydney Local Health District

Introduction: Steroids remain a mainstay in multiple myeloma (MM) treatment, with significant side effects (SE). As no tool existed to monitor steroid SE in this population, we developed the SSQ-MM to inform clinical care. Pilot testing of the SSQ-MM demonstrated high levels of feasibility, acceptability, repeatability, and internal consistency. This paper presents preliminary findings of a multi-site study to test the clinical validity and reliability of the final version SSQ-MM. **Methods:** Clinical validity of the SSQ-MM was tested in a prospective, multi-centre, cross sectional study. MM patients attending participating haematology departments and taking steroids as part of MM treatment were invited to participate. The SSQ-MM, EORTC quality of life and MM Patient Reported Outcome Measures (PROM) (QLQ-C30 & MY20) were

administered together, with the SSQ-MM repeated 1-week later. Internal consistency reliability was tested with Cronbach's alpha >0.8 for individual patient decision-making. Test-retest using intraclass correlation coefficient >0.7 to test scale stability reliability. An estimated 200 patients are required to achieve statistical requirements. Clinical and demographic characteristics were collected. **Results:** To date, 109/200 patients have been recruited across four hospitals in Sydney, Australia. Participants were 45-86yrs, 57% male, with average 4yrs (range, 1mth to 22yrs) since diagnosis. More than half (65/109; 59.6%) completed the PROMs electronically. Average dexamethasone dose was 28mg weekly (range, 4 to 80), or 124mg per cycle (range, 12 to 180). The most common regimens were Lenalidomide & Bortezomib (29/109, 26.6%), Lenalidomide (24/109, 22%), Daratumumab & Bortezomib (15/109, 13.8%), or Carfilzomib (15/109, 13.8%) based. Cronbach's alpha at time points 1 (0.83) and 2 (0.84) showed internal consistency, and test-retest indicated the scale was stable (ICC: 0.844, 95%CI: 0.779 to 0.892; p< 0.001). The most frequently reported symptoms were disturbed sleep 100/109 (91.7%), loss of energy/fatigue 88/109 (80.7%), and trouble concentrating 87/109 (79.8%). Patients typically experienced 10 symptoms concurrently (range, 1 to 19), with 4 symptoms rated as severe (range, 0 to 12). Most frequently reported severe symptoms included disturbed sleep 73/109 (67 %), loss of energy/fatigue 55/109 (50.5%), and fragile skin/easy bruising 50/109 (45.9%), with disturbed sleep rated as most bothersome 53/109 (48.6%). **Conclusions:** The SSQ-MM currently demonstrates high levels of feasibility, acceptability, and reliability and is suitable for clinical use to manage steroid toxicity and improve treatment outcomes for MM patients. The study continues to evaluate convergent and discriminant validity by exploring relationships between similar and dissimilar constructs within EORTC QLQ-C30 and QLQ-MY20, enabling the SSQ-MM to be used in future clinical trials of steroid treatments for MM. A study characterising sleep disturbance in this patient group is underway.

NSP-10

Addressing the complex care needs of the individual with multiple myeloma (MM) and their family: contribution of advanced practice myeloma nurses

Kate White[1,2], Tracy King[1]

[1]Royal Prince Alfred Hospital, The University of Sydney; [2]Sydney Local Health District

Introduction: Australia has the highest incidence of multiple myeloma (MM) internationally, with a projected increase of 42% by the year 2040. This projected increase combined with changes to approaches to treatment, management of associated toxicities, in a predominantly older patient cohort has highlighted a need to examine new approaches to the delivery of care for this incurable disease. To inform the development of new models of care delivery, a MM Specialist Group commissioned the development of a White Paper. **Methods:** A systematic review of advance nurse practice roles in cancer and haematology was undertaken. Indepth interviews with haematology health care professionals (HCP) explored their perspective of gaps in current delivery of care models, potential approaches to address these, and current challenges in delivery clinical MM care. Fifteen haematology medical and nursing specialists participated in the telephone interviews. These were thematically analysed. **Results:** Systematic review of studies of advanced practice nurse (APN) roles consistently report positive findings. Studies focused on three areas: comparison of medical versus nurse delivery of care (replacing component of a medical role); development of new nursing role to improve patient outcomes; and nurse led models of care. While the quality of the research was variable, studies consistently report positive findings in support of APN roles benefiting patient outcomes and improved service delivery. Improvements were reported in patient symptom management, emotional wellbeing, being informed, earlier referral to palliative care, increased communication with primary care. The review highlighted the need to establish consistent nomenclature and scope of nursing practice in line with APN roles. Interviews with stakeholders highlighted the perception addressing the increasingly complex nature of MM patients, treatment optimization needed to be a priority, and that currents service delivery approaches were not designed or resourced to meet the increasingly complexity associated with the care of those impacted by MM. HCP identified the heterogeneous and unpredictable nature of the disease establishing MM as a complex disease to treat with transition to lifelong active treatments, a compounding toxicity profile, and comorbidities associated with an older population. **Conclusions:** Drawing on these findings the patient centred Model for Complex Myeloma Care incorporates components to optimize care; MM supportive care, tailored education, advocacy, coaching, access, assessment, and monitoring been developed. The MM White Paper recommends establishment of MM specific APN roles to provide tailored specialist care and need for service planning to address the growing incidence in MM. Further exploration of older MM specific needs as recommended, and this work is currently underway.

The most frequently reported symptoms were disturbed sleep 100/109 (91.7%), loss of energy/fatigue 88/109 (80.7%), and trouble concentrating 87/109 (79.8%). Patients typically experienced 10 symptoms concurrently (range, 1 to 19), with 4 symptoms rated as severe (range, 0 to 12). Most frequently reported severe symptoms included disturbed sleep 73/109 (67 %), loss of energy/fatigue 55/109 (50.5%), and fragile skin/easy bruising 50/109 (45.9%), with disturbed sleep rated as most bothersome 53/109 (48.6%). **Conclusions:** The SSQ-MM currently demonstrates high levels of feasibility, acceptability, and reliability and is suitable for clinical use to manage steroid toxicity and improve treatment outcomes for MM patients. The study continues to evaluate convergent and discriminant validity by exploring relationships between similar and dissimilar constructs within EORTC QLQ-C30 and QLQ-MY20, enabling the SSQ-MM to be used in future clinical trials of steroid treatments for MM. A study characterising sleep disturbance in this patient group is underway.

Addressing the complex care needs of the individual with multiple myeloma (MM) and their family: contribution of advanced practice myeloma nurses

Kate White[1,2], Tracy King[1]

[1]Royal Prince Alfred Hospital, The University of Sydney; [2]Sydney Local Health District

Introduction: Australia has the highest incidence of multiple myeloma (MM) internationally, with a projected increase of 42% by the year 2040. This projected increase combined with changes to approaches to treatment, management of associated toxicities, in a predominantly older patient cohort has highlighted a need to examine new approaches to the delivery of care for this incurable disease. To inform the development of new models of care delivery, a MM Specialist Group commissioned the development of a White Paper. **Methods:** A systematic review of advance nurse practice roles in cancer and haematology was undertaken. Indepth interviews with haematology health care professionals (HCP) explored their perspective of gaps in current delivery of care models, potential approaches to address these, and current challenges in delivery clinical MM care. Fifteen haematology medical and nursing specialists participated in the telephone interviews. These were thematically analysed. **Results:** Systematic review of studies of advanced practice nurse (APN) roles consistently report positive findings. Studies focused on three areas: comparison of medical versus nurse delivery of care (replacing component of a medical role); development of new nursing role to improve patient outcomes; and nurse led models of care. While the quality of the research was variable, studies consistently report positive findings in support of APN roles benefiting patient outcomes and improved service delivery. Improvements were reported in patient symptom management, emotional wellbeing, being informed, earlier referral to palliative care, increased communication with primary care. The review highlighted the need to establish consistent nomenclature and scope of nursing practice in line with APN roles. Interviews with stakeholders highlighted the perception addressing the increasingly complex nature of MM patients, treatment optimization needed to be a priority, and that currents service delivery approaches were not designed or resourced to meet the increasingly complexity associated with the care of those impacted by MM. HCP identified the heterogeneous and unpredictable nature of the disease establishing MM as a complex disease to treat with transition to lifelong active treatments, a compounding toxicity profile, and comorbidities associated with an older population. **Conclusions:** Drawing on these findings the patient centred Model for Complex Myeloma Care incorporates components to optimize care; MM supportive care, tailored education, advocacy, coaching, access, assessment, and monitoring been developed. The MM White Paper recommends establishment of MM specific APN roles to provide tailored specialist care and need for service planning to address the growing incidence in MM. Further exploration of older MM specific needs as recommended, and this work is currently underway.

Haematology society of Australia & New Zealand myeloma specialists practice network (MSPN) Consensus recommendations on supportive care for patients with multiple myeloma receiving selinexor

Tracy King[1,2], Jacqueline Jagger[3], Carmel Woodrow[4], Jessica Demajo[5], Hayley Beer[5,6], Daniela Klarica[7], Alicia Snowden[8], Kate White[2,9], Donna Catamero[10], Hang Quach[11]

[1]Royal Prince Alfred Hospital; [2]The University of Sydney; [3]Central Coast Local Health District; [4]Princess Alexandra Hospital; [5]Peter MacCallum Cancer Centre; [6]Myeloma Australia; [7]Alfred Health; [8]Precision Haematology; [9]Sydney Local Health District; [10]Mount Sinai Health System, New York, NY, USA; [11]St Vincent's Hospital Melbourne, University of Melbourne, VIC, Australia

Introduction: Selinexor is a first in class, oral, selective inhibitor of nuclear export (SINE) that is approved for the treatment of relapsed refractory multiple myeloma (RRMM). Selinexor has a

significantly different toxicity profile to other MM treatments yet has not been included in current supportive care guidelines. Patients receiving selinexor may be heavily pre-treated, with significant disease and treatment related morbidities, and have comorbidities of an older patient group. Early recognition and implementation of supportive care interventions is critical to minimise selinexor-related toxicities and reduce risk of subsequent discontinuation of therapy. **Aim:** To provide guidance for nurses to deliver best supportive care to those receiving selinexor through development of living consensus recommendations. **Methods:** The approach to developing consensus recommendations when there is limited research evidence was followed. A Selinexor Expert Advisory Group (SEAG) was established, all available published research, including selinexor licensing clinical trial data and papers focused on dosing, toxicity and management were examined. In addition, optimal supportive care, national and international guidelines associated with cancer supportive care were identified and reviewed. Draft consensus recommendations were developed, and a formal consensus process followed with SEAG. Draft recommendations were reviewed by an international MM nurse leader with experience in managing selinexor toxicities, a haematologist, and an academic nurse researcher prior to presentation to the M-SPN membership. Feedback from members was minor and incorporated into the final document. **Results:** Consensus Recommendations: Three core areas: 1. Patient and carer education prior to commencing treatment focusing on different symptom profile, importance of recognising and early reporting of symptoms, adherence to medications to reduce toxicities, concurrent supportive medications in an often medically fragile population. 2. Prompt and proactive symptom management in the first few cycles of therapy can reduce the risk of treatment discontinuation due to toxicity. 3. Prompt dose reduction in presence of therapy-related adverse events (TRAEs) with a 'go slow and low' approach can further help patients better adjust to therapy. The recommendations include brief information about selinexor indication, dosing/reductions, TRAE incidence and management of common toxicities, treatment checklist, links to 3rd party consumer information and patient treatment calendars, previously developed by our group https://rego.interact.technology/myetx/. **Conclusions:** Such level IV evidence that provides grade C recommendations provides useful evidence where data is lacking. This consensus guideline is important particularly as selinexor is reimbursed for the treatment of RRMM in Australia and will be updated regularly. Access @ www.hsanz.org.au.

Multiple myeloma and disparate populations: the path forward

Rebecca Lu[1], Joseph Tariman[2], Donna Catamero[3], Michaela Hillengass[4], Kimberly Noonan[5]

[1]MD Anderson; [2]Rutgers University; [3]Mount Sinai Health System, New York, NY, USA; [4]Roswell Park Comprehensive Cancer Center; [5]Dana-Farber Cancer Institute

Introduction: It is a well-known and disturbing fact that racial and ethnic minority populations with multiple myeloma (MM) are often underrepresented, especially in clinical trials. In fact, some studies report less than 4% of patients of African American descent will enroll in therapeutic trials1 and though there is opportunity to receive novel standard of care treatments, minority populations are still underserved. With this knowledge, an international group of MM nursing experts convened in September 2021 to discuss barriers that hinder equitable access to care and provide strategic solutions. Better understanding of diverse populations is critical for nurses and advanced practice providers to effectively provide care. **Methods:** In order to identify the prevalent groups impacted by disparity and barriers to equitable treatments, a literature review through PubMed was conducted using the search terms of myeloma, bias, diversity, inequity, clinical trial, sexual orientation, and disparity. A total of 180 articles were identified and from those, 54 were excluded as they did not involve MM patients and 37 were excluded as they did cover disparity in MM. **Results:** The search identified key disparities that affect patient access to treatment and care including race, age, socioeconomic status, and sexual preference/orientation. These disparities profoundly affect patient care and the effect of clinical trials, especially as investigational drugs are administered in real world setting. Based on literature review, authors synthesized the information to provide recommendations to better inform the nurse and advanced practice provider of strategies to increase trial participation for diverse populations. **Gap and proposed intervention:** Lack of healthcare provider education regarding existing disparities: 1. Provide ongoing education. 2. Identify and address barriers. 3. Provide resources on diversity and implicit bias. Lack of community awareness of clinical trials: 1. Provide clinical trial education directly to communities. 2. Establish relationships to foster trust. 3. Consider logistical challenges for patients. Lack of access to clinical trials for rural communities: 1. Develop outreach programs. 2. Utilize local laboratories and facilities to decrease travel burden. 3. Collaborate with sponsors to provide greater financial assistance. Lack of inclusivity in clinical trials: 1. Incorporate gender-neutral terminologies through consent and questionnaires. **Conclusions:** The lack of representation from various ethnic backgrounds in clinical trials ultimately impacts the treatment for all MM patients. Identifying and creating realistic strategies to address barriers to diversity in trial enrollment is a crucial step to advancing equity among MM patients. Based on the review the group developed evidenced based recommendations to equip health care providers to create an equitable therapy plan for MM patients with plans to publish full recommendations in a peer-reviewed journal.

Multiple myeloma: validation of the values and preferences elicitation questionnaire – cure and survival preference scale (VPEQ-CSPS)

Anastasiia Savchenko[1], Alexandria Kohon[1], Joseph Tariman[2], Shannon Simonovich[1], Thomas Dahan[2], Jessica Bishop-Royse[3]

[1]DePaul University; [2]Rutgers University; [3]Rush University

Introduction: With the emergence of many novel therapies, the treatment decisions for multiple myeloma (MM) are increasingly

guided by concerns of quality of life, achievement of cancer-free remission, living a longer overall survival, and a relentless search for a cure; however, the impact of these various treatment options on patients' choices and lives is mainly unknown. Oncology clinicians face the challenge of uncovering their patient's preferences and values and putting them into the actual treatment decision-making. **Purpose:** This study examined the psychometric properties of the Values and Preferences Elicitation Questionnaire-Cure and Survival Preference Scale (VPEQ-CSPS) instrument. **Methods:** The VPEQ-CSPS instrument was deployed using an anonymous Qualtrics online survey to patients diagnosed with MM within the network of International Myeloma Foundation (IMF) online patient support groups across the US. One hundred seventy-four (N=174) valid responses were obtained and used to examine the validity and reliability of the VPEQ-CSPS. **Results:** Exploratory factor analysis (EFA) revealed a Kaiser-Meyer-Olkin value of 0.72 indicating excellent sample adequacy and a statistically significant Bartlett's test of sphericity ($p < 0.001$) indicating significant correlations among the variables of the dataset to conduct the EFA. The internal consistency coefficients indicated high reliability of the instrument with Cronbach's alpha value at 0.80. The EFA and parallel analysis revealed the 5-item VPEQ-CSPS as a valid and reliable unidimensional scale that can be used by oncology clinicians to elicit their patient's personal values and preferences and achieve shared decision-making for myeloma treatment decisions. **Conclusions:** This study has demonstrated that VPEQ-CSPS is a 5-item unidimensional instrument with strong psychometric properties designed to elicit patient values and preferences for remission, survival, and cure. It addresses the communication gap during cancer treatment decision-making for MM. The information and data that the VPEQ-CSPS can elicit are essential to SDM and patient-centered care in patients with MM.

Project to improve volume of treatment and satisfaction (PIVOTS): optimizing physician and advanced practice provider workflow

Samuel Shewan[1], Mary Steinbach[1], Kelley Julian[2], Matthew Whooley[3], Carrie Bellerive[3], Zachary Francom[3], Douglas Sborov[3]

[1]Division of Hematology, Department of Internal Medicine, University of Utah Huntsman Cancer Institute; [2]Department of Pharmacy, University of Utah Hospitals and Clinics, Huntsman Cancer Institute; [3]Huntsman Cancer Institute at the University of Utah

Introduction: Huntsman Cancer Institute Plasma Cell Dyscrasia (PCD) Program is the primary referral center in the Mountain West. In 2021, we reported on a project to improve our care model to optimize clinical efficiency. Here we provide an update on this quality improvement project. We hypothesized that utilizing a contemporary clinical model would improve efficiency and Relative Value Unit (RVU) generation, enhance job satisfaction for all clinical team members while maintaining high patient satisfaction scores. This model, called Project to Improve Volume of Treatment and Satisfaction (PIVOTS) is focused on 4 fundamental pillars: 1) Modifying physician and APP clinic templates to optimize daily clinic volumes; 2) Establishing specific "divisions of labor" for patient follow-up; 3) Standardization of post-autologous transplant follow-up; and 4) Standardization of documentation practices via standardized note templates and intelligent text. The goal of this project was to improve our practice model to optimize patient care, productivity and team morale. **Methods:** Clinic template adjustments: Physician schedule templates included all New Patient Visits (NPV), follow-up visits with disease reassessment or treatment change, and visits per patient request. We eliminated the ability to double book on the MD schedule. There were defined instances for shared MD/APC visits: NPV with active MM, transplant consent, and treatment change or progression. Independent APP schedule templates included surveillance visits, clinical trial visits, and post-ASCT. The general approach is that patients with well controlled myeloma alternate between the MD and APP schedule on a 2 and 4-month or 3 and 6-month basis. To maximize efficiency, note templates and intelligent text were standardized for all physicians and APPs in the 6 months prior to starting PIVOTS. **Results:** Three outcome measures were defined before the start of the project based on our hypothesis: 1) Employee Satisfaction Rating; 2) APP wRVUs; and 3) Patient Satisfaction. Each outcome was assessed quarterly between May 2021 and May 2022. As measured from a survey, employee satisfaction improved from 50% to 71%. APP wRVUs increased from 1427 to 2397 per APC. Patient satisfaction scores based on the likelihood to recommend practice from the Press Ganey survey improved from 93% to 98%. **Conclusions:** Implementing PIVOTS has increased clinical efficiency, improved workforce satisfaction, and improved patient satisfaction scores. Importantly, these successes occurred during the COVID pandemic and during a period of growth in which clinic volumes increased > 100% between 2019 and 2022. While PIVOTS was piloted for a single physician schedule template, we now use this model for all clinical faculty in the PCD Program. Our outcomes justify the ongoing application of PIVOTS and we believe that "pivoting" patients between independent physician and APP schedules allows for significant workflow flexibility and allows our APPs to function at the top of their licensure.
